Your residence was on the sandy lands of the tide-water, where corn was the staple crop; but Providence cast my lot upon the green belt of the Blue Ridge, in a section, even then, rapidly improving in its agriculture. And I well remember, that the most usual sights in July and August, were large fields of clover subverted by the ploughshare, and the carts and wains all busily engaged in spreading the fertilizing produce of the stable and farm-pen, over those portions of the field which were more scantily covered with clover; and even those farmers who had not advanced to clover, were still anxious to reap the benefits of manuring and fallowing. And, as hope is more exciting than enjoyment, many hurried into those operations without even securing the previous crop, thinking less of the $2,000 they could get for it, than the $4,000 expected for the next year's produce; and I have often seen the coming crop covering those fallow fields with as bright a green as the clover which had so lately clad them, whilst the weather-beaten shocks stood amongst the rank stubble of the late harvest. But when our wise rulers took it into their heads that we must make every thing we wanted at home, and our hoodwinked farmers took up the idea, that to buy nothing was the best way to get rich, without reflecting that others must follow our example, they soon found that their barns were loaded with grain, laid up for many years; and, like the man in the parable, said "soul take thy rest." They then found that fallowing was a very laborious and expensive business; that the crop was very uncertain, and apt to be destroyed by the blue grass. For now they could not think of crossing their fallow, which was thought an expedient operation when wheat brought 9s. to 12s. a bushel; the crack of the whip, and shrill whistle of the driver, no longer impelled the patient ox with his fertilizing load; the weather was too hot in July and August; and the manure either wasted in the heap, or was all expended on tobacco, corn, or top-dressing.

The domestic market, which we sacrificed so much to gain, came at last; but it was not for wheat, but corn, which of course commanded the chief care and labor of the husbandman.

Now I would say to my brother farmers, resume those good old habits. This is the proper season. Select some field, or portion of one, of good land; not some worn-out gall, too poor for corn. Plough it well before the 1st September, if practicable, and re-plough it in that month, if necessary. Scatter all the manure you can raise, on the poorest part, and seed it well in the month of October; early, if in the upper part of the state, late in the month, if below. Plough or harrow in the wheat; but, at any rate, finish with a good smooth harrowing. If any part is inclined to be too wet, water-furrow it well. If your wheat has any smut, soak it in a strong brine, and roll in quick-lime immediately before seeding; and then pray to Heaven for a good harvest. As to your corn land, sow only that which is good, and no more than you can prepare well, and in good time; put the balance in oats. No preparation is good, unless the wheat is put in regularly at a suitable depth, and the soil well pulverized. The wheat ought never to be sown without some previous work; the land may be ploughed up with two horses, and this is best on flat land which requires bedding. But on dry land, I think the best mode is to cut the stalks off with a hoe, (not a knife, which leaves them too high;) pile or remove them. Plough up the stubbles, by running a furrow with a one or two-horse plough. Harrow the land crosswise or diagonally. Sow the wheat, plough it in with small ploughs, and harrow again. This will make the land almost as fine as a plant-bed; and although it is more trouble, if the wheat turns out well, you will be paid; and if not, it would certainly have been worse with a worse preparation. As soon as the crop is seeded, begin to lay plans and make preparations for putting in your next crop in the same or a better manner; and if your crops fail, my word for it, "you may thank God that your neighbors' are no better."

RED LAND.

RETARDED ACTION OF GYPSUM.

To the Editor of the Farmers' Register.

Some time last year I communicated the fact, that the effect of plaster, applied to the young clover soon after it came up, was not perceptible. I concluded that the soil either did not need that manure, or that the plaster was not genuine. But I am gratified to state that that plaster, though apparently useless last year, has manifested its efficacy in the most striking manner this, in so much that the bed of twenty feet width through a large lot, which was left unplastered, looks, at a little distance, as if it had been mowed, while there is a tall and luxuriant growth of clover on both sides of it. I believe that experiments in plaster, and other things, often prove abortive for the want of the unremitted personal attention of farmers to the application of them, and to the not following them out by the nicest and most careful personal inspection and comparison.

ON PISE BUILDINGS.

To the distressed inhabitants of the city of Charleston.

Seeing from the act of the legislature, as well as from the ordinance of our city council, that in future we are restricted to the use of incombustible materials in erecting our buildings, and knowing as I do the high price of such, and the difficulty of getting them at so high a price, I would suggest the use of *pisé*, or rammed clay walls. This mode of building is of great antiquity, and brought to such perfection in the country about the beautiful city of Lyons, in France, as to appear like elegant palaces, some of which are known to have stood three hundred years. But to be concise on this subject: I have just erected the walls, and covered in a house of 48 feet long by 24 wide, containing six large rooms, and three wide passages; and though built under many difficulties, which I had to surmount as I went on, yet it will bear comparison with any brick house of the same size, and was built in nine months by two men only, (who hired out at $10 per month before employed on this work,) assisted by a black country carpenter for three weeks. From the experience I have gained in the erection of this house, I can with confidence recommend (if my directions are followed) the use of *pisé buildings;* viz.: The foundation must be stone or brick, raised twelve to eighteen inches above the ground. The mould, which is very simple, must be a piece of 3 by 4 scantling, laid across the foundation, with a mortice at each end, describing the width of your wall, allowing for the thickness of the boards that are to stand on their edges, with their sides to the studs of scantling, standing in the mortices of the transverse scantling already mentioned, and capped with a piece of the same width; these studs to be erected three or four feet apart. The flooring-boards intended for the house, and which require seasoning, will just answer for this purpose, and will not be the least injured from this use, but better seasoned. They must be reduced to one thickness, and cut with a mitre at one end to meet at the corners, clasped with tin or sheet iron clasps, secured with small screws. These may be taken off every other course, and used as before. In this mould so formed, lay six inches of clay, as dry as you can procure it, (I never found it too dry,) and commence ramming, with a rammer beveled from a square of six inches, to one inch, all on one side. The pisadore (who is the rammer) finding it will not yield more to this rammer, then commences with a square rammer, till it rebounds briskly from the wall; he then continues filling in, continuing the same process till the boards are full, and he lays another board on the edge of that just finished, and continues this process until the story is raised to receive the joists. These are laid on a piece of scantling, 3 by 4, laid along in the mould, and each end is well dove-tailed. This being effected, I would recommend that the mould be taken apart from the wall; it will be found an equal continued surface, resembling a piece cut out of a rock, of the color of the clay. If this has any blemishes (or inequalities of surface) from the clay sticking to the mould, they can be immediately remedied by a plaster made of the same clay, with a mixture of cotton or hair. This being done, lay on the whole wall a coat of linseed oil. It will immediately sink in, and form an indurator, that will convert the surface to a crust of putty, impervious to rain, or any kind of moisture. After you have given the wall a coat or two of the oil, you may paint it of any color you wish, which it will show and retain, with the greatest brilliancy. Then erect your mould on the next story, and continue as before, laying (which I forgot to mention) your door and window jambs plumb in their proper places in the mould, as you go along. This mould possesses many advantages over the one which I described in my former article in the Agriculturist. It turns out the work in one continued mass, as if chiseled from a rock, and by this the work is reduced to three-fourths of the labor, and much more planished and perpendicular. In this manner, a pisé house can be built as elegant, durable, strong and incombustible, as of any other material allowed to be used. Its expense will depend much on the locality and vicinity of the clay, to the place it is erected. Having the clay at hand, my pisadore (or rammer) and one attendant, carried up sixteen inches of a wall, sixteen inches thick, in four days, all round a house, 48 feet long, and 24 feet wide. Now, if to build such a wall sixteen inches high, requires four days, how many days will it take to build it thirty-six feet high, the full height of a three-story house? Answer 108 days; which, at one dollar per day, would be equal to $216.

A brick house of this size would require 100,000 bricks, which at $15 per M., will amount to - -	$1500 00
Lime at 25 bushels per M., is 2500 bushels, at 20 cents, - - -	500 00
Laying the bricks at $4 per M., is -	400 00
Cost of the walls of the dwelling house only, - - - - -	$2400 00
Deduct the price of building the pisé house, - - - - - -	216 00
In favor of the pisé house, - -	$2184 00

But this is not all, for in a brick house you have to build a wood one within to make it fit to be inhabited; plaster and studs, laths, lime, nails and stucco, will amount to $1200, making the round sum of $3384. In opposition to this, I will state, the pisé walls require no plaster, but only to be smoothed and painted plain, or penciled, as taste may dictate. The pisé house being painted as it comes out of the mould, is fit to be inhabited as soon as finished.

But the difficulty of procuring clay is objected to. This will cease when we are informed, that all the bluffs about our harbor and rivers, contain it in abundance, and may be wafted over in lighters, and sold at a low price. Our harbor, and the rivers and creeks around us, contain inexhaustible banks of dead shells, which, if rammed in such a mould, will produce a fine wall equal to Tabby, well known to many of us. The banks of Ashley river abound in a concretion of calcareous matter fit for such buildings. To this important hint I call your attention. The doctrine that I have been endeavoring to inculcate, admits of the clearest demonstration, *actual experiment*. Take a box of a handy size, ram it with clay as described. When so filled and rammed, turn it up on a board, and lay it in the sun to dry, so as the box or mould may be lifted off without injury to the pisé-ed work. When dry, indurate it with linseed oil, and when it is dry, paint it on either side with any color you please. This experiment will satisfy you of the strength of the walls, the effects of the oil as an indurator, and the beautiful appearance of the paint.

I remain, with best wishes, yours, &c.

BARTH W. CARROLL.

From the Tennessee Farmer.

BEAVER OF NORTH AMERICA.

The natural habits of the beaver are topics so generally, though often so imperfectly handled, that we will rather speak at present of the manners which it is found to display in a domestic state, and of one or two other particulars less generally known.

We have domesticated certain animals, and most of those only to a certain extent, and are therefore apt to fancy that those are the only animals susceptible of domestication, and that they surpass all others in sagacity and companionable affections. But there is a very long list indeed, of animals, apparently the last to be thought of for domestication, but which, nevertheless, would please, and be pleased, if they, like others, lay in our bosoms, ate out of our dish, and sat at our firesides, and that would make manifest their understanding, and more than answer our caresses. An example presents itself in the beaver, whose habits in domesticity are pictured by a North American trader.

"I have kept several beavers," says Hearne, "till they became so domesticated as to answer to their name, and to follow those to whom they are accustomed, in the same manner as a dog would do, and they were as much pleased at being fondled as any animal I ever saw. In cold weather they were the constant companions of the Indian women and children, and were so fond of their company, that when the Indians were absent for any considerable time, the beavers discovered great signs of uneasiness; and, on their return, showed equal marks of pleasure, by fondling them, crawling into their laps, lying on their backs, sitting like a squirrel, and behaving like children who see their parents but seldom. In general, during the winter, they lived on the same food as the women did, and were remarkably fond of rice and plum-pudding: they would eat partridges and fresh venison very freely, but I never tried them with fish, though I have heard that they will at times prey on them. In fact, there are few granivorous animals that may not be brought to be carnivorous."

Of the things *usually* eaten by the beaver, the same writer gives the following account:—"Their food consists of a large root, something resembling a cabbage stalk, which grows at the bottom of the lakes and rivers. They also eat the bark of trees, particularly those of the poplar, birch, and willow; but the ice preventing them from getting to the land in the winter, they have not any bark to feed on in that season, except that of such sticks as they cut down in summer, and throw into the water opposite the doors of their houses; and as they generally eat a great deal, the roots above-mentioned constitute a principal part of their food during the winter. In summer they vary their diet, by eating different kinds of herbage, and such berries as grow near their haunts."

Beavers having returned in considerable numbers to Nottoway river and its tributaries, Mr. Ruffin, of the Farmers' Register, suggests the propriety of an experiment to domesticate them, with a view to the annual procurance of their rich furs, without destroying their lives. As this inoffensive and valuable animal is rapidly disappearing before the stratagems of the trapper, and the march of civilisation, this resort may become necessary, if practicable, and might perhaps turn out to be a profitable enterprise.

ED. TENN. FARMER.

From the Columbia Telescope.

MANURES.

Mr. Johnston—In Ruffin's Farmers' Register for May, 1838, p. 111, is an extract from a letter by Larduer Vanuxem, esq., formerly my aid in the college here, giving a very brief account of the localities of what he terms *shell marl*, in South Carolina, viz.: at the Santee canal, Eutaw Springs, Dr. Jameson's, near Orangeburgh Court House, Mr. Darby's, in St. Mathew's, at Godfrey's ferry, on the Pedee river, on the Edisto, &c. To which I have to add, a locality two miles south of Darlington Court House. *Marle*, technically, is a soil composed of sand, clay, and limestone, where the latter earth is in the proportion of one-third or more. I have reason to believe that all the localities consist principally of limestone, with various proportions of sand, but very small quantity of clay, or argillaceous earth.

My son brought me, a short time ago, a specimen of the shells and soil from the great oyster bank on the Santee, which I believe extends eight or ten miles. I have also received from Judge D. Johnson, a specimen of the shell marl near Darlington Court House. I regard all these, from the character of the shells in them, to belong to the tertiary formation—in modern phraseology, antediluvian.

Of the specimen from Santee, I took 100 grains of an oyster shell, (of an extinct species.) I dissolved it in muriatic acid, and about 5 per cent. of sand remained undissolved. I threw down all the limestone with carbonate of potash, boiling the solution to drive away any excess of carbonic acid, which is apt to keep limestone in solution. The liquor being filtered, and the residuum dried and weighed, furnished the expected proportion of limestone.

I took the earth with which the inside of the shell was filled up. I dissolved it as before, procuring about 90 per cent. of limestone. The residuum was chiefly sand, with but little clay-earth.

I took 100 grains of the common gravelly soil furnished me by Judge D. Johnson, from Darlington Court House vicinity. I rejected all the larger fragments of shells, taking what appeared to be the soil. I treated it as before, with muriatic acid, which dissolved perfectly 75 per cent. of the gravelly soil, leaving (when dried perfectly and weighed) 25 per cent. of soil, almost entirely sand, undissolved.

Here, then, in various parts of our state, are deposits of shell limestone, just as valuable for manure as any other whatever, to sandy, to clayey, or to an intermixture of sandy and clayey soil. A source of wealth that is of very great extent and very great value.

Limestone in Europe is applied when burnt into lime, sometimes to the amount of 300 bushels per acre. Twenty hundred weight of limestone ought to be exposed to fire in the kiln, till it will yield but eleven hundred weight, or more accurately from 43 to 44 per cent. of carbonic acid ought to be driven off by the heat; else the lime is imperfectly burnt, and will not make good mortar. When laid and slacked upon the land, it regains from the air about 30 per cent. of carbonic acid in about 10 days, and is gradually changed into limestone again. Hence the necessity of keeping lime from the air, which is to be used as a cement; hence, too, powdered limestone may be as good as lime in most cases. I would, therefore, were I a farmer, merely grind and screen the shell marl, without burning it, and put at least 300 or 350 bushels of the screened earth per acre, on the land. This will form a good constitution of soil, and will permanently prove useful. I should deem 400 bushels per acre, on sandy soils, not too much, and the addition of clay will add to the productive power of the mixture thus made. But as I am not a practical farmer, I say this with deference to the judgment of those who are.

I am, &c.

THOMAS COOPER, M. D.

From the Farmers' Cabinet.

CAPONS.

Auburn, Frederick Co., Md. Nov. 23, 1837.

I very much fear you will begin to think me either an epicure or the son of an epicure, it being only a short time since that I served you up a mess of bacon, and now I come with a dish of fowl. It has been said, it is not good for man to be alone. Bacon, although good alone, is very much better when accompanied with a good, round, fat pullet. But it is not a pullet that I am about to serve up to you at present, but her brother, though in an altered from, as you will learn in the sequel. It is a fact known to every traveller, that there is no dish presented before him half so often as that of chicken, served up in every form of which it is capable, broiled, fried, stewed, baked, or boiled; and it is a fact equally well known, that there is no dish so often turned away untasted, in consequence of its disgusting appearance of bad culinary preparations. I allude of course to such as we too frequently meet with on our public tables and watering places, (Bedford itself not excepted.) How often are the ears of the hungry and weary traveller assailed the moment the stage draws up to the inn, by the dying shrieks of the rooster that had but the moment before been picking up a scanty subsistence from the dunghill, and in a few moments more graces the head of the table, looking more like that well known waterfowl, vulgarly called a fly-up-the-creek, which is indebted alone to the length of its legs and neck for a subsistence, than what it really is. But I have promised to give you something even better than a fat pullet, and I shall now proceed to serve it up; I mean then that favorite dish of the ancient Romans, the "gallas spads or capon," or more plainly, the cock altered by castration, and in such high repute was it, that it generally graced the board of that most excellent judge of good eating, Lucullus, and if Shakspeare is to be believed, it was a tit-bit not only with Jack Falstaff, but with the Justice who is represented—"In fair round body with good capon lined." In England, at the present day, at every respectable eating-house, the first thing that greets the eye of the traveller and heads the bill of fare, is a capon, either boiled or baked. In France they are made doubly useful, not only as an article of food, but a means of production; if I may be allowed the expression, they are used as a foster-mother for raising chickens, which they do much better than the hen, owing to the large size and thick coat of feathers. The poulterers use a considerable number of them for this purpose,—the moment the hen has hatched her brood they are given to the capon, which rears them with all the care of the mother, the hen is cooped and fed until she gains her flesh and strength, and then turned out to lay and set again; in this way the poulterer is enabled to raise a large number of chickens from half the number of hens. The capon at market sells higher than any of our domestic fowls. What is the reason then in our country, where good living is so highly prized, the capon is seldom or never seen? Should you travel from Maine to New Orleans, you will probably never have this question put to you at table, "Sir, shall I help you to a fine piece of capon." I would by no means attribute this neglect of one of the finest dishes in the world to obtuseness of palate, but rather to a want of the necessary information as to the manner of performing the operation on the cock. To obviate this, I will subjoin directions, by the observance of which a man of common adroitness can make two dozen capons in an hour. Lay the chicken before you on his left side, with his head towards your right hand. Let an assistant hold him by his head and legs extended; with a sharp knife make a transverse incision of one and a half inch or more in the side just below the ribs. Insert the fore finger, and near the middle of the body, at the distance of about three quarters of an inch from the incision, near the spine will be found the testicles, which may very easily be removed by the thumb and finger; sew up the orifice and daub a little tar over it to keep off the flies. Care should be taken in cutting through the several integuments lest the viscera be wounded. The cock should be about half grown. Not one in a hundred will die if the operation be properly performed. After a fair trial both of the bacon and capon, should you relish them, I may be induced at some future time to serve you up some other dish, which I only hope may be found as agreeable to your numerous readers as was the long and learned dissertation we had some time since upon Hollow Horns. With my best wishes,

I am respectfully your ob't. serv't.

J. W. J.

From the Genesee Farmer.

DUCKS.

It is stated in a New-York newspaper, "that several of the farmers on Long Island, who raise large numbers of ducks, have had nearly their entire flocks of young ones destroyed, by a red insect named the 'Lady bug:' a *post mortem* examination led to the discovery, as, on opening the body, the bugs still living were taken out by the handful." So far as our observation has gone, insects of all kinds, with perhaps a single exception, have flourished abundantly the present season, the high temperature of June having proved as propitious to their increase as to the rapid growth of vegetation. The exception to which we have alluded, is the common striped bug, so fatal to cucumbers and squashes, of which we have not seen a single one the present season.

CONSIDERATIONS UPON THE NATURE OF THE VEGETABLES THAT HAVE COVERED THE SURFACE OF THE EARTH, AT DIFFERENT EPOCHS OF ITS FORMATION; READ BEFORE THE ACADEMY OF SCIENCES OF PARIS, ON THE 11TH SEPTEMBER, 1839, BY MONS. ADOLPHE BRONGNIART.

Translated from the French, and communicated for the Journal of Science and Arts, by R. W. Haskins,* of Buffalo, New York.

Curiosity is one of the most distinctive faculties of the human mind; one of those that most clearly mark the distance between man and the brute creation; and for this reason it may designated one of his most noble faculties, whenever directed to any end really worthy of his being.

It is this which continually excites us to extend the field of our knowledge, and to fathom the most hidden mysteries of nature, without being able to hope, for the most part, any other reward than the good which will result to all intelligent beings, in proportion as they are able to form ideas more exact upon the nature of the phenomena which surrounded them. These phenomena appear the more difficult of investigation in proportion as, by their nature and position, they are farther removed from our direct observation; and in like manner we are struck with the results to which profound researches have conducted those men who have made these investigations the object of their studies.

The invention of the telescope, by opening to our view what is passing in the elongated regions of space; and of the microscope, by revealing to us the existence of numberless beings so minute as, but for this instrument, would for ever have escaped our observation, have made, upon the human imagination, the most vivid impression.

The sciences have made such rapid advances, within late years, that no one can reasonably expect to open new views and to disclose new truths equally exciting to human curiosity as those disclosed by the telescope and the microscope; but still, the study of the soil upon which we daily tread, has become, within the last half-century, in the hands of Werner, of Cuvier, and the crowd of learned and able men who have assiduously followed these illustrious pioneers, one of the sciences the most fruitful in results, not only of high interest to the professionally learned, but well calculated vividly to interest the imagination of all persons who love to reflect upon the great phenomena of nature.

In investigating the layers which compose the superficial strata of the earth, their order of super-position, their nature, and the animal and vegetable remains which they contain, geology traces for us the history of the earth, during the long periods of time that have preceded its pre-

*Mr. Haskins prefers an orthography in some cases peculiar, and retains also certain French idioms.—Eds.

sent condition; it makes known to us the beings which have successively inhabited its surface, the revolutions that have conduced to their destruction, and those which have given birth to the mineral layers the earth contains, and the modifications to which this surface itself has been subject by reason of these revolutions; it discloses to us, in short, that all these phenomena, which have necessarily required so many centuries for their accomplishment, were prior, in point of time, to the creation of man. It conducts us alike to appreciate events, and to re-construct beings which have preceded, many thousand years, not only the most ancient historical traditions, but also the very existence of our race.

This prolonged history of the formation of the superficial strata of the earth, is constituted, like the history of nations, of periods of repose, or of tranquillity sufficiently great, at least, for the waters and the dry land of the surface to become peopled by a variety of inhabitants; and of periods of revolution, during which resistless forces have agitated this surface, elevating mountains, submerging lands previously dry, and causing ancient beds of oceans to issue from the bosom of the deep; in short, pouring over pré-existing rocks the materials for new layers which, enveloping the ruins of living beings, destroyed by these violent convulsions, have thus preserved their remains as precious monuments which now reveal to us, after so many thousand years, the nature of the ancient inhabitants of our globe, and the order in which the several races of beings have succeeded each other.

The study of the periods of these revolutions, and of those of repose, are alike of the most vivid interest: but the first are entirely the province of the geologist; while the second, on the contrary, necessarily require the light of the zoologist or the botanist; for these alone are able, by an exact comparison of the fossil remains of former beings with the corresponding parts of such as are now existent, to determine the relations which exist between the inhabitants of the globe, at various and distant epochs. It was thus Cuvier, in his admirable researches upon fossil bones, basing his investigations upon the positive data which comparative anatomy furnishes, was enabled to reconstruct the skeletons of the greater part of the animals of which the remains had then been discovered, and also to determine, with the greatest probability, their exterior forms, and their analogy to those animals with which we are now acquainted.

Botany, nothwithstanding it has long furnished fewer documents upon the ancient state of the globe, ought, nevertheless, to be equally laid under contribution, by the geologist; and it is even able to cast more light than zoology upon the state of the terrestrial surface, during the most ancient periods of its formation. Indeed, at that epoch when life first began to be manifested upon our globe, the animals were all confined to the interior of the waters, and even these presented but diminished specimens of their kinds; while a powerful vegetation, forming vast forests, covered at that early period, all such parts of the earth as were not submerged by the sea; and each succeeding period of repose has had its own peculiar vegetation, more or less varied, and in greater or less abundance, according to the circumstances which influence the development of the beings that composed it, and perhaps, also, in proportion to the duration of these periods; but almost always entirely different from those of either the preceding or succeeding epochs.

Of the different associations of vegetables which have successively inhabited our globe, there are none which so pointedly merit our attention as those which seem to have been first developed upon its surface; which appear during a long space of time to have covered with dense forests all those parts of the earth that rose above the general level of the waters, and of which the remains of successive growths, heaped one upon another, have formed our layers of coal, so deep, extensive and numerous; and in this form the remains of these primeval forests, which have preceded, by so many centuries, the existence of man, and which now supply us with fuel, in place of our more modern forests, of which the great increase of the human family is causing a rapidly augmented destruction, have become one of the principal sources of the prosperity of nations.

None can doubt that coal owes its origin to accumulated masses of vegetables, changed and modified, as probably the layers of peat in our marshes would be, if they had been overlaid by thick coverings of mineral substances, compressed under the weight of these, and subsequently exposed to an elevated temperature. If farther confirmation of this origin were necessary, it is found in the almost ligneous structure which coal sometimes presents, and in the numerous remains of plants contained in the rocks which accompany it.*

But the study of the impressions of stems, leaves, and even fruit, which are in general contained, in so great quantities, in these rocks, proves not only the vegetable origin of this substance, but even enables us to determine the nature of the vegetables of which it has been formed, and which, consequently, at the period of such formation, occupied the surface of the earth.

Among these vegetable imprints, the most frequent are those produced by the leaves of the ferns; yet these ferns of the primitive world are not those which now grow in our climates; for Europe, at this time, does not produce more than from thirty to forty species, while the same regions then nourished more than two hundred, all much more analogous to those now found between the tropicks than to those of the temperate climates.

In addition to the leaves of ferns, the same earths contain trunks, the dimensions of which render them comparable to the most gigantic trees of our forests, while their form is wholly dissimilar; and indeed all the ancient naturalists, struck with this dissimilarity, and yet desiring to find analogous productions still existent, referred them to arborescent vegetables, then imperfectly known, as the bamboos, palms, and the great cactus, sometimes designated *torch-thistle.* But a more

* The most complete and valuable collection of plates of impressions of these coal plants which is generally accessible, in this country, will be found in this Journal, vol. xxix, No. 2. This volume contains Dr. Hildreth's valuable paper upon the coal deposits of the valley of the Ohio, which he has accompanied with some thirty pages of excellent drawings of fossil remains and impressions, mostly vegetable, found in the accompanying rocks.—*Translator.*

attentive comparison of these products of the equinoctial regions with those trunks, the growth of the ancient world, suffices to dissipate all relations, which are founded only on some resemblances in the general aspect, that have been attempted to be established between them; and a more profound examination, either of these trunks or of the leaves which accompany them, readily shows that the vegetables which formed these primitive forests are not identical with any trees still found flourishing upon the earth.

The arborescent ferns which, by the elegance and magnitude of their exterior, now form one of the principal ornaments of the equatorial regions, are the only arborescent vegetables which are recognized, even in small number, among the trees of this antique vegetation.

As to the other fossil stems, remains of these primitive forests of the ancient world, it is among the most humble vegetables of our epoch that we must seek their analogues.

For instance, the calamites, which attained from four to five mètres (a little more than 13 to 16 feet) of height, and from one to two décimètres (not quite four to eight inches) of diameter, have almost a complete resemblance, in all the points of their organization, with the equiseta (horse-tails) which grow so abundantly in the marshy situations of our climates, and of which the stems, hardly as large as the finger, rarely surpass one mètre (about 39⅓ inches) in height. The calamites, then, were arborescent equiseta, a form under which these plants have wholly disappeared from the surface of the earth.

The lepidodendrons, of which the numerous species appear to have mainly constituted the forests of this ancient epoch, and which have probably contributed more than all other vegetables to the formation of coal, differ very little from our lycopodiæ. We recognize in their trunks essentially the same structure, the same mode of ramification; and in short we see inserted upon their branches leaves and fruits analogous to those of these vegetables. But, while the lycopodiæ of the present day are small plants, most frequently creeping, and similar to the great mosses, attaining very rarely one mètre (about 39⅓ inches) in height, and covered with very diminutive leaves, the lepidodendrons, preserving the same form and aspect, elevated themselves to twenty or twenty-five mètres (a little more than 65 to 82 feet,) having, at their base, near one mètre (about 39⅓ inches) of diameter, with leaves which sometimes attained to half a mètre (over 19½ inches) in length. These were, consequently, arborescent lycopodiæ, comparable, by their stature, to the largest firs, of which they enjoyed the rank, in this primitive world; forming, as these now do, immense forests, in the shade of which were developed the ferns, so numerous at that period.

How different this powerful vegetation from that which now clothes, in ever-varying tints, the surface of the earth! Magnitude, strength, and activity of growth, constituted its essential characteristicks; the smallest plants of our epoch were then represented by gigantick forms; and yet, what simplicity of organization, and what uniformity in the midst of a vegetation so enormous!

At the present day, even in those regions where nature has suffered no change at the hand of man, the eye reposes with delight upon trees which are immediately distinguishable by the diversity of their form, and the tints of their foliage; and which often support flowers or fruits of the most dissimilar colors. This variety of aspect is still more strongly illustrated by a contemplation of the diversified shrubs and plants which fringe the borders of our forests, or adorn our meadows, and of which the flowers exhibit to us almost all the tints of the prism. Finally, there result from this diversity of structure, among these plants, many varieties suited to the nourishment of man or of animals; and indeed such as are even indispensable to their existence.

The variety in the organization and aspect of the vegetables which at present cover our globe is indicated by the number of natural groups into which they are capable of being divided. These groups or natural families amount to more than two hundred and fifty, of which about two hundred belong to the class of the dicotyledons, (which consequently present the greatest variety of structure,) and thirty to that of the monocotyledons. Now the first of these classes, that is, the two hundred families which they contain, are completely wanting in our primitive flora, and seldom can we there recognise any indications of the monocotyledons.

The class which constituted, almost alone, the vegetation of this primitive world is that of the vascular cryptogamia, which at present comprehends no more than five families; almost all of which had parallels in the ancient world; such are the ferns, equiseta and lycopodiæ. These families constitute, thus to speak, the first degree of ligneous vegetation: they present, like the arborescent dicotyledons or monocotyledons, trunks more or less developed, of a solid texture, although more simple than those of these trees, and garnished with numerous leaves; but they are deprived of those reproducing organs which constitute the flowers, and they present, in place of fruit, organs much less complicated.

These plants, so simple, so little varied in their organization, and which, by their number and dimensions, rise not above a very inferior rank, in our present vegetation, constituted, in the dawn of the creation of organized beings, almost the entire vegetable kingdom, and formed forests so immense that we find not their analogy in modern times. The rigidity of the leaves of these vegetables, the absence of fleshy fruits and farinaceous seeds, would have rendered them very unfit to have served as aliment to animals: but terrestrial animals, at the time of their growth, had not yet existence; the seas alone offered numerous inhabitants; and the vegetable kingdom, at that period, maintained undivided sway over all the undeluged portions of the earth; upon which it seems to have been called to play another part, in the economy of nature.

We cannot doubt, in truth, that the immense mass of carbon accumulated in the bosom of the earth, in a state of coal, and which is the product of the destruction of those vegetables which grew at that ancient epoch, upon the surface of the globe, has been imbibed, by those vegetables, in the carbonic acid of the atmosphere—the only form under which carbon, not derived from the destruction of preëxisting, organized beings, can be absorbed by plants.

Now, a proportion, even very feeble, of carbonic acid, in the atmosphere, is generally an obstacle to the existence of animals, and particularly of the most perfect classes of them, as mammifers, and birds; while, on the contrary, this proportion is highly favorable to the growth of vegetables: and if we admit that there existed a proportion very much greater of this gas in the primitive atmosphere of our globe than the present atmosphere is found to contain, we may consider this one of the principal causes of the powerful vegetation of these ancient epochs.

This collection of vegetables, so simple, so uniform, and which would consequently have been so little fitted to furnish suitable aliment for animals of diversified structure, such as those existing at the present day, in purifying the atmosphere of the carbonic acid which it then contained in excess, would have prepared the conditions necessary to a creation more varied: and if we still wish to indulge that sentiment of pride which has caused man to assume that all in nature has been created exclusively for him, we may suppose this primitive, vegetable creation, which preceded, by so many centuries, the appearance of man upon the earth, was, in the economy of nature, designed to prepare the atmospheric conditions necessary to his existence, and at the same time to accumulate those immense masses of combustibles which his industry was in future time to apply to his necessities.

But, independently of this difference in the nature of the atmosphere, which the formation of these vast depots of fossil carbon renders extremely probable, may not the nature of the vegetables themselves, that have produced them, furnish some data upon the other physical conditions to which the surface of the earth was subjected during this period? The operations of nature now going on in different regions of the globe, may throw some light upon this question.

The study of the geographical distribution of those plants appertaining to the same families which alone composed the vegetation of the coal period, may, indeed, indicate to us the climacterick conditions and consequently the physical causes which favored the increase of stature as well as the great frequency of these vegetables; and we may conclude from these, with much probability, that the same causes determined their preponderance at that epoch.

We see for example, that the ferns, equiseta, and lycopodiæ attain a more lofty stature in proportion as their geographical position approaches the equator. Thus it is only in the hottest regions of the globe, that we find those arborescent ferns which combine with the towering and majestick mien of the palms, the elegant foliage of the ordinary ferns, and of which we have indicated the existence in the coal formations. In these same regions the equiseta and lycopodiæ attain to a stature double or triple that which the largest of these species present in temperate climates. A second condition appears to have a still more marked influence upon their preponderance, in reference to the vegetables of other families, namely, humidity and uniformity of climate; conditions which are united in the highest perfection, in the small islands situated far distant from continents.

In such islands, indeed, the extent of the surrounding oceans fixes a temperature with but slight variations, and coupled with perpetual humidity; circumstances which appear to favor, in a remarkable manner, the development and the variety of specifick forms among the ferns and the analogous plants; while, on the contrary, under the influence of the same conditions, the phenogamous plants are little varied, and are far less numerous. From these causes it results, that while on the extensive continents of the earth the vascular cryptogamick plants, such as the ferns, lycopodiæ, equiseta, &c. often form scarcely one-fiftieth of the total number of vegetables, yet in the small islands of the equatorial regions, these same plants constitute almost half, and in some cases, even two-thirds of all the vegetables which inhabit them.

The archipelagos, situated between the tropicks, such as the islands of the great Pacifick ocean, or the Antilles, are, then, the points of the globe which at the present time present vegetation the most analogous to that which existed upon the earth when the vegetable kingdom commenced, for the first time, to develop itself thereon.

Detailed examination of the vegetables which accompany the coal cannot fail, therefore, to induce the inference that at this remote epoch the surface of the earth, in the countries where are found those vast depots of fossil carbon with which we are most familiar, namely, in Europe and North America, offered the same climacterick conditions which now exist in the archipelagos of the equinoctial regions; and probably a geographical configuration little different.

When we consider the number and thickness of the layers which constitute most of the coal formations, and examine the changes that, from first to last, have taken place in the specifick forms of those vegetables of which they have been constituted, we cannot fail to see that this stupendous primitive vegetation, during a long interval, must have covered with its dense forests all parts of the globe which were at that period elevated above the sea; for all these present themselves with the same characteristicks in Europe and America; and equinoctial Asia, as well as New Holland, seem therefore to have participated, in this general uniformity of the structure of vegetables.

Nevertheless, this primitive vegetable existence promptly disappeared, to give place to a new creation, composed of beings of an organization less extraordinary than the preceding, but almost equally different from such as flourish at the present day.

To what cause can we attribute the destruction of all the plants which characterize this remarkable vegetation.

Is it due to some violent revolution of the globe? Did it arise from the gradual change of the physical conditions necessary to their existence; a change in part arising from the presence of these vegetables themselves? These questions cannot be resolved in the present state of our knowledge upon the subject.

Certain it is, however, that the deposition of the last layers of the coal formation was followed by the destruction of all the species which constituted this primitive vegetation, and particularly of those gigantic trees of peculiar structure, as the lycopodiaceæ, the ferns and the equiseta of gigantick growth; which was an essential characteristick of this primitive creation.*

After the destruction of this primitive vegetation, the vegetable kingdom appears for a long period not to have attained the same degree of development. Indeed, in the numerous layers of secondary earths which succeed the coal formations we scarcely ever find those masses of vegetable imprints, a species of natural herbariums, which, in these ancient depots of carbon, attest to us the simultaneous existence of a prodigious number of plants. Scarcely in any part of these formations do we meet with thick layers of fossil combustibles; and never are such layers often repeated, or found of such great extent as in the coal deposits. Either the vegetable kingdom at this period occupied more circumscribed portions of the surface of the earth, or its scattered individuals covered but incompletely a soil of little fertility, and of which the revolutions of the globe had not permitted them to become tranquil possessors; or, finally, the condition of the surface of the earth was not favorable to the preservation of the vegetables which then inhabited it.

Yet that long period which separated the coal from the tertiary formations, a period that was the theatre of so many physical revolutions of the globe, and which witnessed the appearance, in the waters of the deep, of gigantic reptiles, types of the fantastical organizations in which we may suppose we often recognize those monsters born of the imaginations of the poets of antiquity; this period, I say, is remarkable in the history of the vegetable kingdom, by the preponderance of two families which are lost, so to speak, in the midst of the immense variety of vegetables with which the surface of the earth is covered, at the present day, but which then predominated over all the others, by their number and their magnitude. These are the *coniferæ*, of which the fir, pine, yew and cypress furnish well known examples; and the *cycadeæ*, vegetables wholly exotick, less numerous at the present day, than at this ancient period, and which joined to the leaves and mien of the palms, the essential structure of the coniferæ. The existence of these two families, during this period, is of high importance as signalizing an intimate relation between them, by their organization; and they form the intermediate link between the vascular cryptogamia, which composed, almost alone, the primitive vegetation of the coal period, and the phanerogamick dicotyledons, strictly speaking, which constituted a majority of the vegetable kingdom, during the tertiary period.

Thus, to the vascular cryptogamia, the first degree of ligneous vegetation, succeeded the coniferæ and the cycadeæ, which held a rank more elevated in the vegetable scale; and to these last succeeded the dicotyledonous plants, which occupy the summit of that scale.

In the vegetable kingdom, as in the animal, there has been, then, a gradual improvement in the organization of the beings which have successively existed upon our earth, from the first which appeared upon its surface even to those that inhabit it at the present day.

The tertiary period, during which were deposited those earths that now form the soil of the principal capitals of Europe, as London, Paris, and Vienna, witnessed transformations, in the organick world, greater than any of those which had taken place since the destruction of the primitive vegetation.

In the animal kingdom: the creation of mammifers,* a class which all naturalists concur in placing at the summit of the animal scale, and by which nature seems to have preluded the creation of man; in the vegetable kingdom, the creation of the dicotyledons, a grand division which, by unanimous consent, botanists have always placed at the head of this kingdom, and which, by the variety of its forms and organization, by the magnitude of its leaves and the beauty of its flowers and its fruits, must, of necessity, have imprinted upon vegetation, an aspect very different from that which it had offered through all previous periods.

This class of dicotyledons, of which we are scarcely able to cite any indications at the close of the secondary, presented itself, all at once, during the tertiary period, with preponderating influence. It then, as at the present day, held dominion over other classes of the vegetable kingdom, both in reference to the number and variety of the species, as well as the magnitude of the individuals. Thus the assemblage of vegetables which inhabited our climes during the deposition of the tertiary formation, which enveloped their ruins in its sedimentary layers, were intimately allied to the mass of our present vegetation, and more particularly to the flora of the temperate regions of Europe and America. The soil of these countries was covered then, as at present, with pines, firs, culms, poplars, birches, elms, walnuts, maples, and other trees almost identical with those which still flourish in our climates.

And yet, not only do we not recognize any indications of those singular vegetables which characterized the primitive forests of the coal period, but we rarely encounter, there, even fragments of plants analogous to those which now vegetate between the tropicks.

We do not, however, necessarily infer that the same vegetable forms have been perpetuated from this epoch, still very ancient, (since it preceded the existence of man,) to the present day. No: very sensible differences almost always distinguish these inhabitants of our globe, very recent, geologically, but exceedingly ancient, chronologically, from our cotemporaneous vegetables to which they seem most nearly allied; and the existence in these same earths, in the north of France, of palms, very different from those which still vegetate upon the borders of the Mediterranean, and of a small

* We find, it is true, in some parts of the secondary formations, a small number of arborescent ferns and of the gigantick equiseta; but yet of a stature much less considerable than those of the coal formations; nor do we discover, there, any trace of the arborescent lycopodiaceæ analogous to the lepidodendrons.—*Author's note.*

* In placing the first appearance of mammifers at the epoch of the tertiary formation, I do not include the fact, unequalled elsewhere, of the fossil mammifers of Stonesfield; a case which forms an exception to all former experience, and which cannot be detailed in so limited an essay.—*Author's note.*

For drawings and brief descriptions of these fossils, which occurred in *oolite*, see Lyell's Geology, American edition, Vol. I, pp. 151-5.—*Translator.*

number of other plants which appertain to families now limited to the more torrid regions, seem to indicate that at this epoch central Europe enjoyed a temperature more elevated than at present; which, besides, accords very well with what we may deduce from the presence, in the same formations, and the same countries, of elephants, rhinoceroses and hippopotami, animals which are now rarely found to range beyond the tropicks.

What an astonishing contrast between the aspect of nature during modern geological periods, and that which she offered when the primitive vegetation covered the surface of the globe!

Indeed, at the periods in question of the geological history of the world, the earth had already assumed, in great part, at least, the form which it presents at the present day; continents very extended, and mountains greatly elevated, fixed and determined varied climates, and thus favored diversity of beings. In this way, in countries of little extent, the vegetable kingdom offered us plants equally as diversified, one from another, as those found growing at the present day.

To the coniferæ, with their narrow durable leaves of sombre green, were joined birches, poplars, walnuts, and maples, with broad leaves of a more lively tint; and in the shade of these trees, on the borders of waters or upon their surface flourished herbaceous plants analogous to those which at present embellish our fields by the diversity of their forms and colours, and the variety of which renders them suitable to satisfy the different tastes of an infinity of animals, of all classes.

The forests of the ancient world, like those of our epoch, served, indeed, as a refuge for a vast number of animals, more or less analogous to those which still inhabit our globe. Thus elephants, rhinoceroses, wild boars, bears, lions and stags, of all forms and of all statures, have successively inhabited them; while birds, reptiles, and numerous insects, complete this map of nature, as she presented herself, upon such parts of the earth as were elevated above the level of the oceans; the whole forming a scene equally beautiful and equally varied as that which is still witnessed upon the emerged portions of our globe.

On the contrary, at the dawn of the creation of organized beings, the terrestrial surface, divided, without doubt, into an infinity of islands, low, and with a climate almost uniform, was, it is true, covered with immense vegetables; but these trees, differing little from each other in their aspect, and the tint of their foliage; deprived of flowers and those fruits with brilliant colors which so highly adorn many of our large trees, must have imprinted, upon that vegetation, a monotony not interrupted even by those small herbaceous plants that, by the elegance of their flowers, constitute the ornament of our groves.

Add to this, that neither mammifer, or bird, nor any animal, in short, was present to enliven these dense forests, and we may be able to form a very just idea of this primitive nature; sombre, cheerless and silent, but at the same time so imposing by its grandeur, and by the space which it has been called to fill in the history of the globe.

Such, gentlemen, is a rude outline of the great revolutions of terrestrial vegetation, as the researches made upon this subject, within the last thirty years, have enabled us to trace them. Each day will doubtless add new traits to these details; but recent discoveries, by confirming the results at which we had previously arrived, seem to assure us that this general delineation will not experience great changes when, thanks to the materials that are being collected on all sides for this object, we shall be enabled to transform this rough draught into a picture more finished and complete.

SIXTH ANNUAL REPORT OF THE PRESIDENT AND DIRECTORS OF THE PORTSMOUTH AND ROANOKE RAILROAD.

In submitting to the stockholders of the Portsmouth and Roanoke railroad a report of the progress, business and prospects of the company during the past year, respectfully represent:

That the subscription of $50,000, authorized by law and accepted by your last general meeting, was made and the money paid by the board of public works, in August last, which sum, it was believed, would enable this board, besides satisfying all pressing demands, to have completed the warehouse and wharf which had been commenced in Portsmouth; this would have been effected, but for the melancholy accident which happened about this period. A train carrying a number of persons residing along the line of the road, who had for recreation merely visited the towns, on their return were met by a train bringing a load of lumber, a short distance beyond Suffolk, at the only point on the road where a meeting would have been considered dangerous. As both were descending, and not perceived by either until too late to arrest their progress, a collision ensued most disastrous in its consequences. Demands for payment increased: these and the expense in replacing the coaches destroyed, absorbed all our funds, and for some time the revenue was insufficient to meet the current expenses. When business revived, and the Weldon bridge was nearly prepared for use, two additional engines were procured, which unfortunately proved too heavy for our road, a portion of which was discovered to be decaying. Another accident not less fatal in its consequences than the former, occurred a few days after we had succeeded in crossing the Roanoke, when our prospects seemed most promising. This was occasioned by the elevation of the end of an iron rail perceived too late to be prevented. By DOUBLING it threw the engine off the track, which suddenly checking the progress of the train, caused a dreadful crush of all the coaches which were next the engine. Until that fatal event, this position was believed the least liable to injury, in case of accident, as cars in the rear had several times run off, without injury to the coaches in front of them. The practice of placing the coaches in rear of the burthen cars has from that day been adopted by us, and, we are informed, other roads have made the same change after hearing of our misfortune.

This second dreadful calamity, added to the state of dilapidation in which that portion of the road between Portsmouth and Suffolk was found to be, threatened a total suspension of all the business of the road. But by increased exertion such repairs have been effected, and by improvements in the condition and management of the engines, and regularity in the running, confidence seems in a great measure restored, and the travel has so much increased as to justify the opinion heretofore expressed that few roads in our country have a better prospect of ultimate success.

Among the errors into which we have fallen, it is believed that the effort to establish and carry on an extensive manufacture of machinery has proved the most expensive, though in the infancy of our establishment the difficulty and delay met with in promptly procuring necessary articles or repairs seemed to render such an establishment indispensable. Now when the number of such factories has greatly increased, conducted by workmen for their own account, it is believed that a small part of the force, heretofore deemed necessary, will be required, consequently reducing greatly these expenditures. Considerable loss has also been sustained by being compelled, in consequence of a mail contract and the delay in finishing Weldon bridge, to purchase stages and horses, which we had contracted to have furnished up to the period when it was supposed they would be no longer required. That period having arrived, being unable to renew or extend our contract, and the bridge still unfinished, the purchase was indispensable.

Application was made to our late legislature for a loan, on a pledge of the stock and profits of the company. The terms on which it has been authorized, require the consent of the stockholders; the law is submitted for your consideration. It may be proper to remark that a reliance on that aid has enabled us to procure a credit, without which it would have been impossible to have continued the operations of the road.

By agreement with the Wilmington company we are permitted to use their road to Halifax, and when finished (which it is expected will be about the first of July next,) to continue our run to Enfield, about ten miles farther south, by which their stage route will be much shortened. Mutual interest will secure the continuance of that good feeling, which has ever prevailed between these companies.

An agreement has also been entered into with the Maryland and Virginia steamboat company, which, while it affords increased expedition and comfort to travellers, cannot fail greatly to advance the interest of both companies.

With the aid relied on from the state, the company will be relieved from existing debts, be enabled to finish the wharf and warehouse so much needed for the accommodation of the business of the road, and to procure necessary engines and coaches, and then by means of the connexions already secured, we feel fully justified in our expression of confidence in the value of this enterprise.

The reports of the treasurer and general agent are herewith submitted.

By order of the board.

ARTHUR EMMERSON, President.

Office of the Portsmouth and Roanoke Railroad Company.

To the President and Directors of the Portsmouth and Roanoke Railroad Company:

Gentlemen:—Although from personal observation you may be presumed to be acquainted with the condition of the work under your control which has been committed to my management, it may be considered my duty according to usage to review the operations upon the road since the affairs of the company were confided to me.

By reference to the 5th annual report of the president and directors, it will be seen that the road was opened to Garysburg in August, 1836. The tardy progress of the remainder of the work, comprising the superintendence from Garysburg, to the Roanoke river, the bridge across the Roanoke, and the road and fixtures at Weldon, rendering my personal attention only occasionally necessary, I voluntarily relinquished one half of my annual salary in October, 1836, still however retaining entire charge of the transportation until May, 1837, when, agreeably to some general regulations of the stockholders, the duties of general agent of transportation devolved on the president of the company, and I confined myself entirely to the completion of the road, which was effected in November, that is, on the 27th of November last, the bridge over the Roanoke was so far completed as to allow the passage of the cars, which commenced on that day running regularly to Weldon.

On the 1st January, 1838, I again resumed the charge of the transportation department by a resolution of the board appointing me the "general agent and superintendent of the affairs of the company." I found the road very much injured by the use of two heavy engines which had been most ill-advisably placed upon it. Between Portsmouth and Suffolk, where the rails had undergone some decay, the road was entirely broken down, and almost impassable. Between Suffolk and Weldon, although much of the iron was broken and many of the rails crushed, this portion of the road was not so materially injured. My attention was immediately directed to the repairs of the road, and a large force was employed, which soon put it in a condition that has, I believe, given general satisfaction to the public and to all concerned. The engines were also put in repair; and without going into details, let it suffice to say, that, since the 10th of January, the cars have been running with a regularity and speed unsurpassed by any other road in the country. And, as I observed in my report to the board in May last, nothing is now wanting but an administration of the affairs of the company upon the system which has been adopted. The simplicity of a railroad with its embankments, excavation, bridges, and iron-capped superstructure, and the great ease with which high velocities are attained, and immense burdens transported, are too apt to beguile those unacquainted with such matters into the belief that all is accomplished when the wheels are put in motion, when in fact the work is but just begun. Besides the many heavy losses which companies have sustained, the whole railway system has well nigh been brought into disrepute by so fallacious an opinion. A reference to my printed reports, but more especially my communications on file in the office of the company, will show the great anxiety I have felt, from the very commencement of your improvement, to leave the management of your road in competent hands.

In my report of 1836, nearly twelve months before the completion of the railroad, in my remarks under the head of transportation, I observe, in relation to the agent, that the various and complicated duties to be performed by such an officer after the completion of the road—including the enforcement of established regulations, the institution of such rules as may be found necessary for the well ordering and conducting of the affairs of the company, the disbursements, repairs of the road, and frequently important negotiations—indicate the necessity of filling the appointment with one whose thorough knowledge of business, enlarged and liberal views, qualify him for its duties. And again I observe the connexion of this with other improvements, with steamboats and stage lines, and the collisions and differences which cannot fail to arise, attach to your agent a responsibility of no ordinary character, and require the exercise of great firmness, with a full and comprehensive understanding of the rights and interests of the company. And in my last annual report, after adverting to the many advantages resulting from a connexion with other improvements in progess, and the great addition thereby to your income, I say that even with such brilliant prospects, the road cannot succeed without the most skilful and prudent management of its general operations, and the strictest economy in the application of its resources; and this can only be insured by able and zealous officers, and I now take the occasion to repeat that no advantages, nor can any combination of circumstances counteract the effects of bad management, and I reiterate that with prudent and skilful management, your road cannot fail to be productive.

The repairs of the road since the 1st of January, notwithstanding the many disadvantages under which they have been made in the short days of the most inclement winter months, and the advantage always taken of urgent necessity, such as existed in the crippled state of the road between Portsmouth and Suffolk, have only cost $4762 35: of this $2711 17 have been expended between Portsmouth and Suffolk, and the remainder $2051 16, between Suffolk and Weldon. There are now engaged in the repairs of the road, five overseers and thirty hands. It is necessary, however, and directions have accordingly been given to increase this force to about 60 hands for a few months, with the view of removing the earth from the rails which was beaten down against them from the horse-path by the rains of the past season, and the weeds and grass which were permitted to decay and lodge around the timbers, and which are now springing up with renewed vigor, and, if not soon removed, will totally destroy the road.

All experience has proved the advantage and the economy of keeping on hand a supply of timber. Contracts are made cheaper when it is known the demand is not pressing, and by being seasoned before used, the durability is much increased. I have accordingly contracted for about three hundred thousand feet of rails and thirty thousand sills, to be delivered in the course of the year. This amount will be sufficient for the present, and will leave a good supply on hand for the ensuing year. I have also given directions for the erection of suitable sheds for the preservation of the timber, and for buildings contiguous to them, for the accommodation of the overseers, and hands engaged in the repair of the road, who on rainy days, can be occupied in dressing and preserving the timber for use.

The road between Portsmouth and Suffolk was completed in the summer of 1834. The superstructure consists of heart pine rails 7 by 5 inches, keyed into oak, pine, chinquepin, sassafras, and cypress sills, 8 feet long and from 10 to 14 inches in diameter, flatted on one side and placed 4 feet apart. The iron on this portion of the road is $\frac{5}{8}$ by $2\frac{1}{4}$ inches. Between Suffolk and Weldon, the superstructure is on the same plan as the above. The iron is $\frac{1}{2}$ by 2 inches; the rails are 5 by 9 inches, keyed into sills of oak not less than 12 inches in diameter, and placed 5 feet apart. The timbers were laid at different periods between the summer of 1834 and the winter of 1836. The repairs on this portion of the road, during the present year, will comprise the renewal of about one-sixth of the timbers between Suffolk and Blackwater, and but very few for the remainder. Between Portsmouth and Suffolk it will be necessary to replace at least three-fourths of the timbers. The bridges will require very partial repairs. But few of them need any. Whenever it is necessary to renew any portion of the road entirely, I would advise the adoption of the superstructure recommended by me for the Roanoke, Danville and Junction Railroad, and which is now being put down on the Wilmington and Raleigh Railroad. By this plan, the rails are fastened on the tops of the sills by trenails and knees, instead of being keyed as they ordinarily are into the sills. This renders it necessary that the sills should be *square* and *entirely of heart*—and indeed the necessity of the last requisite is no less important upon any plan, for the sap not only rots in the course of a few months, but promotes the rapid decay of any timbers in contact with it, and therefore the contracts herein reported are for heart sills.

I have stated that the engines are now and have been running with great regularity. The time consumed in the daily trips over the road, (including delays) is $6\frac{1}{2}$ hours. Deducting detentions for wood and water, it gives for the travelling time $5\frac{1}{2}$ hours, being a speed at the rate of 16 miles per hour. This statement, compared with the state of things which existed just prior to my taking charge of the road, (as for example, the cars were from $2\frac{1}{2}$ to 3 hours in running between Portsmouth and Suffolk, a distance of $17\frac{1}{2}$ miles,) gives an idea at once of the improvement in the condition of the road. It is now in good repair; but to keep it so, will require the most constant attention. I would hereby remark, while on the subject, that the arrangements which have been made, contemplate the most thorough repairs in the course of the present year. The interests of the company, and their duty to the public, require that the road should be kept in the best possible order.

I have next to state the condition of the motive-power and vehicles of transportation. When I took charge of the road, the two heavy engines, before mentioned as having done so much damage to the road, were condemned by me, on account of their weight, (though in other respects very superior machines,) and under an order of the board to sell them, a contract has been made with the maker to exchange them for lighter engines. Of the remaining five engines, there was but one in running order—the other four had been improperly condemned by the late foreman of the shops, as will appear by the annexed return which exhibits the performance of the locomotives, and the cost of the repairs for the months of January, February and March, during which period as well as during the month of April, there have been three and often four engines on the route daily. There are now 70 cars and 6 coaches on the road. Two eight-wheeled coaches have been contracted for. One may be expected in a few days, and the other in the course of a few months. I have also contracted for 40 cars, to be delivered in the course of this year.

The agents of the company are all acting under the written regulations which were placed in their hands when the road was first opened for transportation, (but which had been neglected,) and not the slightest accident has occurred since the 1st January. With the view to additional security and to guard against any delay that might be caused by the machinery of the passenger train giving way, the freight is transported by a separate engine following that which conveys the passengers, and keeping just in sight. The engines are all provided with alarm bells, and the train agent is directed to take his seat on the top of the baggage car, where he can overlook the train, and keep always in his hand, a rope attached to the bell on the engine, and besides the break which he himself can apply, the trainmen are kept constantly at the breaks while the train is in motion—and indeed every precaution dictated by experience here as well as elsewhere, has been taken to guard against accident, which, should it occur, (provided the present regulations are strictly enforced,) will be beyond the power of human foresight to control or guard against. By referring to the annexed table, it will be seen that the amount of the receipts during the past year, is $49,371 11. For the months of January, February and March, the receipts, are $11,479 43, and the expenditures on account of the repairs of locomotives, cars, coaches, the repairs of the road, and the salaries of agents and superintendents is $14,856 86—every item of which, as will readily appear from what I have said, must exceed by far the average expenses of the road. By reference to the pay rolls filed in the treasurer's office, it will appear that the expenditures in the shops for the month of March, amount to very little more than one-half of the expenses for the month of January. In the latter, the amount is $1,867 41, making a saving of $916 79.

Supposing the fiscal year to end on the 30th April, the accounts of the company for the ensuing year may be stated as nearly as may be as follows:

Received.

On loan from the state,	$150,000
For gross amount of transportation,	80,000
	$230,000

Disbursed.

Paid the outstanding debts,	$115,000
Charges on transportation including repairs to the road,	50,000
Interest on $150,000 at 5 per cent.,	7,500
For timber on hand, and sheds,	20,000
For cars and coaches,	14,000
For warehouse in Portsmouth,	10,000
For contingencies,	3,500
Cash on hand,	10,000
	$230,000

It will be observed that, in the foregoing estimates, I have anticipated an increase in the receipts of the road for the ensuing year of about $30,000. When it is considered that the receipts have not fallen off during the past, by far the most eventful year in the history of our country—unparalleled in commercial distress, and the prostration of every branch of industry, paralyzing alike the most gigantic national enterprises, and the efforts of the wealthiest as well as the most humble individual. In retrospect of these distresses which have pervaded our land from one extremity to the other, and the many untoward circumstances, which have tended to embarrass the company, we have shown that the road has prospered—may we not therefore anticipate an increase in the receipts from the awakening energies of the country?

In the discharge of the arduous and responsible duties which have devolved on me during the last four months, I have been most efficiently aided by Capt. Charles Dimmock, whom I would beg leave to recommend as an able and efficient officer, every way worthy of trust and confidence.

In conclusion, gentlemen, I have to state that I now resign the office of "general agent and superintendent of the affairs of the company," so flatteringly bestowed on me by a unanimous resolution of your board of the 1st of January last.

I am, gentlemen, very respectfully, your obedient servant,

WALTER GWYNN, *Civil Engineer.*
Portsmouth, 1st *May*, 1838.

Report of the Annual Committee.

The annual committee appointed at the last general meeting in July, have, as far as practicable, performed the several duties required of them, by "examining into the condition of the road," "inquiring into the management of the same, and the manner in which the books are kept," and by recommending to the directory, as far as they were competent, such measures as in their opinion would tend to promote the permanence and value of the road."

They entered upon their duty about the middle of November, by visiting and viewing the entire line of the road. The first eighteen or twenty miles of it commencing at Portsmouth, they found to be in a decaying and disordered condition. That portion of it, especially, which passes through the Dismal Swamp, a few miles east of Suffolk, was in a state which required immediate and extensive repairs. The balance of the line, including excavations, embankments and bridges, was in good order, with the exception of the iron on the rails, the ends of which were, in many places, so loose as to spring above the level of the ways.

The inquiries and examination of your committee into the general management and success of the road, at the period above alluded to, were far from affording a gratifying or satisfactory result. The motive power was inefficient, the water stations at several important points, were deficient of water, and a want of attention at these important auxiliaries to the proposed and successful management of a railroad, was manifest; the trains were delayed on the line, and the detention from this cause was such as to produce so much irregularity in the time of their arrival, at either end of the road, that the complaints of disappointed passengers, were loud and frequent. This state of things continued with some exceptions, until January, when a more efficient system for the improvement, repair and management of the road was adopted.

Your committee made a second tour of examination on the road on the 24th and 25th of last month, April, and found the aspect of things entirely changed. The repairs of the road since their first visit, had been prosecuted with energy, and to the extent necessary to the security and success of the line. The road is now in good order. Measures have been adopted to secure, at all times, a plentiful supply of wood and water, by the improvement of old water stations and the establishment of new ones. The motive power of the road, though not equal to all the purposes of transportation, is more efficiently applied, and the passenger trains travel with speed and certainty, and arrive with punctuality.

Your committee have made a thorough investigation of the books of the treasurer. They have been kept with an accuracy which does credit to that officer. Every item of expenditure is sustained by the proper vouchers, and the arrangement of his books and accounts is such as to present, at a glance, a faithful exhibit of the fiscal affairs of the company. The books exhibit the receipts and disbursements as follows:

Receipts from railroad for transportation, - - - - - -	$50,336 64
All other sources, - - - -	80,075 35
	$130,411 99

Expended.

The payment of debts,	$36,669 35
The excavation, embankment and other purposes of road,	93,098 98
Balance in hand of treasurer,	643 66
	$130,411 99

Respectfully submitted,

SAMUEL WATTS, *Chairman.*

From the Mining Journal.

ASTONISHING FACTS RELATIVE TO A FORMER ORGANIC WORLD.

"Dr. Buckland now proceeds to the most important and popular branch of his subject—to give a description of the most interesting fossil organic remains, and to show that the extinct species of plants and animals which formerly occupied our planet, display, even in their fragments and relics, the same marks of wisdom and design which have been universally recognized in the existing species of organized beings.

"After giving some account of the supposed cases of fossil human bones, and establishing the remarkable fact of the 'total absence of any vestiges of the human species throughout the entire series of geological formations,' our author passes to the general history of fossil organic remains:—

"'It is marvellous that mankind should have gone on for so many centuries in ignorance of the fact, which is now so fully demonstrated, that no small part of the present surface of the earth is derived from the remains of animals that constituted the population of ancient seas. Many extensive plains and massive mountains, form, as it were, the great charnel-houses of preceding generations, in which the petrified exuviæ of extinct races of animals and vegetables are piled into stupendous monuments of the operations of life and death, during almost immeasurable periods of past time. "At the sight of a spectacle," says Cuvier, "so imposing, so terrible as that of the wreck of animal life, forming almost the entire soil on which we tread, it is difficult to restrain the imagination from hazarding some conjectures as to the cause by which such great effects have been produced." The deeper we descend into the strata of the earth, the higher do we ascend into the archæological history of past ages of creation. We find successive stages marked by varying forms of animal and vegetable life, and these generally differ more and more widely from existing species as we go further downwards into the receptacles of the wreck of more ancient creations. * * * *

'Besides the more obvious remains of testacea and of larger animals, minute examination discloses, occasionally, prodigious accumulations of microscopic shells that surprise us no less by their abundance than their extreme minuteness; the mode in which they are sometimes crowded together may be estimated from the fact that Soldani collected from less than an ounce and a half of stone, found in the hills of Casciana, in Tuscany, 10,454 microscopic chambered shells. * * * Of several species of these shells, four or five hundred weigh but a single grain; of one species he calculates that a thousand individuals would scarcely weigh one grain.'

"Extraordinary as these phenomena must appear, the recent discoveries of Ehrenberg, made since the publication of Dr. Buckland's work, are still more marvellous and instructive. This eminent naturalist, whose discoveries respecting the existing infusorial animals we have already noticed, has discovered fossil *animalcules*, or infusorial organic remains; and not only has he discovered their existence by the microscope, but he has found that they form extensive strata of tripoli, or poleschiefer (polishing slate,) at Franzenbad, in Bohemia—a substance supposed to have been formed from sediments of fine volcanic ashes in quiet waters. These animals belong to the genus Bacillaria, and inhabit silicious shells, the accumulation of which form the strata of polishing slate. The size of a single individual of these animalcules is about 1.288th of a line, or the 3400th part of an inch. In the the polishing slate from Bilin, in which there seems no extraneous matter, and no vacuities, a cubic line contains, in round numbers, 23,000,000 of these animals, and a cubic inch 41,000,000,000 of them. The weight of a cubic inch of the tripoli which contains them is 270 grains. Hence there are 187,000,000 of these animalcules in a single grain; or the silicious coat of one of these animals is the 18,000,000th part of a grain!

"Since this strange discovery was made, Mr. Ehrenberg has detected the same fossil animals in the semiopal, which is found along with the polishing slate in the tertiary strata of Bilin, in the chalk flints, and even in the semiopal or noble opal of the porphyritic rocks. What a singular application does this fact exhibit of the remains of the ancient world! While our habitations are sometimes built of the solid aggregate of millions of microscopic shells—while, as we have seen, our apartments are heated and lighted with the wreck of mighty forests that covered the primeval valleys—the chaplet of beauty shines with the very sepulchres in which millions of animals are entombed! Thus has death become the hand-maid and the ornament of life. Would that it were also its instructer and guide!"—*Ed. Review.*

THE SPRING-WHEAT HUMBUG.

To the Editor of the Farmers' Register.

Back river, Elizabeth-city county, July, 1838.

I have just read with much pleasure, and probably profit, your remarks in your Register of April, 1838, (just borrowed,) upon "Agricultural Hobbies and Humbugs;" and although I am not much pleased with the terms, so far as they depend upon the beauties of style, yet they force upon me that which Blair himself could not more convincingly have done, with all his beauties of composition; and, whilst I might have been pleased with his sounds, without conviction, your number has at least had the benefit of inducing me to the belief, that we will ride our hobbies, and so long as we do so, we are ever in the road to be humbugged. Man has always been, from the days of Adam up to the present time, the mere creature of fancy, and I believe always will be so, place him where you will; and hence his liability to be always taken in with any thing new, or which has the appearance of being so. I believe that we shall always be in search of the "philosopher's stone;" and although satisfied of the fruitlessness of the search, yet, but attack our fancy, and we immediately let loose the reins—our reason becomes blinded—and, before our career of fancy is fully over, we are not bad representatives of Phaeton, in his career of rashness. We are always too ready to believe, at least to credit, all such statements as may be sounded in the gazettes or papers of the day, particularly when they shall be blazoned forth by a few remarks from our worthy editors, who are all men of the people, ever on the alert, placed high on the watch-tower, to sound the alarm; and when, instead of the alarum bell, they are sounding to us news of glad-tidings, how ready are we to believe all their statements, and particularly so, if an editorial commendation backs them. This though is not very remarkable; because the farmer or agriculturist, relying much upon facts, yet is very credulous, and is apt to believe that most of the statements which reach him, whether communicated in the pamphlets or papers of the day, or in any other way, so far as they are introductory to any new variety in grain, or any thing else in his line of business, are true. For he, poor simple man, never once thinks that all these great products in corn, wheat, &c. sounded so repeatedly and invitingly to his ears, in many various ways, are for effect; and being honest himself, believes all others so, and hence his liability to imposition.

Such then being the state of the case, let us bring into review one or two instances where this too ready belief has led some of us into error; and I, for one, having fallen into it, take at least this mode of endeavoring, through you, to guard others against it. And although I by no means admit that there is error in the substitution of the twin, or prolific, or Baden corn, (having succeeded in making better crops of that than of any other of the large varieties of white corn,) for the large corn, I agree with you perfectly so far as the Italian spring-wheat is concerned; which, upon this second year's trial, I consider almost an entire abortion. I purchased, in the winter of 1837, of Mr. Hathaway, of Troy, New York, a barrel of the Italian spring-wheat, said to contain 3½ bushels, although, from some cause or other, I do not believe that there could have been in the barrel more than 3 bushels. The barrel was of the large size of flour barrels, and it wanted at least 3 pecks, if not a bushel, of being full; and with this a large proportion of the grains therein were oats—I think at least half a bushel. To one of my friends I parted with a half bushel, (oats intermixed,) and to another a gallon, in the same condition; the remainder I kept and sowed. I picked the oats out of the wheat, before seeding, clean by the hand, and obtained a peck and a half; the remaining part, being wheat, say two bushels, I sowed, at least a part of it, upon very rich land—a chocolate mould, high and light for our section of the country. The richest part was drilled in about three-feet drills or rows. This received, in the course of the spring, two workings with the cultivator or hoe. The other, upon land not manured, was sown broad-cast, in beds 5½ feet wide, and divided only by a narrow cart-road of about ten feet; the land nearly of the same description, with the exception of the difference made by manure. The growth of the drilled wheat was very fine; but the rust attacked it badly. The growth of the wheat not drilled was about as good as the fall or winter-wheat upon our fields in general. But this was perfectly clear of rust; in fact, I could perceive no injury to its growth from any cause. The wheat, both drilled and broad-cast, was seeded between the 5th and 10th of April. Its promise, with the exception of the rusted part, answered my most sanguine expectations; and this appearance held good until its change for maturity. I then discovered that climate, or some other cause, had its effect. The grain had all the appearance of wheat badly rusted, or injured from scab or blast; and I should have attributed its shrivelled state to the rust, but as much the larger portion of the grain seeded had no appearance of rust or any other disease, (I drilled only a gallon,) in its stalk, whilst growing, and as the grain in that part which had no rust, was *no better*, in any way, than the drilled, which had the rust, I could not account for it, and have not endeavoured to do so, further than the belief that climate had its effect. To cut short, I reaped it, and stacked: and in February last I got it out, and cleaned 25 bushels. This product from wheat, seeded as late, although the grain was indifferent, I thought a good one, and believed that this year I could make it turn out much better, provided it kept clear of rust, scab, &c., which I was induced to believe would be the case by earlier seeding. I parted with 8 bushels of the wheat, and seeded the balance, 17 bushels, to about ten acres of land, this year, 1838. Two bushels were sown in January, and the balance in March, from the 20th. It is reaped and in stacks, and I do not believe that I shall get over 50 or 60 bushels of wheat from the whole 17 seeded. It not only was attacked by the rust, but had also scab or blast, and the grain is so light that I am apprehensive that one-third of it will be blown away by the fan. There was a considerable difference in the growth of the January from the March wheat. The January growth was very fine, but the other *so light* and indifferent, that the scythe, as it passed through it, beat down a large proportion of it. I have selected two parcels of the best of the growth of each seeding, and herewith enclose them for your inspection. I discover that the winter frosts killed fully one-half of what I seeded, probably more. The same ten acres would have yielded me this year 150 or 200 bushels of the fall or winter-wheat, (golden straw, such as we seed.) You can readily perceive the loss. I am done with it and all other untried grains, at least so far as untried in our climate. I shall wait to see the experiment made by others in my vicinity, so that I can "see it, feel it, handle it." Should you ever come in this part of our state again, it will afford me much pleasure to see you; not only as an old acquaintance, but that you may set me to rights in some of my odd notions. With sentiments of the highest respect, I remain yours, &c.

P. S. I have made no corrections in this communication, as it is for you alone.

[The foregoing communication was signed by the name of the writer, (and a very responsible name it is); but the postscript placed us in doubt, whether to be directed by its purport, and to suppose this letter, (written, as it is, wholly on agricultural subjects of public interest, and superscribed with our address, as "Editor of the Farmers' Register,") was intended merely for our individual inspection and benefit—or, judging from every thing but the postscript, that it was designed as a communication to the Farmers' Register. With considerable hesitation, because of our unwillingness to place any correspondent in a position which he does not desire to occupy, we have decided on a middle course; that is, to publish the letter, but suppress the signature, which we never presume to use, without the writer's consent, expressed or implied.

Our correspondent (like several others) has drawn from our cautions against novelties which *may* (and usually, in the end, *do*) prove to be humbugs, an inference very different from our intention, and from the expressed words, as well as the general context, of our remarks. So far from advising to not *try* things newly recommended as great improvements or probable benefits to agriculture, we urged then, as we would now, the contrary. Every plausible suggestion of a supposed or asserted improvement, or new source of profit, should be submitted, fairly, to the test of experiment. But, at first, *merely of experiment*, and on a scale so small as not to cause much loss, in the very probable event of disappointment. And in deciding whether the recommendation of any new thing deserve this respect, we should have due regard, not only to the apparent reasonableness of the recommendation, but also to the fact, whether the person recommending is, or is not, a deeply interested salesman of the article in question.

Further—we would pronounce it not only bad policy for self-interest, but a failure in a moral obligation, for a farmer to wait always for his neighbors to incur the risk of failure in new experiments, and never to join in bearing some share of the cost, until others had borne that risk, and proved the benefit, by the *visible* and *tangible* profits resulting. If all were to adopt such a rule of conduct, (as is done, in fact, by the far greater number,) then, indeed, all future agricultural improvement would be hopeless.

Our correspondent has also mistaken us as denouncing the Maryland twin-corn as being inferior, in *all cases and situations*. Not so, by any means. It may well be, and doubtless is, (and so of any other variety,) the most prolific, under some particular circumstances. But we meant to oppose the popular error—that this, or any other supposed grain, can be most productive in *all*, or in many different soils and climates; and to deny the truth of the *principle* of procuring more productive kinds of grain, by the process of selecting for seed the plants which bear the greatest number of ears, or ears with the greatest number of grains, or of grains of certain form and largest size, &c.

As to spring-wheat, we have had but one opinion of its value since the commencement of its culture in this country; and we cannot understand how an opposite opinion could have been held by any person who had read and attended to the European accounts of this crop. This unfavorable opinion, so contrary to that which has been disseminated so extensively in this country, (for the profit of the northern tribe of Hathaways,) has been frequently exposed in the Farmers' Register; and if our correspondent had been prepared to profit by our advice, he would have avoided his heavy loss, by borrowing and reading the numbers of the Farmers' Register, some years earlier than he has done.

Of the two specimens of grain sent, that sown in January, though small, is full and well made. The grain from the March sowing is badly filled, and very inferior in quality. And here an observation should be made, which perhaps escaped our correspondent. It is, that his *partial success*, in the early-sown crop, was obtained by a wide deviation from the practice proposed, and a total surrender of the advantage expected from spring-wheat, to be found by sowing *after winter is over*, and the danger of winter-killing passed. Wheat sown in January, should, in fact, be considered not as spring, but as ordinary or winter-wheat. Much wheat, every season, (though without excuse,) is sown in December, and often does not sprout sooner than it would if sown a month later. But the difficulty, alone, of sowing a crop of wheat in the usually severe weather of January, would be a sufficient objection to any kind requiring such a time for sowing; which, however, is not the case with any kind.

Since writing the above, we have seen an extract from a Staunton paper, which states that the trials of spring-wheat, in that part of the country, have had very favorable results; and, thereupon, the more full use of that grain is strongly urged. We have here another example of the general fact of the readiness of farmers to be gulled, and the facility with which error is propagated, and fraud succeeds—and the difficulty with which truth is permitted to operate, to guard against either. Probably the experimenters near Staunton are now at that stage of the trial in which our correspondent was last year, and, therefore, are honestly of opinion that, *if due allowance is made for every supposed cause of diminution*, the crop is really promising. Or, perhaps, some who have paid three or four dollars a bushel for their seed, are desirous to make the crop sell as well, and to come in for a little of such large profits as Mr. Hathaway seems to have realized.]

From the Gardener's Magazine.

REMARKS ON THE PROPAGATION OF THE DAHLIA.

Every cultivator of the dahlia is aware of the facility with which it is propagated by cuttings of the young shoots, plunged in a little bottom heat. Indeed, from a single root, under proper treatment, several dozens of young plants may be raised in a short space of time. Consequently, this method is universally adopted by nurserymen; they annually requiring a large stock of young plants for sale; and by individuals anxious to propagate extensively a new variety. But it ought not to be practised by amateurs or others, anxious to obtain fine perfect flowers for exhibition or otherwise. I speak advisedly, and from experience, when I assert, that plants raised from cuttings do not produce equally perfect flowers, in regard to size, form, and fulness, with those produced by plants grown from division of the tubers, the old method of propagating the dahlia. It has been said that plants raised from cuttings flower more abundantly than those raised by division; but to this I am not prepared to subscribe.

Physiological botany readily accounts for the different results of the two methods. The starch or feculent matter, stored in the roots, is intended by nature for the nutrition of the annual shoots, not only until the tubers have formed, at the commencement of the vegetating season, the spongioles necessary for the absorption of the required quantity of papula; but also when that the spongioles are unable, from drought, or other causes, to absorb a sufficiency of nutrient matter, to sustain the rapidly developing and vigorous vegetation.

Plants propagated by cuttings cannot, of course, absorb the nutriment prepared and stored, during the last season, in the tubers of the mother root; and are forced to form spongioles and tubers for themselves. But the fecula contained in these latter is not, till towards the end of the year, sufficient in quantity, or sufficiently ripened by the deposition of carbon, to be in any way serviceable.

The potato might be propagated by cuttings of the young shoots, in the same way with the dahlia; but such plants would not, in the early stages of their growth, be nourished by the starch of the tubers; and, therefore, would neither be so strong and vigorous as plants raised in the usual method, nor would they yield a return equal in weight or quantity.

It is well known that tubers and bulbs, when placed in damp situations (the potato for instance in a damp cellar,) develop their leaf-buds; and that these continue to grow and elongate, without the assistance of rootlets or spongioles, so long as there is any fecula in the tuber or bulb; but that when this is exhausted the stem withers and dies. We hence perceive how important the nourishment derived from this substance is to the vigor of the plant, and why whole tubers of potatoes produce larger crops than are produced by cut sets. Hence, too, we may learn why perfectly ripe sets are so much more certain of success than unripe ones; the fecula in the former being so much the more abundant, and more perfectly elaborated. To the unripeness of the sets is attributable the failure of the potato-crops in some parts of Scotland, in the autumns of 1835 and 1836, and the consequent misery and starvation of the unfortunate peasantry.

I feel no doubt that much of the disappointment and dissatisfaction experienced by buyers of new varieties of the dahlia, arising from these so rarely answering the expectations formed of them, is the result of the system of propagating from cuttings. A good seedling is raised: the grower is naturally anxious to make the most he possibly can of it; he therefore plunges the root in heat, and strikes every cutting he can force it to throw out. The young plants are consequently weak and unhealthy, rarely throw out a good flower during the whole season, and are probably discarded, as undeserving of further notice. My first plant of Brewer's Rival King was a cutting from a root, which had been much worked, and consequently, did not show a good flower during the season. The next year, I grew it from tubers, and also from cuttings: the latter always produced imperfect flowers, but the former beautifully perfect ones. With many other varieties, I have found the same difference between plants raised from cuttings and those from tubers.

I would therefore recommend, in order to secure a good and satisfactory bloom, that the roots be laid, in March, in a damp warm place, such as a forcing-house, gentle hot-bed, or even a cellar; and that when the buds show themselves, each root be divided into as many pieces as may be required, retaining a bud to each piece; and that they be then planted separately in 48-sized pots. The after-treatment is the same as for plants raised from cuttings.

From the Horticultural Register.

FLOWERS, FRUITS, AND TREES.

By H. A. S. Dearborn.

Mr. Breck—The season having been unusually favorable for vegetation, and especially since the 15th of May, the consequent verdant and magnificent appearance of the country, with the blandness and congeniality of the weather, have induced vast numbers of persons to visit the many highly cultivated gardens in the environs of Boston, several of which have attracted universal attention, either from the great variety of ornamental plants they contain, or the beauty of some favorite kinds, that have been managed in the most skillful manner.

Mr. Walker's exhibition of tulips became the first chief point of attraction for nearly two weeks, and thousands were delighted, with the superb display, of that infinitely various and gorgeous family of flowers.

Other towns, it appears, have also enjoyed a like interesting spectacle; but a discrimination must be made between the merit due for quantity, and that resulting from the excellence of the varieties, and the perfection of their development. The enterprising gentlemen of Newburyport and Salem, are entitled to great credit, for the taste they have evinced, in the culture of elegant plants; but it is presumed they do not claim precedence, unless they had also as many kinds, which were as rare and perfect in florescence, as those which Mr. Walker presented; for the mere superiority in number, cannot be considered as giving preeminence, in any vegetable production, unless it is of some very peculiar or notoriously useful species.

To obtain bulbs of the best kinds of tulips from Holland, Belgium, France, and England, is very difficult and expensive, as every person has experienced, who has undertaken to introduce any particular plant from foreign countries. The bulbs, generally sent to this country for sale, are the rejected of the large nurseries, as all the most choice and valuable kinds are carefully reserved for the European markets, where the amateur purchasers are numerous, and willing and able to pay the highest price, for the remarkable varieties. Even in our day the extavagant passion for tulips has not entirely subsided, and from 500 to 1500 dollars have been given, within a few years, for a single bulb, while those disposed of, at our auction sales, do not average more than from five to fifteen cents, and often not so much. Some of Mr. Walker's cost in London fifty dollars each, and many of them from ten to twenty.

I have cultivated the tulip during a number of years, and had five thousand in bloom at one time, three thousand of which were in a bed, and the remainder scattered in the borders of the avenues and garden walks; but as a show of flowers, it was, in all respects, inferior to that of Mr. Walker's bed of only eight hundred, from the inferiority of the kinds, small number of distinguished varieties, negligent mode of cultivation, and imperfect florescence.

To give this superb flower an opportunity of displaying all its charming attributes, the soil must be deeply trenched, and enriched by a peculiar compost of thoroughly decomposed barn-yard manure, river sand, and decayed leaves or other vegetable matter, while a screen is indispensable to protect the plants, from the cold night air, the direct rays of the sun, and violent winds, when bursting into flower and during the period of their bloom. This Mr. Walker provided, at an expense of several hundred dollars, in a neat and complete manner, in the form of a beautiful pavilion, which was covered with stout white cotton cloth, so arranged, as to be easily rolled up, and let down, by means of pullies.

Tulips have been a favorite florist's flower for centuries, not only in Holland, but in England and other European nations; and as early as 1630, Parkinson, after enumerating one hundred and forty sorts, observes in his quaint manner, that "to tell of all the kinds which are the pride of delight, they are so many, as to pass my ability, and, as I believe, the skill of any other." He was a celebrated herbist and botanist, and acted in that capacity to James I, and Charles I. His book on gardening is the first which was published in Great Britain, worthy of consideration. It is entitled "Paradisi Insole Paradisus Terrestres; or a garden of all sorts of pleasant flowers, which our English ayre will admit to be nursed up; with a kitchen garden of all manner of herbes, roots and fruits for meate, and sause used with us; and an orchard of all sorts of fruit bearing trees and shrubbes, fit for our land, together with the right ordering, planting and preparing of them, and their use and virtues."

In Parkinson's time tulips were divided into *præcoces*, or early blowers, and *scrotinæ* or late blowers, with an intermediate class of *dubiæ mediæ*, doubtful or middle blowers, as they flowered between the two others. The early blowers, have short stems and the Duc Van Throll is almost the only variety in repute, among modern florists. The great number of distinguished and admired varieties are all produced from the late blowers, which, having tall stems and much finer colors, engross nearly the whole attention of the cultivators of tulips. The modern mode of classing the late blowers by the Dutch florists is as follows.

Prime Baguets, from the French word baguette, a rod, or wand; they are very tall, with handsome cups and white bottoms, well broken with fine brown, and all from the same breeder.

Rigaut's Baguets.—This variety is supposed to have received its distinctive appellation from some individual by the name of Rigaut, who was eminent in this branch of floriculture. They are not quite so tall as the former, but have strong stems, and very large well-formed cups, with white bottoms, handsomely broken with rich brown color, and all from the same breeder.

Incomparable Verports.—A particular kind of Bybloemens. Cups very perfect, cherry-red and rose-color and white bottoms, well broken with shining brown. Some of these are from ten to twenty-five dollars a root.

Bybloemens, or next flowers, called by the French *Flamands*. They have white ground, or nearly so, and are beautifully broken, with shades of purple and a variety of colors. They are from different breeders.

Bizarres, from the French odd, or irregular. Ground yellow, from different breeders, and broken with a variety of colors.

Paroquets, or Parrot Tulips.—The edges of the petals are fringed, colors brilliant crimson and yellow, with shades of bright green; but still they are held in no sort of esteem among florists.

Double.—These are of various, brilliant red, yellow and mixed colors; but, like many other double flowers, are deemed monsters, and not appreciated by flower fanciers, although they have an elegant appearance, from their upright, tall, and firm stems, and crowns of large pæony-shaped flowers, and when scattered, with the parrot, among the small shrubs and other plants in the borders of avenues and walks, or planted out in separate beds, they have a pleasing effect.

In the catalogue of Mosan for 1820, there are six sorts of early tulips, four of Paroquets, twenty-two double, and upward of six hundred late kinds.

Breeders are such as have been procured from the seed, and consist of one color, which is red, purple, violet, gray, brown, black, yellow, or some other individual color, without any sort of variation. These are cultivated in a rather poor and dry soil, and become broken, or variegated, in in from one to twenty years, and produce new varieties; but so uncertain is the prospect of a favorable result, that but few persons have been willing to make experiments, for after many years of patient and unremitted attention, there may not be one remarkable and choice variety, out of a thousand seedling bulbs. It is from this circumstance, that a new and superb tulip commands the high prices in Europe which have been named, and actually paid, within a few years.

When the tulip has broken, the colors are unchangeable, and are perpetuated by offsets from the parent bulb.

The tulips which are deemed worthy of special attention, by amateurs, belong chiefly to the classes of Bizarres and Bybloemens; and the properties of a fine variegated late variety, according to the best modern florists, are as follows:

Petals of a graceful form, the three exterior ones larger at the base than those of the interior; colors delicate, yet conspicuous, from the manner in which the tints are displayed, whether spotted, striped, feathered, blotched, splashed, pencilled, mottled, flaked, or as the French more significantly term the breakings of this flower *panaché*; edges entire and rounded, or but slightly crenated, at the summit, and so symmetrically arranged, as to form a perfect cup-shaped corolla, with a round bottom—except in some anomalous and remarkable kinds, like that called the mountain of snow, whose petals are slightly acuminated, recurved, a little undulate, and the flower leaning to one side. Stem strong, upright, and nearly thirty inches high; radical foliage, long, broad, undulating, and of deep rich green. The ground color of the bottoms of the cups should be clear, white, or yellow; the centre of each petal should contain one or more bold blotches or stripes, intermixed with small portions of the original color, abruptly broken into many irregular obtuse points. The colors which are generally held in the greatest estimation, in variegated striped sorts, are black, golden-yellow, purple, violet, rose, and vermilion, each of which being varied in different ways; but such as are striped with three different colors, in a distinct and unmixed manner, with strong regular streaks, and but little or no tinge of the breeder, are considered the most perfect.

An uncle of Mr. Walker, who resides near Windsor Castle, is celebrated for his tulips and ranunculuses, having produced several magnificent varieties of the former and many of the latter from the seed. His exhibitions of those universally admired flowers have been so superb, that his garden has been annually visited by the sovereigns, nobility, and that numerous portion of the population, of Great Britain who have a taste for ornamental plants. From him, the nephew has received many of his superior roots.

Besides the commendable exertions of Mr. Walker to present an interesting display of well cultivated and choice tulips, he has eminently succeeded in raising from imported plants and seed, numerous new varieties of the *viola grandiflora*—the most admirable of that large family of charming flowers. He has, in fact, made this large and brilliant pansy, known to New England, by the extensive seminaries, which he has established, and the multitude of plants which decorate his ground. He had seven hundred varieties in bloom at the time his tulips were in flower, and the corollas of some of them, were more than two inches in diameter. He also cultivates the ranunculus—one of the most delicate, beautiful, but difficult of all herbaceous perennial plants, to bring into a full and perfect florescence. He has two beds, this season, containing over two thousand tubers, and one hundred and thirty kinds, which, if the weather should not have been too hot, will present an exhibition of flowers as rare and interesting as that of his tulips.

To the above-named plants and the dahlia, Mr. Walker has devoted his sole attention, leaving to others the vast field of floriculture for the selection of their favorite flowers, and the distinction they have attained, or may acquire, from the intelligence, skill, and industry bestowed on their cultivation, and that complete success, which so amply rewards the ardent amateur.

The necessity of a division of attention to the several departments of ornamental and useful plants, is as obvious, as that of labor in the mechanical arts; and the advantages derived therefrom are as certain, as they are conspicuous and satisfactory.

Colonel Wilder is unrivalled, in this country, in the number, variety and successful cultivation of the camellia, the rhododendron, azalea, and rose, having over three hundred kinds of the first, and upwards of four hundred of the last named plants.

Mr. Manning, of Salem, has the largest variety of pears, he having made that delicious fruit his favorite object of culture, while the apple and plum have claimed his next regard. Mr. Wm. Kenrick is well known for his extensive and well-managed nursery of forest, fruit, and ornamental trees, shrubs, and herbaceous flowering plants; and for several years he has made most honorable efforts to introduce the morus multicaulis and other valuable species of the mulberry, for affording the best aliment to the silk worm. He has also the merit of establishing the first extensive nursery in New England, and has published a very interesting and useful work on fruit trees. He, with Mr. Manning, first succeeded in obtaining Mr. Van Mon's new kind of pears, and he has a collection of that kind of fruit trees, of great value, from the number of varieties.

Mr. Pond, of Cambridgeport, has become eminent for rearing large numbers of plum-trees of the most choice varieties, and also for his superior mode of raising asparagus.

The Messrs. Winship of Brighton, have a vast nursery, a large green-house and forcing-house, in which are collected a greater number and variety of useful and ornamental trees and plants, than are to be found in any other like establishment north of Long Island. Their importations of European forest-trees, and exotic shrubs, and herbaceous flowers, have been extensive, and contributed, in an eminent degree, to extend a taste for rural embellishment in the eastern section of of the union. Their collection of foreign new kinds of roses, rivals that of Col. Wilder, as they have some 500 varieties. Pæonies have also claimed their special attention, and they exhibit nearly 40 kinds.

Other highly commendable efforts have been made to multiply the fruits, culinary vegetables, and plants of all kinds, and especially by seeds. The establishments of Joseph Breck & Co., and of Hovey and Co., are well known, for they have so far kept pace with the rapidly increasing demand, and have so faithfully discharged their very responsible duties, in either raising or collecting the best varieties and of the most perfect quality, that they have merited and received the grateful acknowledgments of their numerous fellow citizens, who "drive their team a-field," or delight in the society, or the culture of the silent, yet eloquent, beautiful, useful, and ever interesting families of the vegetable realm.

As proprietors and editors of three of the most valuable agricultural and horticultural publications in this country, we are under the greatest obligations to them; and it is earnestly to be wished, that for all their diversified and indefatigable labors, they should receive that encouragement and reward, which will render their patriotic exertions annually more profitable to themselves, and useful to the public. In the diffusion of intelligence among the farmers and gardeners, and the extension of a taste for their honorable and important occupations, as well as for the improvement of the aspect of the country generally, by inducing a greater attention to all the branches of cultivation, those periodicals have already accomplished much, and if they receive that liberal patronage to which they are justly entitled, the beneficial results will be as universally conspicuous as they are desirable.

The new garden at Mount Washington, with its ranges of green and forcing houses, is becoming an object of great interest, and will soon rank among the first, which are now the most celebrated, as the intelligent and experienced Mr. McCollough has fully shown that he is well qualified for the station he has assumed.

The Charlestown vineyard, with its departments of other fruits, conservatories, graperies, and valuable, as well as ornamental plants, has given a well deserved reputation to the Messrs. Mason, from the successful manner in which the whole of their spacious establishment is managed.

The valuable, new, and excellent varieties of the strawberry, with which our market is enriched, have rendered Mr. William Mason of Charlestown, and Mr. J. L. L. F. Warren of Brighton, celebrated, for the zealous and successful exertions they have made to grow that delicious fruit. The Downton, Wilmot's, Keen's Seedling, Roseberry, Mulberry, Methven Castle, and other distinguished new kinds, are now abundant, and maintain the high character which they had acquired in England.

Mr. Town, of Snowhill street, in Boston, has a neat and well-conducted green-house, which may be truly called a floral gem.

There is an humble little cottage garden on the Dorchester road, near Grove Hall, which reflects great credit on the unassuming and respectable old man, who carefully tills it with his own hands; and many a passer-by has stopped to admire his beautiful collection of choice varieties of pinks. May he be made happy in his commendable efforts to contribute to the happiness of others, is a blessing which every visiter must spontaneously bestow on the venerable Meller, and at the same time, attempt to enable him to realize the benediction, in the purchase of a single root, or a bouquet of flowers. How interesting and imposing is it to behold the aged calmly and studiously engaged in the culture of a garden of flowers. They appear to be appropriately occupied in a kind of religious rite, and as if actuated by a presentiment that their end was near, devoting their last moments in the preparation of the materials of a garland for the decoration of their own grave, and thus seeming to ask the grateful tribute of approbation, from a life industriously and reputably passed, and now approaching its close, in the anticipation of that good name which all desire, and hope encourages us to believe may have been attained, and will be perpetuated when "we sleep in the narrow house of death."

There is very much wanted a large nursery of native forest-trees, where they shall be raised in such quantities, as to be afforded to purchasers at as cheap a rate as they can import them from England and Scotland. So great is the demand, that not only our nurserymen, but many individuals, have recently imported vast numbers. Two gentlemen, one residing in Watertown, and the other in Salem, have received ten thousand each, this season, which cost only a few cents a-piece. The quantities which might be sold, if furnished at even a liberal price, would be enormous; but the expense of obtaining trees from the forest, the mutilated manner in which they are taken up, and the consequent difficulty of making them flourish vigorously, deters those who would be glad to embellish their estates, or plant out wood-lots, or groves for timber, from making the experiment.

The rapidity of the growth of seedling trees, reared in nurseries, compared with such as are selected from the forest, is well known to those who have attempted the culture of both kinds.

A pleasing illustration may be seen on the magnificent ground of Col. Th. H. Perkins, who imported about thirteen years since, 15,000 plants which were not more than two feet high, and now they are large, healthy and beautiful trees.

Very respectfully,

Your ob't. servant,

H. A. S. Dearborn.

Hawthorn Cottage, Roxbury, June 20, 1838.

From the Mining Journal.

ANTI-DRY-ROT.

The following letter has been addressed to the the secretary of the Anti-Dry-Rot Company, by Mr. Samuel Beazley, the architect.

"Sir—At the commencement of the year 1836, I surveyed and accurately examined the posts and paling in the Regent's Park, for the purpose of ascertaining the comparative states of those timbers which had been prepared by Kyan's patent, and those which had not been submitted to the process of solution. In my report of that period, I stated that indications of decay were already perceptible in most of the unprepared timbers, both at the bottom of the posts, and in those arris edges and ends of paling which were placed, or had come, at all, in contact with the earth, while those timbers which were marked as having passed through the solution, were quite free from any such symptoms. I now beg leave to state, that I have this day, after a lapse of two years and a quarter from my previous survey, again accurately examined several of the same posts and paling, digging away the earth from the foundations for that purpose, and find that the symptoms of decay mentioned in my preceding report as having commenced in the unprepared timber, have so considerably increased, as to have rendered the bottoms of the posts completely rotten, to a depth of from one to two inches, and that, in several instances, fungi have been the consequences of the decay; while I find the prepared timbers which are in the earth sound and in the same state, with the exception of mere discoloration upon the surface, probably arising from the damp state of the earth at the time of its removal. As a farther proof of the difference existing between the unprepared and the prepared timber, we could cut with the greatest ease large pieces from the former with the spade, without using any force, while it required great exertion to chip off very small pieces from the latter."

From the Farmers' Magazine.

TEMPLEMOYLE AGRICULTURAL SCHOOL.

Any one who duly reflects upon the infinite importance of giving to the youth of our country an education wisely adapted to their prospects in life—to the peculiar character of an American citizen—to the nature of our institutions,—to our social polity and republican habits—must, we think, regret the failure of the bill so favorably introduced into the legislature, and so ably supported, of establishing a School of Arts under the supervisions and management of the Franklin Institute. It might be difficult to add much to the arguments so forcibly urged by the principal advocates of the bill; and we cannot but believe, that extended observation and maturity of reflection will eventually satisfy every parent and guardian that he could make no better provision for the prosperity of a son or a ward, destined to fill an active and productive sphere of life, than to place him in a school where, in addition to the requisite amount of literary instruction, he may acquire a knowledge of those practical sciences, to which his time and energies must necessarily be devoted. Such a school as that whose outlines and objects were presented to the legislature, would furnish incalculable advantages to those who have in prospect an engagement in any of the arts, trades and manufactories which are becoming so immensely important to the wealth of our country. To those whose views are more exclusively agricultural, such establishments as the one described in the subjoined article would be worthy of all imitation.

G.

To the Editors of the Irish Farmer's and Gardener's Magazine.

Gentlemen—You will render a service to Ireland, and advance the interests of that branch of her industry (agricultural) whence she derives her principal resources, by giving a place in your widely circulated pages to the following account of an establishment now in operation for ten years, the extension of which, and the formation of similar schools elsewhere, are the sole rewards aimed at by the noblemen and gentlemen who were the founders of it, of whom many are still zealous, as the committee of management, in promoting its success.

I have the honour to remain, gentlemen, your ob't. humble serv't.

One of the Committee.

The Agricultural Seminary of Templemoyle originated at a very numerous meeting of the North-west of Ireland Farming Society at Londonderry, and it was at first intended that it should consist of two establishments, taking Mons. Fellenberg's Institution at Hoffwyll in Switzerland in some degree as the model: the first to be a school affording instruction in every science and accomplishment aimed at by the children of the higher orders; the second for the education of the sons of respectable farmers and tradesmen, in the hope of disseminating the advantages of an improved system of farming with greater certainty by combining the practice and theory of it in the instruction of those who were afterwards to make agriculture their pursuit, it was hoped, that the extended scale of the institution would have allowed of a greater variety of masters and lecturers, and that the profit derived from the superior school would have contributed towards the maintenance of the secondary one; but a short experience convinced the subscribers that such a scheme was impracticable without much larger and more certain funds than they could rely on; they then gave their undivided attention to the agricultural seminary, which through their increasing exertion has attained such eminence as may justly entitle them to look forward with confidence to its increasing usefulness, and to its becoming a model for establishments of a similar nature in other parts of Ireland.

The school and farm of Templemoyle are situated about six miles from Londonderry; about a mile distant from the mail-coach road leading from Londonderry to Newtowlimavady. The house, placed on an eminence, commands an extensive and beautiful view over a rich and highly cultivated country, terminated by Lough Foyle. The base of the hill is occupied by a kitchen and ornamented garden, cultivated by the youths of the establishment, under an experienced gardener. The ground between the garden and house is laid out in beds in which all the different grasses, clovers, &c., are cultivated with the greatest care. The house is in the form of an ||=||, with ranges of farming offices behind, containing spacious, lofty, and well ventilated school-rooms; refectory, dormitories, apartments for the masters, matrons, servants, &c.

Each pupil occupies a separate bed; the house can accommodate seventy-six, and the number of pupils amounts to sixty. They receive an excellent education in reading, writing, and arithmetic; book-keeping, mathematics, land-surveying, and geography. This department is managed by an excellent head master and assistant master, both resident in the house. The pupils are so classed that one-half are receiving their education in the house, while the remainder are engaged in the cultivation of a farm of 130 Cunningham or 165 statute acres, in the management of which they are directed by the head farmer, an experienced and clever man, a native of Scotland, who has a skilful ploughman under him. The pupils who are employed one part of the day on the farm, are replaced by those in the school, so that the education always advances in and out of doors *pari passu*.

The pupils are thus instructed in all the practical parts of farming, and are also lectured several times a week on the theory of agriculture. They are made acquainted with all the properties of different soils, the manures most applicable, and the crops best adapted to each; points in which most of our practical farmers display great ignorance. They are also made acquainted with all the numerous varieties of cattle, and their qualities, such as early maturity in some breeds, hardihood in others; and have strongly impressed on them that one of the most essential points in farming, is to select the cattle and the crops best adapted to the situation, soil, &c.

The stables, harness-rooms, cow-houses, winter-feeding houses, piggeries, barn, tool-houses, are arranged in the best manner, and the pupils are required to keep them and their contents in the highest order. A respectable and intelligent matron has the superintendence of the dairy, cooking, and cleaning the house, and the charge of the domestic servants.

The formation of this establishment has caused its founders an expenditure of above four thousand pounds; of which about three thousand were raised at its commencement by shares of £25 each, by the noblemen, gentlemen, and members of the North-west Society. The Grocers' Company, on whose estate it is situated, have been most liberal in their assistance, and have earned a just reward in the improvement of their property, by the valuable example the farm of Templemoyle presents to their tenantry; and it is gratifying to state, that the example is not confined to so limited a circle, but is followed, to a very great extent, by the farmers to a considerable distance.

In sending a pupil to Templemoyle it is necessary to have a nomination from one of the shareholders, or from a subscriber of £2 annually. The annual payment for pupils is £10 a year; and for this trfling sum they are found in board, lodging, and washing, and are educated so as to fit them for land-stewards, directing agents, practical farmers, or surveyors, schoolmasters, or clerks.

From fifteen to seventeen is the age best suited for entrance at Templemoyle, as three years are quite sufficient to qualify a student possessed of ordinary talents and a knowledge of the rudiments of reading and writing, to occupy any of the above situations. If this very short and imperfect sketch of what must and will become a more generally useful institution, as it is more known and appreciated, should lead the reader to wish any fuller information, he may easily be gratified by visiting the agricultural seminary, or by applying to the zealous secretary to the committee, Pitt Shipton, esq., Londonderry, under cover to Sir R. A. Ferguson, Bart, M. P., who will furnish printed reports containing the history of the rise and progress, the names of the shareholders, the rules and regulations of the society, hours of school and labor, dietary, and a variety of minutiæ, which, though extremely valuable and necessary to be known, yet from their length might prevent the insertion of this outline of the Templemoyle Seminary in those works which, from their circulation, may both increase the utility of the publication, and the knowledge of an institution of which the advantages have been felt and appreciated in the north of Ireland.

N. B.—Upwards of two hundred young men, natives of sixteen different counties in Ireland have passed through, or remain in the school. Of these between forty and fifty have been placed in different situations, such as land-stewards, agents, schoolmasters, and clerks, or employed on the ordnance survey. Nearly one hundred are now conducting their own or their fathers' farms in a manner very superior to that of olden time; and the accounts of those who have been placed from the seminary are such as to gratify the gentlemen who have its interest at heart, and to convince them that the good seed sown is producing an ample and valuable harvest.

Templemoyle, Oct. 14, 1837.

[It gives us unqualified pleasure to lay before our readers the above gratifying account of an institution so eminently calculated to confer lasting benefits upon the country. We have been long strenuous advocates for the establishment of agricultural schools in all parts of Ireland, feeling assured that they would ultimately be the means of breaking down those absurd prejudices which have been hitherto the most insurmountable obstacles with which agricultural improvement had to contend.—*Editors.*]

NEW PLAN PROPOSED FOR DUNNING DELINQUENT SUBSCRIBERS. MARYLAND TWIN-CORN.

To the Editor of the Farmers' Register.

Chillow, April 20th, 1838.

Dear Sir—Enclosed I send you ten dollars; whether more or less than the amount due you, I can't say; if less, please advise me by an account upon your next number.

You publish in every number the names of those who make payments; why not publish on another leaf the names of delinquents and the amount due by each? I think it would be an excellent regulation. It would have very much the effect of mounting a truant school-boy upon a "dunce-block"—none ever desire to attain that honorable destinction a second time, nor would your subscribers ever desire to appear twice upon the delinquent list. In ninety-nine cases of a hundred it is procrastination, and not inability to pay, that keeps us delinquents from forwarding our subscriptions. It would be a cheap and sure substitute for the impertinent little gentlemen who so uncivilly remind one "that they will be glad to get your subscription for the Farmers' Register, Whig, Enquirer," &c.

In your article upon "Hobbies and Humbugs" you quote from Mr. Carmichael the following, viz: "My experience (speaking of the Maryland twin-corn,) induces me to think that no great advantage is derived, if this corn is planted on lands naturally poor, or exhausted by cultivation; but when in a state of fertility, either naturally, or by improvements. I think the [increase of] product from this kind of corn will be more than fifteen per cent. My whole crop the last year was Maryland twin-corn, and I thought I observed a manifest advantage from its cultivation upon bottom land and good up-land. I am not prepared to say what per cent. it yielded above the average crops of common corn heretofore made upon the same land; but it was, I am perfectly sure, much the heaviest crop I ever saw upon the bottom and good up-land. I should *guess* at least by one-fourth. The case, however, was very different upon the exhausted parts of the field—for there, the corn over-shot, and produced very little more than stalk and fodder. It will not do, so far as my limited observation extends, upon any other than land that is (in common parlance) in "good heart," so well as our old corn, viz: gourd-seed and Dearing corn.

This, however, I do not consider any objection, for no man ought to put exhausted land in any crop for profit; for, if he does, he will verify the vulgar maxim of "working for nothing and finding himself"—this I have learned by sad experience. I have tried it ten years, and have always found my profits on the wrong side of the leger—and of a man who would have the nerve to push such an experiment farther, it might be truly said, that "there is more hope of a fool than of such a man." Can you not coax some good man of meadows to give us more light upon the art of grass culture? For one, I should be very thankful if you would convert a part of your domain, (the Farmers' Register,) into meadows of a standing pasture, where we corn-fed nags might luxuriate in fine grass; and mix hay with our grain—*Verbum sat.* With hearty good wishes for the success of your efforts, I am, dear sir, your obedient servant,

P. A. Bolling.

REMARKS SUGGESTED BY THE PLAN ABOVE PROPOSED.

If all subscribers were as well disposed as our correspondent, to be reminded of, and to correct, their errors of omission or procrastination, then the very simple and cheap plan of notification which he proposes, would save a great deal of trouble and of expense, of vexation and sore feeling, both to the publisher and to delinquent subscribers, which is now necessarily incurred, in the sending bills separately (and often repeatedly) by mail, and the maintaining the usual system of collecting debts through travelling agents. And though (for reasons stated at large in a former number) the use of collecting agents, in Virginia, has been entirely abandoned for this publication, the discontinuance of that mode of personal application makes written applications the more necessary, and leaves in action abundant sources of discontent and displeasure to persons so notified, and of vexation, and wounded feelings, besides "patronage" forfeited, and pecuniary loss incurred, by the publisher. This is, by far, the most disagreeable and galling of all the burdens which the publisher of a periodical work has to bear. It is not so much the enormous per centage of loss, upon the whole amount of debts due, that is and must be sustained, as the numerous cases of offence, unintentionally given, and not unfrequently of greater offence, intentionally returned, in consequence of the mere notification to delinquent subscribers of their dues, in such general form, of circular letters or otherwise, as the cases in general require. No man, who has the sensibility of feeling, and delicate sense of honor, that a gentleman should have, would undertake the endurance of this odious duty and burden, if he knew its magnitude before he commenced the labors of editor and publisher. For our own part, we thought that the plan of printed receipts for monthly payments, which was adopted from the beginning of this work, would prevent any continued ground of mistake or misapprehension of subscribers, or of just complaint on that head; and leave us no ground for the "wear and tear" of feeling, and of temper, in contemptible and irritating contests about five-dollar debts. In these printed lists, (unless omitted by mistake,) the payment of every subscriber appears in the month in which it is received; and the preservation of that cover, or a mere reference to it, is the most convenient and best of vouchers, inasmuch, as so many hundreds are printed, that it is scarcely possible that every copy of the receipt can be lost. Moreover, the notification of any omission or mistake in these receipts is requested in every list, and immediate correction of all such promised; and in every case of information of error, whether given early or late, (and no matter how defective the proof,) the correction has been promptly granted. With such ample means afforded by our regular usages, it is manifest, that if any subscriber is overcharged, (by omitting his proper credit of payment,) and remains so, it is his own fault, in not furnishing the means of correction. With all the care that can be used, some mistakes, and consequent overcharges, cannot be avoided; but no such overcharge can remain two months on our accounts, if subscribers will merely look for their names in the lists, preserve the copy, or a reference to it, and give notice of errors discovered. With such a system, the publisher may *lose* in many cases by mistakes made in entries, but cannot possibly *gain* by one. And it is as foolish and unreasonable as it is unjust, for any overcharge to be imputed to design, which would be an act of dishonesty as contemptible in its object, as for its motive. We have committed very few mistakes of this kind, compared to the number made by our subscribers—and much fewer than their mistakes of the opposite kind, where they have paid more than they owed, and consequently were credited for a year more than they expected. It never entered our mind to suspect that any subscriber meant to defraud, by his statement of his dues and payments falling short of the true amount; and when the publisher has every thing to lose, and nothing to gain, by similar mistakes and misstatements of account, surely he is entitled to at least as much indulgence and respect.

But the mere possibility of any such overcharge existing, would be a sufficient objection to the plan proposed, of printing the list of names of all supposed indebted subscribers; and, besides, we should be very unwilling to take that mode of reminding debtors, who had not been *very* forgetful of, and remiss in, performing their obligations. But neither objection applies to cases of long-continued neglect and denial of payment, even after a year or more has elapsed after the names have been erased from the subscription list, for non-payment of still older arrears. Such a list as this, may be published before another volume of the Farmers' Register is commenced; and we fear (from present appearances) that it will be a long one.

From the American Journal of Science and Arts.

HYDROGEN GAS IN A LEAD PIPE, USED AS AN AQUEDUCT.

In a letter to the Editor from Nelson Walkly.

I was at the house of a friend during the last summer, and while there, he was engaged in laying lead pipe, from a spring to his house, for conducting the water, a distance of three-quarters of a mile.

Between the spring and his house was a hill several feet higher than the spring, and several whose summits were not as high. His house was fifteen feet lower than the spring. He informed me that he had laid down his pipe several times and set the water running, but it never had continued to run over ten days at a time. He had repeatedly taken it up and tried it, supposing it contained a leak. He called on the man whom he had originally employed to lay his pipe, for a cause, and found that he knew nothing, except that the stoppage was occasioned by air, and that air could not get in, unless there was a leak in the pipe. My friend, when I arrived, was taking up his pipe for the last time, to try whether there was a leak. After trying it with a pressure of 50 lbs. to the inch, he found no leak and laid down his pipe, and by means of a forcing pump set the water running again. As formerly, after running less and less for about ten days, it entirely ceased. I then took it in hand, determined to find out, if possible, the cause of the obstruction. I made a puncture in the pipe at one of the high places lower than the spring, and found that the pipe contained not air, but hydrogen gas. I was now more embarrassed than before, as I could not imagine what was the source of the hydrogen. I happened about that time to take a tin cup of water, and noticed a row of minute bubbles along the seam; the thought struck me, that it was the combination of metals in the pipe that occasioned galvanic action sufficiently powerful gradually to decompose the water.

To try it, I put a small piece of the same pipe into a tumbler of water, and after standing two days, I found the pipe covered with a coat of white oxide, with the exception of the seam where it was soldered together, and there the tin which composed the solder was perfectly bright. From this I inferred, that the galvanic action of the pipe on the water produced decomposition, the oxygen combining with the lead, and the hydrogen carried along by the water until it came to the high places in the pipe, and there accumulated until it filled the pipe and entirely obstructed the water.

To remedy this difficulty, I made holes into the pipe at every high place, and soldered over them a vertical tube, open at the top, excepting the hill that was higher than the spring, and to that part of the pipe I soldered a tube similar to the others, with this exception, that I soldered it up at the top. The first mentioned tubes let the gas escape as it came along, and the one on the highest elevation suffered the gas to accumulate in it until a small bubble protruded below the end of the vertical tube, and was detached from the body of the gas in the tube and carried on by the water. After the above arrangement was effected, the water was set running, and has continued to run without any sensible diminution ever since, upwards of eight months. Query, Is not the action of water upon lead, mentioned in vol. xxxiv. p. 25, of this journal, occasioned by a combination of some other metal with the lead?

Tuscaloosa, Ala. May 25th, 1838.

From the Genesee Farmer.

WHITE-WASHING TREES.

The practice of white-washing trees, particularly fruit trees, which at one time prevailed extensively, seems to have been mostly discontinued, but for what reason, is not, we apprehend, generally understood. Washing trees with lime was adopted for the purpose of removing mosses, cleaning the bark, destroying insects, particularly the aphis, and that it was efficient for these purposes, few who have tried it will deny. The objections made against the practice were that the coating of white-wash excluded from the bark the action of air and moisture, and that by causing the rough bark to scale off, the tree was deprived of a covering which might be beneficial in protecting it from frosts in our severe winters. These objections we are inclined, from our own experience and observation, to consider of little weight when compared with the positive advantages of the application. We have never known a tree injured from the white-washing process; on the contrary, we have seen trees covered with the aphis, or with dead rough bark, effectually cleaned, and rendered vigorous and healthy, the bark looking green and the foliage vigorous. To produce the beneficial effects, it is not necessary to have the white-wash laid on of the consistence and thickness of a coat of mortar; but thin and even with a common brush. If the tree is very mossy, or has much dead bark, rubbing it with a stiff broom, or otherwise cleaning the trunk, should precede the application of the white-wash. Experiments have shown, that in nurseries of trees, those that have been washed either with lye or lime, grew much more rapidly than those not subjected to the process. We should be pleased to have the opinions of our farming friends, on this subject.

From the Genesee Farmer.

OIL-CAKE AND BONES EXPORTED FROM AMERICA TO EUROPE.

A vessel lately sailed from New York for England, carrying out more than one hundred tons of oil-cake, for stall-feeding cattle. This shows that the English farmers understand the nature and value of that material better than we do, or instead of sending it abroad, we should use it in fattening beef at home. The exportation of oil cake we do not, however, consider so suicidal to the interest of the farmers as that of bones; of which, within a few years past, very large quantities have been collected in the vicinity of the principal cities and sent abroad. This is directly robbing ourselves, by depriving us of the means of communicating and perpetuating fertility to the soil. The beef made by the oil cake will not, it is probable, be sent to this country for sale, but from the example of the past, it is very possible that the grain produced by the application of this bone dust may be returned to our shores, when by its use here, the same wheat would have been raised, and the land at the same time permanently benefited. Our farmers will do well to think of these things.

From the Quarterly Journal of Agriculture.

ABUSES OF BONE-MANURE.

The character of bone-dust as a trusty manure for turnips, runs the risk of being depreciated by the injudicious manner in which that manure is sometimes applied to the soil. It is found, in singling the turnip crop, that the bone-dust is liable to be brought up to the surface of the ground by the root-fibres of the ejected plants. From this circumstance, it is conceived, that a stratum of earth betwixt the bone-dust and the turnip seed would prevent the recurrence of the evil; and accordingly, to effect this purpose, the bone-dust, in some instances, is either dropped into the drill by the hand, covered up by the plough, and the turnip-seed sown in the drill by the common turnip sowing-machine, as in the case of farm-yard manure; or the bone-dust is first sown by one machine, and then the turnip-seed by another, immediately or shortly afterwards. These plans are practised in the borders of England, and Scotland, a part of the country which is occupied by farmers, whose common sense, independently of their agricultural skill, might have warned them against their dangerous consequences. Such a practice could only have originated from giving no heed to the nature of bone-dust, and the growth of the turnip plants towards maturity.

It is clear, that if a stratum of earth intervenes betwixt the manure and the turnip-seed, a *quick* braird of the turnip plant cannot be insured. It was the slow brairding of that plant which formed the ground-work of the universal complaint against farm-yard manure, however well prepared, for raising turnips, on dry soil in a dry season, and especially on strong land in a dry season; and the great recommendation given with bone-dust, was that of its *insuring* the early braird of the turnip-plant in all seasons. The complaint now, under the practice above described and condemned, is, that bone-dust does not insure an early braird of turnip in strong land; but, so long as the practice of placing earth betwixt the manure and the seed is followed, a quick braird ought not to be expected. Contact with manure will cause turnip-seed to vegetate in a short time. Could the seed have been placed in contact with farm-yard manure as easily as with bone-dust, the latter would never have acquired the fame it has as a turnip manure. The firmness with which the roots of the turnip grasp the manure, shows the great capacity for manure which they possess in the early stage of their growth. It is this tenacity for manure of the root-fibres which raises so much of the bone-dust to the surface of the ground, by adhering to the roots of the ejected plants; and whenever turnip seed vegetates in contact with farm-yard manure, the same inconvenience results. In the case of dung being brought to the surface, it there becomes wasted, but in the case of bone-dust, the resurrection of the bones not in contact with the growing plants, is of no consequence, because, while exposed to the air, the bones lose none of their fertilizing properties; and none of them which are brought up escape being again covered by the subsequent operations of hoeing, scuffling, and earthing-up. Although the bone-dust should be scattered between the drills, if it is at all under the surface of the ground, the long and tender fibres from the turnip-plant, which extend a considerable distance around every plant, will eventually derive benefit from it. But even should any of the bone-dust be left exposed to the air, on the surface of the ground, after all the operations are completed, it is much better to suffer that loss, than run the risk of losing the whole crop by improperly checking the braird. Eventually the bone-dust cannot be lost, for whenever, by any means, by ploughing, by tramping of sheep, it is pushed into the soil, it immediately imparts its properties to the soil. The increasing scarcity of bones, and the consequent advance in price of bone-dust, from 2s. 6d. to at least 3s. if not 3s. 6d. per bushel, and which difference of price, small as it may appear, constitutes a considerable additional expense in the turnip-crop on a large farm, has no doubt suggested the adoption of this pernicious practice; but although economy in the use of bone-dust is a laudable endeavour, it should never be attempted at the risk of the well-being of the crop. Bone-dust may be economically used by mixing it with ashes, whether derived from the combustion of coals or peat; or where farm-yard manure is abundant on any farm, let some of it be spread in the drills in the usual form, and the seed afterwards sown along with bone-dust on the tops of the drills. In this case, the manure need not be much prepared, as it will have time to ferment in the ground before becoming useful to the turnip-crop, while one-half of the usual quantity of the bone-dust, namely, one-quarter per imperial acre will suffice for the brairding of the plant and its nurture, until it finally depends for support upon the manure.

On considering the effects of bone-dust on land, it is not improbable that the experience of years may prove the abatement of its efficacy as a manure, after repetition of its application on the same ground. This appears to be the opinion of the Duke of Portland, as expressed in a communication by the duke himself, in Bell's Weekly Messenger of 23d April, 1838. As we know that his grace is an accurate observer of the operations of the field, his statement is worthy of an attentive perusal.

"In 1834, two fields of sand-land adjacent to Clumber Park," says his grace, "the one at right angles to the other, each containing about twenty acres, were sown with seeds among barley. Whenever these fields had been sown with turnips for twenty years before 1825, they had always been manured with bones. In that year they were largely so manured. The seeds sown with barley in 1826 having been burnt up in that dry summer, in 1828 the land in both these fields was again broken up. In 1829 it was again fallowed with turnips and manured with bones. In 1833, both these fields were again sown with turnips, parts of each of which were manured with bones, and the remainder with farm-yard dung.

"In 1834, when the corn was out, it was found that the seeds had failed in each of these fields where the bones had been applied; and that they were very good where they had been manured with dung. In one of these fields the failure exactly followed the line of the difference of the manures, with two exceptions, that the seeds did not quite fail in two spots where formerly there had been dung heaps. In the other field the failure did not so exactly follow the line of demarcation, but the exceptions were very few. Generally speaking, the manured land is better than the boned land, but the difference of quality is not great, the crop of barley on the manured land had been at the rate of five quarters per acre, on the other four.

"Immediately after harvest, fresh seeds were sown on the boned land. They came up very thick, but in six weeks died and disappeared. During the winter the land was again fallowed, and fresh seeds were again sown in the spring of 1835. They cannot be said to have failed, but they were a very inferior crop; and, notwithstanding a manuring of farm-yard dung applied as a top-dressing the following spring, they have not yet recovered a parity with the rest of the fields. In this case it seems impossible to attribute the failure of these seeds, where they have failed, to any other cause than the bones, which had certainly been applied with unusual abundance; and it is the more surprising that such a cause should have produced such an effect, because, in the early periods of the use of that manure, it appeared to be in no respects more advantageous than in its tendency to encourage the growth of the clovers. Of this tendency, the most remarkable instances have been repeatedly seen on very poor land, and none more so than one which occurred on a very poor piece of land prepared for a plantation by a crop of turnips, manured with forty bushels per acre, on which, between the trees, a great deal of clover has spontaneously sprung up. Previously to this land having been broke up for turnips, scarcely a plant of clover was to be seen. Now the fields on which the seeds have failed had (as above stated) received, much more frequently than usual, complete dressings of bones.

"Combining the great advantages of bones on the first application of them with this failure, it seems difficult to avoid the conclusion, that as the bones, while they are new to the land, have produced the most beneficial effects, and as this failure has taken place where their application has been most frequently repeated, the success is in a great measure owing to the novelty, and the failure to the repetition of their application.

"If the preceding statement required any confirmation, it has received it in 1837. In this year, a field which had been turnips in 1836, had been laid down to grass. The north side of this field is very inferior sand-land; and as, till lately, it was supposed that such land would not pay for the expense of bones, they had never been applied to it. For the first time in 1836, bones were used for the turnip fallow. The south side of this field, which for many years has always been manured with bones when in fallow for turnips, was divided into four divisions; the western side was manured with farm-yard dung; that next to it with bones; the two eastern divisions were manured, the one with rape-dust, and the other with malt-culms. After harvest, the seeds on the north side appeared to be best; then those on the western side of the field; then those on the two eastern divisions, which were rather inferior; and those on that where the bones had been applied were visibly the worst. The frost has been so injurious to the seeds, that this difference between the three eastern divisions is not now so marked as it was before the frost; but the superiority of the northern side and the western division is very apparent.

"This field lies nearly opposite to Scotland Farm, on the other side of the road leading from Ollerton to Worksop, and three miles from the latter."

In this statement the soil is described as "*sand-land*:" the rotation followed on it a four-shift, viz. turnip-fallow, barley, grass, and a white crop; and the quantity of bone-dust applied forty bushels per acre. The remarks we would venture to make on this statement are, that a rotation of four is not adapted to any "sand-land" with even an unlimited command of manure; for that course keeps light land too much under the plough, makes it too pulverulent, and thereby endangers its texture with deafness. Such land should always be *pastured* at least two years, and better still for three, in order that it may be consolidated into a firm condition by time and rain, and the tread of animals. It is not stated whether the turnips were wholly carried off the ground, or partly eaten on the ground by sheep. We have, universally in Scotland, a notion that the half, at least, of the turnips raised by means of bone-dust ought to be eaten off by sheep; for, without such assistance from other manure, we conceive the bone-dust would have too much to do of itself in supporting all the crops during the rotation. This being the notion in Scotland, the practice originating from it is, that never more than sixteen bushels generally, though some farmers apply 20 bushels, is applied to the imperial acre. We have also a notion in Scotland that bone-dust has a caustic quality, and that considerably more than sixteen bushels to the acre on light soils, would do more harm than good. We have ourselves experimentally tried the effects of different quantities of bone-dust in raising turnips on light gravelly soil from twelve to twenty-five bushels per imperial acre, and found the crop improved decidedly to sixteen bushels, but not in the least beyond that quantity. So far, therefore, as the turnip crop was concerned, any quantity above the sixteen bushels was thrown away. The circumstance, as expressed in the statement, that farm-yard manure yielded more barley on the "sand-land" than bone-manure, after the land had been previously boned, shows analogically the fertilizing effects of feeding sheep at turnips on land that had been manured with bones. Until, therefore, we learn that turnips had been raised on the "sand-land" with only sixteen bushels per acre; that at least, the half of them had been eaten off the ground by sheep; and that the grass after the barley had been pastured at least two years, we are more disposed to ascribe the failure of the grasses to the system of farming described by the duke, as being quite inapplicable to such soil, than to injurious effects from the bone-dust.

From the Franklin Farmer.

HARVESTING OF CORN.

To the Editor—As the season is approaching in which the farmers will commence the securing the abundant crop of corn with which a bountiful Providence has blessed our country, it may be pertinent to the occasion to offer a few remarks upon the best mode of harvesting the crop.

Our Virginia ancestors and those who think it wise to plant and cultivate and gather as our fathers have done, pursue the old method; about this time they gather the blades below the ears of corn—after they consider the corn to be ripe, they top the stalks and secure all of the fodder in stacks for winter use. In November they pull the corn and remove it to cribs, where it is husked out at leisure. This mode is rapidly yielding in the stock districts to that first introduced among the graziers on the south branch of the Potomac. The farmers in the northern and middle districts of Kentucky, and in the Scioto valley of Ohio, have generally adopted this latter mode; which is to cut the stalks, corn, fodder and all, and place them in shocks commonly embracing sixteen hills square.

I have seen the richest crops of many climates gathered, and there is no operation in husbandry so animating as that of cutting corn in the mode just mentioned. It is a most cheering prospect to see twenty acres of corn pass in one or two days to a condition in which it is prepared to keep in the field throughout the winter. This remark is predicated particularly upon the plan of riddling the squares, instead of cutting the whole square at once. It will readily occur to any observing mind, that as corn does not ripen with precise regularity, if the entire square is cut out at once, some of the corn will mould and sometimes even the fodder will be affected, if the cutting shall be followed by warm or wet weather. To avoid this contingency, some graziers commence with the process of riddling, that is, they select only such part of the sixteen hills square as may be ripe —go through the field in this way, and in ten days complete the cutting of the square. By this process several important advantages are obtained— the greatest amount of fodder is secured, consistently with the paramount object of saving the corn, and a nucleus for the shock being formed by the first cutting in the square, the shock becomes settled and stands better during the winter. In the rich counties of Clark and Bourbon, they sometimes cut half of the square on one side and then in ten days finish it. Whilst many graziers in Fayette, Lincoln and Shelby, prefer the process of riddling.

In the course of October and November, these shocks are shucked out, the corn placed in cribs and two of the shocks placed together, or one placed upon the ground and two others put around it.

It is the opinion of practical farmers, that the practice of cutting corn in this mode secures the greatest amount of corn and fodder with the least expense, and is decidedly an improvement on the old Virginia plan, more especially when applied to the feeding of cattle or mules.

THE ADVANTAGE OF "SWATHING" WHEAT, IN REAPING, INSTEAD OF "HANDING."

To the Editor of the Farmers' Register.

This year the luxuriant growth of my wheat induced me to think that it could not be saved by the long scythe and cradle, and handled by the binders, in the usual way, to advantage. I reduced my scythes and cradles to forty-eight inches, and swathed my wheat. Being satisfied, from observation, that this method of saving my wheat is greatly to be preferred to the one I formerly pursued, I will state the manner in which the work was done; and if you or your readers should esteem this hobby-riding, I am quite willing you should indulge the laugh. I do not think, according to your definition, you can bring it within the class of humbugs. As I understand you, hobbies generally bring loss to the owners; humbugs are started by the jockeys for profit.

The stroke of the cradler brings him half round on the land, and, by raising the heel of the cradle, he lays the wheat across it; his hands both remain firm on the sneed, the weight of the wheat rests upon him, but for a moment. The motions being freer than when he gathers by the hand, he cuts faster, and with more ease to himself. My people disliked the change at first, but soon became accustomed to it. I had two or three lands cut before the rakers and binders started. Four rakers (the rakers collecting two lands) and seven binders kept without difficulty the distance at which they started, and would have overtaken the cradlers, if I had permitted, and sometimes, in my absence, did so. The task of rakers is easy; by a little care they collect all the wheat which is cut off, and by gathering it in bunches of a proper size, the binder has to make but one stoop for a sheaf, and there are no scattered heads to be collected by hand, which greatly lessens and lightens his labor. My crop was unusually heavy; but I never gathered wheat at so little loss. My usual practice has been to run a horse-rake after the binders: but so little was left this time, that I deemed it not worth the cost. The experience of the harvest has convinced me, that by this method, unless the wheat is much down, it can be better saved than by the sickle.

In New York and Pennsylvania, swathing is the usual method of gathering wheat; but I never before saw it in Maryland. If it be the common practice in Virginia, it would be useless to give this a place in the Register. To communicate to farmers what they know, is in as bad taste, as to tell to a company a good story which they had heard before. Among the complaints made by Sir John Falstaff against Justice Shallow, one was, that he was ever on the rearward of the fashion, and sung old tunes which carmen whistled. I have no inclination to be numbered in the family of the Shallows, though the connexion is pretty numerous, and some of them wear fine linen, and sit in high places.

Mr. Hussey, the patentee, had his wheat-cutter in this neighborhood during the harvest, which did its work perfectly. I saw the performance, and do not think it left one head in a thousand. The only objection (which is a serious one) is, that it does not do enough. I understand that from fifteen to eighteen acres is as much as it can cut in a day; and you well know that a protracted harvest is often attended with serious loss.

RUSTICUS.

Eastern Shore, Md. July 28, 1838.

[The general practice in lower Virginia, is to catch the reaped wheat from the cradle in the left hand, and then to throw it, (two or more such handfuls together,) to be picked up by the binders. This usage could not have been commenced, except where the growth was light and thin; and nothing but the difficulty of changing the old practices of laborers, has prevented this mode being abandoned, on good lands, for that recommended by our correspondent.—ED. FAR. REG.]

From the Cultivator.

AGRICULTURE IN FRANCE.

There are at present in France 123 agricultural societies, and 303 agricultural committees, where, before 1803, there were scarcely ten, and they are constantly increasing. Every thing has been done by the present government to encourage agriculture in a pecuniary way, as well as by the different societies. The sum of 500,000 francs—nearly 100,000 dollars—has been placed at the disposal of the French minister of public works, for the encouragement of agriculture during the year 1838. There have been also several gentlemen travelling in Scotland, at the expense of the French Society of Agriculture, in order to examine the system of farming in that country.

From the Cultivator.

A HINT TO CATTLE BREEDERS.

T. A. Knight, the very distinguished horticulturist, publishes in the Farmers' Magazine, a communication on the ill effects of overfeeding young stock. Young cattle thus brought up, when taken into other districts, have been found, with their offspring, incapable of thriving upon common pastures. Animals, he thinks, which have been overfed from their birth, and whose ancestry have been subjected to the same treatment, acquire a power of eating and digesting a much larger portion of food than others. He admits that the improved Durhams are brought to market at a very early age, oxen of very great weight and excellence; yet he says it is well known that all those young animals come to market deeply insolvent, the sums for which they are sold being greatly less than those expended in feeding them. In illustration of their expensive keep, he cites the following facts:

"Three Herefords and three Durhams," says he, "were put into stalls, to be fatted on the third of November. The weight of the Herefords was then 33 cwt. and that of the Durhams 38 cwt. and 14 lbs. Between that period and the 30th March, when all were sold in Smithfield, the Durhams consumed 12,755 lbs. weight more of turnips, and 1,714 more pounds of hay, than the Hereford; but the Durhams, notwithstanding the larger size when put to fatten, and the greatly larger quantity of food consumed, sold for only twenty shillings more than the Herefords; and such I believe will ever be the result of similar trials, when one class of animals has been properly fed, and the other overfed, the merits of the breed being equal."

This reasoning is true in regard to perennial vegetables—trees for instance. If the nursery from which they are drawn, and in which they have been raised, is very rich, they will not thrive so well in a common soil, as those which are taken from a soil of an inferior quality. If the habit of gormandizing is established when the plant or animal is young, neither will thrive so well afterwards upon spare food, as if they have been brought upon more moderate fare.

From the Quarterly Journal of Agriculture.

EXTENDED USE OF MACHINES FOR SOWING GRAIN.

The extended use of sowing-machines, both drill and broadcast, will most probably supersede in a short time the practice of sowing grain by the hand. We own we should not like the idea of abandoning this ancient practice, though for nothing else than for the many pleasant associations by which it is endeared to every lover of field labor. These associations can never be recalled whilst using any sort of machine. Hand-sowing is also an accomplishment, and confers a superiority on the possessor. The season of the year in which it is most usually practised, inspiring the mind with the lively hope of a manifold produce; the measured step marking the time, and reminding of the progress of the work; the simultaneous action of the limbs, inducing the regular exercise of the muscular frame; the steady eye directing the flight of corn with a rainbow-like sweep to its destined place in the earth: all these tend to interest the sower in the continuance of the operation. Sowing by the hand, too, is a quick operation, one man keeping two pairs of horses, two men, and a woman in constant occupation. In this respect it is doubtful that machine is cheaper than hand sowing. It is, however, a difficult art, and can only be exactly performed after much practice; and as a proof of the difficulty of its acquirement, there are many men who never become neat, expert, and safe sowers all their lives. Being thus a difficult operation to acquire, and at all times performed with much labor, machine-labor will no doubt supersede it on all large farms, and, indeed, on all farms on which the grass-seed sowing-machine is used. The precision and beauty with which the broadcast sowing-machine distributes the grass-seeds on the ground, in all states of dry weather, in comparison with the hand, and the easy adaptation of that machine to the sowing of corn, has already substituted it for the hand on many farms. The quantity of seed to be sown can be regulated with much greater precision by any machine than by the hand. Besides, the broadcast-machine, the drill-machine, we perceive, is now much in use on the borders, particularly in sowing wheat. There are various sizes of those drills, but all are formed for the same purpose, and on the same principles. Their object is to deposit the seed at a given depth in the soil, and cover it up so as to require little harrowing afterwards. There is a practice of drill-sowing in Cumberland and Dumfriesshire, which deserves imitation in other districts. A person brings a large Suffolk drill from Suffolk, and undertakes to sow the autumnal wheat with it, at 2s. per acre. This is a very efficient implement, and as it costs £40 when new, employing it in this manner seems a very good plan of getting the wheat seed sown. The annual interest and tear and wear attending the ownership of this drill, would be equivalent to the sowing of twenty-four acres of wheat land. It is generally believed that drill-sowing saves seed. Whether the saving is an object, appears doubtful from the following statements of Lord Western, in a letter to Lord Rayleigh, dated from Felix Hall, in last March. He addresses his lordship to inform him "of the result of a mode of wheat sowing, which differs from the practice of this neighborhood, and which I have tried eight or ten years with great success, and the advantages of which are peculiarly striking this year, when the failures of plants are so prevalent. Any person now may have ocular proof of it. I can show them 100 acres of wheat, upon every acre of which I have a sufficient plant—I may say a full and thriving plant upon 90 of the 100. It is a nice question at all times to determine cause and effect, but I have no doubt in this case that the superiority of my wheat plant to most of my neighbors this year (which will generally be admitted by them) is owing entirely to my mode of putting the wheat into the ground. I use the drill in rows, nine inches apart, and put in at least three bushels per acre. I adopted the plan in consequence of what I saw at Holkham about eight or nine years ago, and from the strenuous advice of my friend the Earl of Leicester, and the example of himself and several of his very intelligent and experienced farmers, who joined him in urging me to this course. One old farmer, who occupied a very large farm under him, told me he had uniformly pursued that system above fifty years with the greatest success; he was of opinion that the quantity of seed was generally too small (of course the quantity should vary according to circumstances,) but he was satisfied an increase of seed would increase the growth of the country most essentially. Since that time I have sown all my wheat in this manner, and I have had great crops, I may say quite equal to the best farmers around me. I by no means ascribe these large crops of wheat exclusively to this drill system, because the seasons have been so good, and I have farmed high. I confidently believe, however, that something is due to the system, and that this year has shown that great advantages are derivable from it in seasons, and under circumstances that are unfavorable for the preservation of a good plant—the first object of every practical farmer, particularly on heavy land, whereon are so many failures. The general objection to the plan is, that the wheat will be thick in the rows, that it will grow up without tillowing, and with many short ears. I do not, on experience, find this objection well founded. I think the number of short ears to be found in this mode is not greater than in the wheat that has more room to tillow, and they are generally filled with good corn, full-sized grains. I hardly have heard any other objection made, and the advantages of the thick plant are many, some rather peculiar to this country. One considerable difficulty we have to encounter in our clay-bottom lands arises from the tardiness of our early vegetation, which renders our early plants comparatively a more easy prey to vermin of every sort, such as the slug, the worm, &c., and bad ungenial weather. Where there are any rabbits, destruction will often ensue in these lands from the weakness of growth in the plant, which would be overcome in warmer and quicker vegetating grounds. This remark of course does not apply to gravel-bottom lands, which are to be found in some few and limited districts. Now, it will be admitted generally, that where the plant is thick, it will grow considerably quicker upon first coming out of the ground—the numerous blades seem to protect and keep each other warm; and the roots partly matted together, get a better hold of the ground, so that they are not loosened by the biting off the blade, nor are they so loosened by succession of frost and thaw; they are by no means so likely to be root-fallen, which is productive always of the worst consequences when it occurs, and the mischiefs of which are peculiarly striking in many instances this year. I can drill with the heavy Suffolk drill, covering ten feet or twelve furrows at a time; nearly if not quite as straight as is practised in the light land of Norfolk and Suffolk."

We were glad to observe the prevalence of ribbing with the small plough the seed-furrow for spring wheat or barley on a winter ploughed furrow. There is no better mode of obtaining a fine mould, a good depth of bed for the seed, and of avoiding the bringing up of a raw clod which the ordinary plough would inevitably do in a late or damp season, and of dispensing with much harrowing. This ribbing is applicable to all soils, and particularly to those which are apt to throw out in severe frosts and bright sunshine in spring.

From the New England Farmer.

NOTICE OF THE CHINESE TREATISE ON SILK CULTURE.

[The following article, from a late English publication, relates to the curious old Chinese treatise, of which a translation has recently been published, and from which an extract was republished in the 4th number of this volume. These remarks will not be uninteresting to those who have read that extract; and may induce others, who have passed it over, to return to it, and give it due attention.—ED. FAR. REG.]

Not very many years have elapsed since the project of introducing the silkworm into this country was seriously taken up by several scientific persons; and the probability of its becoming eventually a source of wealth was warmly discussed. Gradually, however, the ardor of these projectors was found to cool, and the matter fell to the ground; and was soon as little spoken of, as if an enterprise had been meditated which sensible men ought to disavow. Notwithstanding this implied reflection on the good sense of the supporters of the plan, a few gentlemen shortly after might be found scattered through England, who still cherished the conviction that the introduction of this insect was perfectly feasible. They planted mulberry trees and bred silkworms as an innocent source of amusement; and to this day they continue to occupy their spare time in trying experiments on a limited scale, on the best modes of bringing up their favorites; but if the project was eagerly received here, in Ireland it was hailed with enthusiasm as a certain mode of realizing a fortune. The ardent imagination of the Irish easily overleaped the barriers which inexperience or want of capital threw in the way; and for any one not to have implicit faith in the silkworm speculation, was looked on as a mark of meanness of spirit, or of total disregard to personal advancement. A joint-stock company was even proposed, and a vast number of names were marked down for shares; but when the day of paying the first instalment came round, the absentees were found to be so abundant, "that the company dissolved itself," as a wag afterwards remarked, "even before it was formed." The zeal of individuals was but little manifested in mulberry plantations or silkworm nurseries. One person only showed that he had been perfectly serious in his enthusiastic advocacy of the enterprise; he planted some thousands of the trees, and when we passed through some dozen or fifteen years ago, we saw the plantations in a most flourishing condition. The Earl of Kingston it was who had given this proof of his being serious in the silkworm project; and even to the last, we believe he spoke with every appearance of being thoroughly persuaded of the possibility of the plan. Both in this country and in Ireland, the great objection was that the climate was too severe for so delicate an insect as the silkworm. The slightest variations of cold and heat were known to affect it; and sudden changes were frequently found to cause its destruction; modern discoveries have proved this notion to be hastily assumed, and perfectly erroneous. The insect is now known to be capable, with proper management and due precaution, of supporting our climate; and it is with the intention of showing the truth of this important fact to our readers, that we have determined to lay before them some valuable information which has but lately come to light.

The source from which we derive this information, is a treatise by the Chinese themselves, which has been lately translated and given to the public in France. When we consider the acknowledged advancement of the Chinese in the arts and sciences, evidenced by their knowledge of printing—of the mariner's compass—of gunpowder, and many other curious discoveries, long before the inhabitants of Europe, it is a matter of wonder that their literature has not been more carefully studied, and the results of such studies made public. All that we have until lately known of the Chinese, and their habits, manners, customs, and knowledge, has come at first through the early missionaries, and next through the embassies sent over from this country. A third spring of information has now been opened; and we are not over sanguine, in predicting that a most important stream of curious knowledge will be found to flow from it. Should it be asked, how it happens that this particular juncture has had the merit of making public the contents of the Chinese work, we answer, that it is the same cause which, in the days of Perseus, caused the Roman parrots, when hungry, to salute their mistresses in the Greek words they had been taught, namely, self-interest, a most prolific source of research and invention. Thus it was that the work was translated.

The production of silk, at the present day, in France, amounts to a value of more than 60,000,000 francs a year; which is, however, quite insufficient for the consumption, as the foreign trade alone reaches 50,000,000 francs a year. Silk is one of the principal products of China: for not only is it used to a great extent in the fabrication of their clothes, but a vast quantity is exported in the raw state, as well as in the shape of fabricated articles. For forty centuries have they devoted their attention to study, in its minutest details, the rearing of the worm which furnishes them with this source of their national wealth; and as a natural consequence, this long experience, always stimulated by the sense of self-interest, has caused them to discover a crowd of attentions, of proceedings, and of practices, most likely to procure for them certain and advantageous produce.

The missionaries were at once struck with the importance of these practices to the European cultivator of the silkworm; and they determined to mark down some of their modes of treatment, for the benefit of their countrymen. Two treatises were drawn up, and afterwards published in France. One of them, by Father d'Entrecolles, gives the extract of an old Chinese work respecting the treatment of silkworms; and the other, composed by Father d'Incarville (or rather, from notes left by him,) describes the treatment given to three other species of worms, which the natives designate "wild silkworms," because their nature requires that they should be permitted to live at full liberty on the trees from whence they take their food. Some of the methods of treatment described by d'Entrecolles, were not long ago put in practice by M. Camille Beauvais, a large breeder of silkworms at Senart. He found them to be most serviceable, and most certain and faithful in their results; but above all, he found that the adoption of the Chinese treatment was of wonderful efficiency in preventing accidents, which before had dreadfully puzzled and annoyed him.

As the abridgment of a work is always incomplete in details, M. Beauvais thought that it would be important to have the original Chinese work translated. He applied to the Minister of Commerce on the subject, and laid before him the importance of the case. M. Passy was at that time minister; and he applied, in his turn, to M. Stanislas Julien, as the first Chinese scholar in France, or perhaps in Europe. He directed this eminent *savant* to undertake the task; and M. Martin (du Nord,) who succeeded to the ministry of commerce, made the work complete, by desiring M. Julien also to translate the Chinese work on the culture of the mulberry tree, which is always annexed to the work on the treatment of silkworms. M. Julien undertook this arduous task; and has just given to the public a translation of the two treatises, of rare precision and clearness. To this has been added, Father d'Incarville's treatise on the wild silkworms; and the whole has been published at the royal printing office. The French scientific men speak of the work as containing a vast quantity of useful details; and they declare that it will be the means of greatly increasing the wealth of France. Without going the whole length of their sanguine anticipations, we can see that the information thus given is highly important, and that it may be of great value to this country as well as to France. One peculiarity of the work is, that the Chinese have followed no fixed plan; there is no succession of ideas in natural logical order in the Chinese writings. Down they put whatever thought occurs to them; satisfied apparently, like the sibyl of old, with having marked it down, but totally regardless of its fate afterwards. It might be a curious question to discuss the reason of this want of order; whether it arose from habit, or from some defect of organization: this, however, is beside our present purpose; we only desire to speak of the works before us. In considering them, it will not be found an easy task to place all in proper order. The little treatise by Father d'Entrecolles will be found of use as a sort of guide; but as it may not be practicable to obtain this work, we purpose culling from the translations some of the facts which strike us as useful and singular.

The silkworm, when it has just burst into life, is at first a little black caterpillar, about the length and thickness of an ant. In this state, its growth is so rapid, that after twenty-five or thirty days it has arrived at a size some hundreds of times more considerable. It then spins its cocoon, and is transformed into the chrysalid form; it emerges from thence a gay butterfly, engages in the work of generation, lays its eggs, and dies. The care of the Chinese follows the insect in all the phases of its short existence, without losing sight of it a single instant. The rapidity of its development as caterpillar, requires that it should several times get rid of its skin, and replace it by a larger covering. Every one of these changes constitutes a perilous crisis in the insect's existence; because it then remains without movement, and as if benumbed, during the period that nature urges on her handiwork.

It is easy to conceive, that the temperature, the food, and treatment, ought to be different for the insect when approaching its state of torpidity, from those which are most beneficial to it when in its time of health and vigor. The first and grand provision, therefore, for successfully rearing a season's insects, ought to be, to obtain a collection which, born at the same time, and under the same circumstances, shall be endowed with constitutions of like vigor, in order that the changes of their activity, of their torpidity, and of their final transformation, shall arrive simultaneously or nearly so. It is almost impossible to picture to one's self the multitude of cares which the Chinese devote to this fundamental condition. They commence their attention in the very choice of the butterflies destined to produce the eggs, rejecting such members of the two sexes as are born amongst the first or the last, and making use only of the intermediate ones; and even using their discretion in putting together, for the work of generation, those insects which their experience shows them are best suited to each other. Next the eggs become the objects of their solicitude. Here also they cast away the first and the last which are produced; and they pay great attention to having the batch equally distributed over the paper on which they contrive that the laying should take place. They thus avoid all heaping of the eggs, which would, when the hatching was concluded, place the insects in unequal circumstances; or if the eggs should, notwithstanding their precautions, be heaped on each other, they reject the mass altogether as intelligible for their purpose. Afterwards, they preserve these eggs with a thousand precautions, causing them to undergo various washings and other preparations, before the moment when the insect is about to burst into life.

So great is their ability in managing the education (if we may so term it) of the silkworm, that they generally contrive that all the insects should come from the eggs in the same day. Here again they reject the precocious and the tardy ones, in order to retain and bring up only those of the middle class. Having procured the fulfilment of this principle of original simultaneousness, they make every exertion to maintain all the phases attendant on the insect's existence. The cleverness of the Chinese is such, as to enable them to reduce the period of these changes, at most, to twenty-five, or even twenty-three days: whilst our unskillfulness obliges us to prolong the period to thirty or thirty-five days, to the serious detriment of the silk produced; for the Chinese have ascertained this important fact to be true, that the quantity of silk produced by the worm, is less in proportion to the length of time that it remains in the caterpillar form—the longer it remains, the less is the produce; and the rapidity of the reduction is enormous. To make this position clear, let us suppose that a number of worms, which have been developed in twenty-five days, have given twenty-five ounces of silk; if they remain, through any want of nourishment or necessary care, in the catterpillar state for twenty-eight days, the amount of the silk produced will not be more than twenty ounces: and should they delay to the thirtieth day, not more than ten ounces will be given. This is not only a very curious fact, but of great importance in a commercial point of view, and well worthy our serious attention. The Chinese have been long aware of it: and hence they deem no care too great which will hasten the birth of the insect. We must also look with admiration on the minute and delicate attentions with which they regulate the insect throughout. They are particularly cautious never to detach the eggs from the papers on which they have been deposited, to place them in heaps, as is so unreasonably practised in France, but they leave them their separate station and their hold on the surface, both which are found to be favorable to a speedy hatching. They also take care never to handle, or even to touch with the end of a pair of pincers, the little worms when they are born, in order to place them on the mulberry leaves: they would fear to run a risk of tainting them. How different is the practice in Europe, where it is quite a matter of daily occurrence to detach the eggs from the paper and place them in heaps: afterwards they are tied up in linen and transported to a distance. May not this be the cause of those frequent malformations which appear in the European silk nurseries, and which occasion such tremendous losses afterwards? a circumstance, be it observed, never seen amongst the Chinese. Their practice is, to gently place on the leaves the papers on which the worms have come into existence, in order that they may of themselves descend and take their food; nor do they place within their reach entire leaves at first, but little morsels, cut very neatly and scattered through a small sieve, in order that they may be distributed uniformly and in proportion to the number and the age of the worms. The quantity given at each repast is exceedingly small; and the increase is made in the number of repasts, but never in the mass of food given at each. The practice, we may remark, is founded on just principles; and the proofs of its efficiency are seen every day in our farms in this country, where cattle are found to thrive best on small and frequent repasts; not only because such are most easy of digestion, but because the animals eat more eagerly, and with a better relish, their food, when fresh, than trampled on, or tainted by their breath, when given in large quantities.

It would be an endless task to follow the Chinese through all their minute details, the influence of which, however, must be exceedingly great on the silk produced. Their treatment of the cocoons—their proceedings with regard to their silk crop; and their mode of winding the thread, are exceedingly curious. Our limits will not permit us to delay much longer; we shall, therefore, only add an interesting fact or two before we close. The Chinese use two sorts of artificial food for their silkworm; one of these is a leaf of a tree called *tche*, and a plant which bears the title of *Ouo-kin:* these are employed when the mulberry tree has not yet pushed forth its leaves, or when there is a scarcity of them. What these two productions are we have no means of ascertaining; that they are used throughout China for silkworms is certain, for mention is made of them in an old Chinese almanac, apparently intended for the working classes. The *tche* tree is also noticed by d'Entrecolles, who describes it as a prickly tree, which grew on exposed and lofty situations, and had a fruit like pepper. In the work translated by M. Julien, a rude sketch is given of the tree; but so vague is the outline, that we are unable to assign it to any particular class. The same incertitude exists as to the *Ouo-kin.* Remusat identified it with the wild chicorry; while in the *Amœnitates Exoticæ* of Kœmpler, it is suggested that it resembles our lettuce; it surely will be worth while to try both plants, and judge by the manner in which the silkworms receive them. The Chinese also employ, in feeding the worms, mulberry leaves gathered towards the end of the preceding season; these they dry and reduce to powder; and having lightly sprinkled the fresh leaves, they scatter it gently over them. The worms are always found eager to feed on it; and one advantage of it is, that it can be used at all times. Rice is also found to answer. It is first husked and then boiled by steam; this is then ground, and the flour is given to the worms. A small sort of pea, after being first allowed to germinate a little, is also employed; and all these preparations are said to render the silk stronger and more abundant. All these expedients are favorable to the introduction of the silkworm into England; which the Chinese mode of treatment proves to be perfectly practicable.

The long experience of the Chinese has made them aware of the fact, that the artificial education of silkworms requires a succession of different temperatures, suited to the different changes of their existence; and that, at the same time, the air which they inhale ought to be constantly purified of their perspiration, their evacuation and the bed of leaves on which they are placed. To effect this, they have found it necessary to erect close buildings, where an artificial increase or diminution of heat can be given when required, and where fresh air is constantly admitted. They have also discovered that these transitions of temperature must be almost insensible; and all their skill and ingenuity are taxed to accomplish this desirable object.

The Chinese author enters into a most minute description of the structure, materials, and situation of a silkworm nursery. He gives an account of the mode of heating it; and, at great length, details the form and use of the different instruments and utensils required in the concern. We do not intend following him in these details, curious as they certainly are; we shall only mention one circumstance connected with the heating of the nursery, which will show to what extent their cares are given. In addition to their scientific modes of maintaining the exact temperature beneficial to the worms, they employ what they deem the best indicator of a proper equilibrium, and even superior to a thermometer—this is the woman who takes care of the worms, and who is called their *mother.* This personage is clad in a single thin vestment, in order that her sensibility to cold or heat may be constantly awakened. These women are considered persons of importance; and whether from organization or habit, can at once detect the slightest change of temperature.

It is owing to this judicious use of air and light, (which we should have mentioned is particularly dwelt on,) that the Chinese are quite ignorant of those dreadful epidemics caused by mould, which in France makes its appearance on the bodies of the worms, in even the best regulated nurseries. In Italy also it is a matter of notoriety, that a vast quantity of worms perish every year from a similar disease; it is to be hoped, that from the present time the evil will be materially diminished. The best plan of a nursery yet tried in France, is one designed and erected by M. Darcet for M. Beauvais, of whom we have already spoken. This plan is considered, by some cultivators of silkworms, as most efficient; while others declare that it is little superior to a common workshop. The Chinese treatise shows that in many respects it is founded on wrong principles; and we may soon expect to hear that some modifications in its structure have taken place.

From what we have stated of the contents of the Chinese treatise, it may be seen that the cultivation of the silkworm is perfectly easy in this country. The difference of climate has been deemed by some scientific men as an insuperable bar; but this objection is taken away by the work which establishes the fact, that the greatest produce of silk in China takes place in the central provinces, lying between 25° and 35° of north latitude. Thermometrical observations have also proved that the mean temperature of the northern and southern provinces of China differs but little from that of Provence in France, the winters being somewhat more severe, and the summers a little hotter. The work also shows, that the cultivation of the silkworm was carried on to an enormous extent in the most northern provinces of of China, and we have no reason to suppose that the cultivation has been discontinued. Nor is it at all necessary that these silkworms should be reared in vast quantities or in large buildings; if this was necessary, how could the Chinese peasants pay their taxes, which are generally given in silk? The population of the country being exceedingly great, the land has been for ages divided into very small holdings; indeed, to this cause only can we attribute the declaration of Barrow and other travellers, that the appearance of the country is rather that of a vast collection of gardens, than that of an agricultural district. The philosopher Meng-Tsu, who lived in the fourth century before the Christain era, says, "that of the portion of land allotted to each family, it is sufficient to plant the twentieth part with mulberry trees, to enable the family to clothe themselves;" and since then, the tax imposed on each peasant's family is generally paid by a certain number of bushels of grain, a fixed quantity of silk stuffs, and some ounces of silk thread. This proves incontestably that each family rears worms to clothe themselves, as they cultivate the fields with their hands to feed themselves. Hence we may reasonably infer, that the methods prescribed in the Chinese treatise are equally applicable to private nurseries on a small scale; indeed, we might go much further and say, that the great establishments are exceptions, rather than the cottage of the husbandman; for as the work was drawn up for the general instruction of the nation, can we suppose that the writers had not in view the circumstances and condition of those for whom the work was intended? And as the vast majority of the inhabitants are of moderate means, ought we not to believe that the work was chiefly written for them, rather than for rich capitalists possessing large establishments?

We feel convinced that this branch of industry can easily be introduced into this country; and we do not deem the day far distant, when it will prove a source of wealth to thousands. Should our remarks lead to this desirable result, it will certainly be a source of great gratification to us; should we fail to excite public interest, we shall still have the consolation of thinking that we have faithfully discharged our duty.

CHINESE OPINIONS AND PRACTICES IN MULBERRY CULTURE.

[The few short extracts which follow, are from the Chinese work referred to in the foregoing article. In the enumeration and description of the various kinds of mulberry tree, it will be perceived that not one resembles the *morus multicaulis*, commonly called the Chinese mulberry.—Ed. Far. Reg.]

Different kinds of mulberry trees.

1st. The small mulberry trees (dwarf trees) have long branches, called *niu-sang* (ladies' mulberry trees) and *i-sang*. [*Eul-ya* Dictionary.]

2d. The *yen-sang* or *chan-sang* is the wild mulberry tree, the mountain tree. [Same work.]

3d. The *tseu-sang* or seed mulberry tree; its fruit shoots out before its leaves. [Japanese Encyclopedia, book LXXXIV, fol. 1.]

4th. The mulberry tree called *khi-sang* (that is to say, chicken mulberries) have leaves veined with red; they are rather thick. The silk worms that are fed on them produce a thin cocoon, which furnishes little silk. [*Tchong-chou-chou.*]

5th. The white mulberry tree bears thick leaves, that are as large as any one's hand. The cocoons of the worms that are fed on them, enclose a strong and abundant silk. This leaf furnishes twice as much silk as that of the ordinary mulberry tree. [Ibidem.]

6th. The mulberry tree, of which the leaves are plaited, and covered with a yellow pellicle, is called *kin-sang*, or the gilded mulberry tree. All the silkworms cannot be fed on the leaves of this tree, of which the color foretells that the tree will soon dry and perish. [Ibidem.]

There are some mulberry trees that do not produce fruit; they are vulgarly called *nan-sang* or male mulberry trees. [Japanese Encyclopedia.] The mulberry trees, of which the fruit sprouts out before the leaves, necessarily bears very few leaves. [*Tchong-chou-chou.*]

To sow mulberries, the fruit of the black mulberry tree of *Lou* must be taken. The yellow mulberry trees of the country of *Lou* cannot be preserved a long time. [*Thsi-min-yao-chou.*]

The mulberry trees of the country of *Khing* (ancient name of the province of *Hou-kouang*) and of the country of *Lou*, may be planted in level plains, where the ground is limey and clayey, and also in light earth. If the ground touches a mountain or hill, that is hard and mixed with red veins, it is only suitable for the mulberry trees of the country of *Khing*. [*Nong-sang-yao-tchi.*]

The different kinds of mulberry trees are very numerous, we cannot describe them all.

The best are those of the country of *Lou*, and of the country of *Khing*. The mulberry trees of *Khing* yield a great quantity of fruit, but those of *Lou* very little. Those of which the leaves are thin, pointed, and divided in lobes, are the trees of the country of *Khing*. They bear solid and hard leaves.

The mulberry trees of the country of *Lou* have round, thick, and juicy leaves.

The mulberry trees of which the branches and leaves are large, and thick, are a species of those of *Lou*.

The mulberry trees of *Khing* have solid roots and full hearts; they last for a long time. Those are the kind to be planted.

The mulberry trees of *Lou* have less solid roots, and hearts not so full; they cannot last for any length of time, (dwarf mulberry trees.) Trees called *ti-sang* are formed from them; but the trees of *Khing* have neither as many branches, nor as many leaves, as those of *Lou*. Branches of the mulberry tree of *Lou* may be grafted upon them; they then live for a long time, and yield an abundance of leaves.

If the mulberry trees of *Lou* be employed to obtain the species of tree called *ti-sang*, (dwarf trees) and if they be reproduced by twigs, they propagate without interruption, and last an infinite time.

The silkworms that are fed with the leaves of the mulberry trees of *Khing*, produce a firm and strong silk; it is fit to make *cha* and *lo-cha*, (kinds of thick gauze and crape.)

The leaves of the mulberry trees of *Lou* agree with the worms that are large; those of the trees of *Khing* with the small worms. [*Nong-sang-thong-khiouè.*]

—

Propagation of mulberry trees.

The work entitled *Thsi-min-yao-chou*, describes the manner of obtaining the best seed of the black mulberry trees.

The two ends of the mulberry must be cut off with a pair of scissors, and only the middle part taken. The seed of the two extremities are comparatively smaller than the others, and if sown they produce little mulberry trees, called *khi-sang*, (chicken mulberry trees) and *hoa-sang*, (flowering mulberry trees.)

—

The intermedial part of the mulberry has larger and harder seed. The trees that proceed from them have firmer and stronger branches, and they bear thick and nourishing leaves. [*Nong-sang-thong-khioué.*]

—

The mulberry trees called *ti-sang* (dwarf trees) ought to be planted in a garden near a well. If grass springs up around the roots of the trees, the earth must be turned up with a spade. When it does not rain they must be watered. When the silkworms are hatched they ought to be watered three times a-day; the leaves will then grow very quickly.

Among the different kinds of mulberry trees there are some that sprout out early, others late. It is from among the mulberry trees which are in leaf the earliest, that those are chosen, from which the trees called *ti-sang*, or dwarf mulberry trees, are formed. [*Nong-tching-tsiouen-chou.*]

—

In the work, entitled *Tchong-hoa-min*, it is read: There are two kinds of mulberry trees: one bears the fruit of which we sow the seed: it sprouts out in the first or second month, (February or March.)

The following is the manner the other kind is multiplied:

A pliant branch is bent to the ground, and maintained in that position by a clod of clay. Each bud produces a branch. When this mulberry tree has attained the height of two or three feet, its roots are then formed. The mother branch to which it belongs is then cut, and it is transplanted in another place. It soon becomes a tree. [Same work.]

* * * * * * *

Observations upon the choice of mulberry plants.

The mulberry with a wrinkled bark yields only small and thin leaves; those of which the bark is white, the joints long, and have large buds, are the leafy trees of *Chi*, (diospyros; they always bear large and thick leaves. The cocoons spun by worms fed on them are firm, and furnish a great deal of silk.

The tall white mulberries succeed well upon the declivity of hills, in the angle of a wall, or by the side of a hedge.

The mulberry trees of less height, with a black bark, should be planted in moist ground. [Same work.]

The mulberry trees with black bark, which produce no seed, when the leaves are not too thick, are good for the nourishment of newly hatched silkworms. (Same work.)

The trees of the country of *Wang-haï*, are multiplied in the same manner as those with the white bark. The tree called *thsé-teng-sang* (or mulberry tree with rose-like branches) grows high and strong.

The white mulberry tree, or the tree with white bark, yields very little seed, it is multiplied by layers. If a person has seed they can sow it, but it must be in the shade. Heavy well filled cocoons will be formed, which will produce twice as much silk as the ordinary ones. [Same work.]

* * * * * * *

Manner of pruning large mulberry trees.

The branches must be thinned, and above all, pruned in time. It ought to be done in order that the branches may acquire strength and push early, and that the silkworms may not want leaves.

If the branches are cut off, those that remain will acquire strength, and the leaves will become thicker and more nourishing. If this year they are pruned at the proper time, the long branches will become strong and vigorous; the leaves of the next year will shoot out early, and they will be thick and glossy.

All the branches from the centre must be cut, so that a man may stand up and easily make use of the axe. The branches and leaves fall outside of the tree; that is much better, than to be obliged to remove all around the tree a heavy ladder. A man thus placed in the centre of the tree, can do as much work as two persons placed outside of the tree. Too many branches must not be allowed to grow, otherwise they cannot be cut without hard work; moreover, the leaves will be thin and destitute of taste.

Moreover, the art of properly pruning the mulberry trees, is one of the most important points for the raising of silkworms. Many persons do not know how to make beforehand the necessary preparations when the cessation of agricultural work gives them leisure. They only occupy themselves with the mulberry trees, when the season of tending the silkworms has overloaded them with trouble. In this manner they are overcharged with double work, and often the silk worms want necessary nourishment. If, on the contrary, these mulberry trees have been pruned, according to the rules, so that the branches can be easily reached, and the leaves obtained with facility, the silkworms will not wait for their food, the leaves will come in proper time, and, moreover, they will be thick and glossy.

The method used in the country of *Thsin* is called *lo-sang*. In the last month of the year, (January,) all the superfluous branches must be pruned away, and those that are left be much thinned; afterwards upon the branches that are preserved, four eyes must be left, and the others picked off. The next year the branches that were left will have become strong; the black twigs which will have grown from the middle of the eyes will be three feet in length; the leaves will be twice as thick as usual, and will present a smooth and brilliant surface. During the raising of the silkworms, they can be gathered with the hand; the external branches only, that shoot forth, must be left. After having grown luxuriantly, until the autumn, they will have obtained the length of eight or ten feet. In the last month of the year, (January,) they must be again pruned, as before. After the expiration of several years, if the branches that have been left appear to overload the tree, they must be pruned at their base.

This method is followed in the country of *Lo-yang*, to the east of the Yellow river; but a different mode is adopted north of this river, in the province of *Chan-tong*.

When the mulberry tree has attained the height of five to seven feet, from the period of its transplantation, the tops of the branches must be cut. As the branches of the centre have been removed, those that remain will grow in a horizontal direction, and extend outward. When the tree has become large and strong, a man can stand up in the centre.

When the tree has attained its *maximum* of strength and growth, the stalk and the branches must be cut in the centre.

There are three kinds of branches that must of necessity be removed.

1st. The branches inclining towards the root;

2d. Those which bend inward, towards the trunk;

3d. Those which grow in pairs; one must be cut;

4th. Those growing in a good direction, but which are too thick and too bushy.

The last month of the year, (January,) is the most favorable for pruning: the month that follows is less so. In the last month of the year the sap is quiescent, and the cessation of labor in the country leaves much leisure to the cultivators. Those persons who prune in the spring, only do it in order to peel them easily, (to make paper,) but that causes the mulberry trees to lose a great quantity of sap.

Those persons who wish to make use of the bark of the mulberry tree can take the branches, cut in the last month, (January,) and deposit them, with a southern exposure, in a hole, covered up with earth. They must be taken out in the second month, (March,) and they then peel very easily. [*Nong-sse-pi-yong.*]

From the Farmer and Gardener.

THE SILK CULTURE IN NEW JERSEY.

To the Editor—I have been spending a few days in the ancient city of Burlington; and as far as my observations and inquiries enable me to form an opinion, I should say that this was the head quarters of the silk culture in the United States. I have visited several places, whose fame in connexion with the advancement of this branch of industry, has been spread far and wide—and I have often been obliged to make diligent inquiries, before I could ascertain, *on the spot*, that any thing was doing at said places. But Burlington does not hide her light under a bushel: she places it on an eminence, so that all may see, and peradventure imitate her good works. You cannot pass along the pavements, without hearing questions asked about silkworms or mulberries: you can scarcely go into a house but you find the inmates engaged in feeding worms. All classes and conditions, from the dignified functionary of the government to the humble occupant of a village lot—rich and poor—publicans and sinners—have caught the contagion: and recently even a periodical—and a most respectable one too—has been established to promote the culture, and disseminate all useful information on the subject. And if you knew the character of the population here, you would say that the good work must succeed. You would be far from thinking it was the ebullition of the moment—a feverish paroxyism—a day dream; which would subside on the slightest abstraction of the stimulus which now supports and sustains it. Such, I take it, is not the character of this people. On the contrary, they are grave, sedate, industrious—not given to violent and momentary excitement—not liable to be entrapped, and inveigled by designing men, into speculative pursuits; but a people thoughtful and reflecting, forming their own judgments upon evidence, and when once formed, pursuing their object with an eye that does not slumber, and a wing that never tires. In this city, a large proportion of the population consists of the descendants of the illustrious Penn—remarkable, you know, for their industry, perseverance and neatness—and by the force of contact and example, these characteristics have been visibly impressed on all the surrounding population.

Gentle reader! who takest an interest in the progress of this interesting pursuit, you might spend a few days here with both profit and pleasure. You will have all your inquiries answered without hesitation. You will find nothing enveloped in mystery. You will see every one willing and anxious to impart all he knows—and finally, I think you will be convinced that the silk culture is no humbug.

POWHATAN

Burlington, 3d July.

From the Burlington Gazette.

THE MORUS MULTICAULIS.

It is known to the public, a considerable distance round Burlington, that large quantities of this most invaluable tree are now growing in the vicinity of this city. A larger quantity would have been raised the present year, but for the cold wet spell of weather which occurred at the planting season, causing numbers to rot in the ground; this was succeeded by a drought of three weeks' duration, accompanied by intensely hot weather, producing effects decidedly more injurious to the young sprouts, than the cold damp which preceded it. From these causes the crop of trees is very far short of what was expected. The plants which survived these disasters, are now growing with a luxuriance of foliage that realize to the mind by a single glance of the eye, the sterling value of the multicaulis for the production of silk. It is true that different modes of planting, and a different course of cultivation, have produced different *quantities* as well as different *qualities* of trees, some having succeeded better than others. But from the stock of trees now growing, it is certain that the short supply will be more than compensated by the high prices they will command. There can be no doubt that trees will sell higher the coming fall and spring than they have ever done yet. The character of the multicaulis is now well established in the middle states, from practical acquaintance with it, and it has lived uninjured, in the open fields of Burlington, during the whole of the past winter. As its value becomes better known, the demand for it increases from all parts of the United States. The high bounties on the production of silk which are given by the states of New Jersey and Pennsylvania, have been found sufficient to pay all the expenses of producing the cocoons and of reeling the silk, making the whole produce clear profit. This fact, when added to that of an acre of ground planted with trees two years old, producing a net profit of $300 to $400 per annum, has stimulated the farmers in various sections of the middle states to embark largely in the business of planting trees for the sole purpose of raising silk.

From notices we have read in our exchange papers, of nurseries in various places, an impression appears, to exist that all the trees now growing throughout the country are *for sale*. Nothing could be more contrary to the fact; and those persons who expect to make large purchases of trees this fall, will find themselves greatly mistaken. Some growers in our neighborhood could not be induced to sell at *any* reasonable price. We know one instance of a company which intended going into the business last spring, with a stock of 30,000 trees, being compelled to begin with about 5000 only, such was the impossibility of getting trees. Of all the trees now growing, probably but one-third are raised for sale—full two-thirds being grown to feed the worms. So far as the business has progressed in Burlington, it has answered every expectation that was formed of it. Very great profits have been realized from small lots of ground, and there is every prospect of our ancient city becoming the emporium of American silk.

SELECTION OF SEEDS.

The August No. of the Southern Agriculturist contains an editorial general notice of the contents of the July No. of the Farmers' Register, with the kind and approving tone of which we have reason to feel gratified, and find no exception to that feeling in the following comment upon our (alleged) heterodox opinion, and the vain attempts to defend that opinion from the attacks of assailants. We have often enough, in these volumes, readily confessed mistaken opinions, to free ourselves from the charge of holding obstinately to any, for the purpose of maintaining a claim to consistency. An agriculturist, more especially than other men, who never changes his opinions on the subjects of his profession, must necessarily remain as ignorant in the end, as his "consistency" would show him to be narrow-minded in the beginning; and one who does not frequently change his views of the relative advantages of practical details, must profit very little by investigation and by experience. It may be supposed, that the farmer or the politician who changes his opinion, is at least wiser than he had been before; and we have never valued the virtue of consistency of opinion so much as to defend our claim to it, if our brother editor had correctly understood and reported either our first declaration, or the alleged "unsaying of it." We shall not here repeat again at length what we have several times stated; but merely refer to all that has been said on this subject, to show, 1st, that we did not in any sense "venture a sweeping condemnation of those who look for profit in the selection of seeds;" and 2d, that we maintain now, as stoutly as before, that the *principle and manner of selection* which were condemned are worthless.

The following is the passage referred to:

"The Editor ventured a sweeping condemnation of those who look for profit in the selection of seed; he is met by one of his correspondents on the question, which it seems has two sides, and the strongest against him. Our unhappy brother finds himself involved in the necessity of unsaying his rash opinion; while he insists upon his consistency as sturdily as a politician who may happen to prefer the reputation of far-sighted wisdom, to a frank confession of mistake. The examples of benefit from the selection of seed, are too numerous and too familiar to daily observation, to leave a doubt that much depends upon it. Sometimes the opinion has been placed in unnecessary contrast, with the acknowledged advantage of an occasional change of seed from one climate or kind of soil to another. Which is productive of the greatest good, is not very easily determined. But there is no very plausible reason why both means of improvement should not be combined. For example, corn very fruitful in ears, or bearing ears of an extraordinary size, may be simultaneously cultivated in situations distant and differing from each other, and mutual exchanges profit both parties."

CAPONS.

To the Editor of the Farmers' Register.

Hanover, August 4, 1838.

Sir—Your last number has just arrived; and I see in it a communication, from some one who signs himself "Rusticus," in regard to capons. He says that he has never seen one in this country, and that every person of his acquaintance, who has attempted to make them, has failed. Now, there are living near me some young men who raise great quantities of fowls, and who, for their amusement, have performed the operation on several young cocks, and have succeeded in every instance but one, and that failure was owing to the bird being too large.

The capons are a good deal larger than a cock, their plumage, I think, much richer; and it is really a beautiful sight, to see half a dozen or so of these fine-looking birds in a flock. They take no notice whatever of the hens, are very cowardly, and have a cluck similar to that of a setting hen.

These gentlemen let me know, about a year ago, the day on which they would make some of them, and I went down, and found the operation a very simple one, and was able to do it myself, after having seen some two or three operations performed. After the next communication of "Civis," if his method does not agree with mine, I will let you have my *modus operandi.*

S. R. M.

From the Farmers' Cabinet.

HOW TO FORM A JUDGMENT OF THE AGE OF A HORSE BY HIS TEETH.

At two years old, the horse sheds the two middle teeth of the under jaw. At three years old, he sheds two other teeth, one on each side of those he shed the year before. At four years old, he sheds the two remaining, or corner teeth. At five years old, the two middle teeth are full, no longer hollow, as all the others are, and the teeth have penetrated the gums. At six years old, the four middle teeth are full, the corner teeth only remaining hollow: the tusks are sharp, with the sides fluted. At seven years old, the corner teeth are full, the tusks longer and thicker, and the horse is said to be *aged.*

Note. It is not meant that exactly at the periods above mentioned these changes take place in the horse; much depends upon his constitution; whether he be a late or early foal; also upon the manner in which he has been reared, as to food and shelter, &c. The corner tooth, too, might remain a little hollow after the age of seven, but the appearance is still very unlike the mere shells, which they are, at the age of six.

COMMON SCHOOL LIBRARIES.

[It will be seen, by the following article, that the legislature of New York has made an appropriation for common school libraries, upon the large scale of munificence and liberality, and enlightened regard to public interests, for which that great state has been distinguished, and by which wise course of policy it has already so eminently profited. New York is a *great* state, not so much by the natural advantages of her territory—great as these are—as by her wise and liberal legislation, for nourishing and sustaining education, agriculture, and all the important interests of the people. When shall we see the legislature of Virginia making even the tithe of the magnificent grant of that of New York, in the purchase of facilities for popular instruction, or any other mode for diffusing information, for the benefit of the agricultural community?

But while applauding the act, in general, its object and its tendency, we concur heartily with the editor of the 'Cultivator,' in preferring that the *subjects* of the books furnished should be very different. It is unnecessary here to repeat, in another form, the views presented to our readers in our recent remarks on the propriety of the state's furnishing agricultural books for the primary schools, (pp. 263-4); as all then said, if the case were applicable to Virginia, might as well be brought to bear on the libraries, as the ordinary school-books, for common schools. We are glad to have this indirect support of the editor of the 'Cultivator' thus given to our views. If his own excellent agricultural periodical were made to form so large a proportion of the school libraries of New York, as to be placed in the hands of every otherwise destitute boy, who is to be a tiller of the soil, it would be worth ten times the other value of the proposed libraries, and far more than the whole amount of the money appropriated for the annual purchases.—ED. FAR. REG.]

From the Cultivator.

We were unadvised of the fact, until we saw it announced in a late Jeffersonian, that the legislature made an appropriation at its last session, of $45,000 per annum, for three years, for the establishment of common school libraries. We fully concur in the sentiments expressed in the following extract which we make from the Jeffersonian, as to the salutary influence which this judicious appropriation is likely to have in enlarging the sphere of useful knowledge, and in improving the condition of the producing classes of the community.

"We trust no friend of the great cause of universal education, no parent, no youth, no lover of his country, has forgotten or will forget the provision so wisely made by our last legislature for the establishment and support of *common school libraries.* We feel a proud satisfaction in contemplating the fact that New-York stands forth in this matter a pioneer and a glorious example to her sister states. The law making provision for the distribution of the annual revenue of the new common school fund, (arising from the deposit of the late surplus revenue with the states,) appropriates forty-five thousand dollars a year exclusively to this beneficent purpose. Each district in the state is entitled to draw its share of this fund, proportioned to the number of its scholars; and, estimating the whole number of districts at forty-five hundred, this sum would allow an average of ten dollars to each district, or thirty dollars in the course of the three years' duration of the law. We believe this estimate is rather under than above the truth; and that, with a very moderate display of public spirit on the part of the people, a very comprehensive and most useful library may be immediately secured to every school district in the state.

"The great advantages of this noble enterprise, to that very large proportion of our citizens who are unable to buy large collections of books, cannot be over-estimated. Not alone to children and youth will its benefits be dispensed. Parents and others of mature years can readily avail themselves of the fund of useful and instructive reading, which is thus brought to their doors. Even should the library consist of but fifty volumes at first, each family in the district may draw one volume from it per week for the whole year, returning it at the week's end for another; and thus enjoying a supply of information and entertainment for the whole period without the cost of a cent. At the end of the year, a new instalment of the appropriation will be doubled, and another year's reading commenced. We firmly believe that in this way the library will be found a great auxiliary to the school, by creating a new interest in its management and its welfare. Should the district conclude to have a little gathering every Saturday evening, or some other evening, to exchange books, or return and draw again, a lyceum, or association for mutual improvement, would soon grow out of it, and still greater benefits be realized. Each parent and scholar would feel that he had a personal interest in the library, as well as the school; and thousands would spend their leisure hours in reading, which would otherwise be given, almost of necessity, to frivolous, if not corrupting amusements."

Thus far our quotation. But we are not prepared to go farther with the Jeffersonian—in its approbation of the selection of books designated and recommended as the *basis* of common school libraries. The Messrs. Harpers, to whom we accord great credit for their enterprise and industry, have printed, we are told, under the direction of the American Society for the diffusion of useful knowledge, a series of fifty handsome volumes, of uniform size and appearance, to be comprised in a neat case, and furnished at twenty dollars. These books, of which a list is given in the Jeffersonian, treat mostly of foreigners, foreign lands, and of matters foreign to the great pursuits of our country. They are the Lives of Bonaparte, Alexander the great, Peter the great, Oliver Cromwell, of celebrated travellers and female sovereigns; ancient and modern Europe, the Holy Land, the Crusades, Arabia, the Chinese, voyages, travels, &c. We see but eight volumes that seem from their title to relate particularly to our continent, and but about the same number that are written by Americans. But we do not recognize one, among these books—which are designed almost exclusively for an agricultural community—we do not recognise a single volume on agricutural chemistry, or on agricultural botany, or on agricultural geology, or on the mechanics of agriculture, the great modern lever which simplifies, abridges, and at the same time augments the products and profits of human labor; we see nothing on the veterinary art, or the management of cattle—nothing upon practical agriculture or horticulture—and little, if any thing, upon the moral, relative and political duties of life. The studies to which we have last alluded, ought to form the foundation, the basis, of a rural education; those selected might become auxiliary, or supplemental; or, the two classes might be blended like brick and mortar in the walls of a building, to give beauty, as well as solidity, to the structure.

It needs no argument of ours to convince any reasonable man, that the proper study of youth, is the business which is to employ them in manhood. Thus we give to the law student elementary books in the business which is to constitute his living; and to students in divinity and physic, the elementary books suited to their several professions; and we require a four years' study in these elementary works, in order that the student may fully understand the principles upon which he is to preach or practice, before we permit him to put on the toga of manhood, and to take rank with his profession. And shall not the student of agriculture, whose business embraces a wider range of useful science than either of the before mentioned classes, be permitted, during his minority, to study the elementary principles of *his* profession?—to store his mind with the precepts and practices of eminent men in that profession? We say, lay the *foundation* in usefulness—in that knowledge which will tend to make intelligent, useful and contented farmers, and good citizens, of the boys of our common schools. You may then build whatever superstructure you please upon this solid foundation, and embellish it to your taste.

But we are reminded, that we are treading on hallowed ground; that the society for the promotion of useful knowledge, with Gov. Marcy as its head, have sanctioned the selection that has been made, and, as if to silence every doubt, that Gen. Dix, superintendent of common schools, has also given it his approbation. Without wishing to derogate, in the least, from the high character of the gentlemen who constitute the society, or to depreciate their efforts to do good, we must be permitted to doubt their pre-eminent qualifications for selecting a suitable library for an agricultural community. Most of the gentlemen, we believe, belong to the learned professions, or to the mercantile class; and we are willing to award to them a high standing in literature and general science; yet few of them, we apprehend, know much of the practice or theory of farming, a business which stands first on the roll of usefulness, and which it is the interest of every class of the community to enlighten and improve; and they are therefore not exactly best qualified to promote this great object of national prosperity, be their intentions ever so patriotic. Or at least so we are obliged to infer, from the catalogue of books which have been published. And as for our highly respected secretary of state, he is no doubt well qualified to select a law or literary library, or to thread the mazes of politics—yet we should not venture to trust him, with all his qualifications, to select *our* library, or manage *our* farm. Would these gentlemen trust an association of farmers, however intelligent, to select their *professional* libraries? We think not.

But perhaps we are going too far: something on agriculture is promised in the next series, and we ardently hope it will be furnished.

After all, it may be said, and will be said, and by thousands of farmers too, that agriculture wants no auxiliary aids; that it has done well enough, heretofore, without the aid of books or of science—and that it can continue to do so. How would such a remark apply to the other arts of labor? Look at the cotton factory for instance—a yard of cotton goods may now be purchased for half the price which was paid for barely *weaving* a yard thirty years ago. The manipulations in most of the other arts have been so abridged by machinery, and the processes so simplified by science, that the fabrics produced by these labors are greatly lessened in price. In these arts, the improvements of the age are speedily registered and promulgated in books and periodicals. Mechanics and manufacturers know how to appreciate this sort of book knowledge; and it enables them to keep pace with the improvements of the age.

Not so our farmers generally. They have little intercourse with each other; they have no access to agricultural books, and many are too old or too prejudiced to seek for or receive information. The consequence is, that we are making slow progress in agricultural improvement, while agriculture is being made to double, treble and quadruple its products upon the old continent. Youth is the appointed time, and the only time that can be relied on, for implanting the knowledge and the principles which should guide and govern in the business of manhood—and of laying the foundation for good citizens and intelligent, prosperous farmers.

From the Maine Farmer.

TO PREVENT DOGS SUCKING EGGS.

It sometimes happens that the *sometimes useful, and sometimes useless* animal called a dog, finds out eggs are very good eating, and takes the liberty to "lay his jaws" to every one that he meets with—taking, also, like some other servants, with not quite so many legs—the meat to himself, and leaving the shell to his master.

A friend of ours once had a "Bose," which he was very found of, and which was in most respects, a very sedate, worthy sort of a dog, but he had the trick of sucking every egg he could find.

Having heard that a dose or two of tartar emetic would make him sick of that business, he accordingly tapped one end of an egg, put in a lot of the tartar emetic, and laid it down in his dogship's path, who forthwith helped himself to its contents, without ceremony. He was then kept without water, and occasionally, from time to time, supplied with a *medicated* egg, till Bose began to find that the very sight of them was a signal for a fit of sickness, and wisely resolved to quit the business, which resolve he kept, as a good and faithful dog should. If you have a "good for nothing dog," and he sucks eggs, shoot him. If you have a good dog and he sucks eggs—*doctor* him.

MANURING IN SOUTH CAROLINA. MARSH GRASS, MARSH MUD, AND LEAF-LITTERED COW-PENS.

Extract from the Address of Joseph E. Jenkins, to the Agricultural Society of St. John's.

All animal, vegetable, and many mineral substances, may be converted into manure. With the two first we are most conversant; the last has not yet sufficiently occupied our attention, with perhaps the exception of salt, which, as a component part of the marsh mud, has been long and successfully used. Some of our members have, within a year or two, used it in its raw state, but the results have not yet been sufficiently satisfactory, nor the trial sufficiently extended, that we should at present dwell upon them. On those gentlemen, we may with confidence rely for statements at the proper time. The manure most commonly in use amongst us, is vegetable, decomposed in our cow-pens, where leaves of trees (principally of the pine) are dunged upon and trampled by the cattle. It is the common usage of this section of country, to lay by, or more properly speaking, leave off working the growing crop at or about the tenth day of the present month, (July), after that period, it is considered by some of our best planters as rather hazardous to meddle with, as any new excitement, by stirring the earth around the root of the plant, which would cause a new growth, would at the same time cause a disastrous falling of the young fruit or capsules. We may consider it, therefore, as a pretty general rule, growing out of experience, (that best of teachers,) at this period as most advantageous to go to something else, and that something else is the collection of manure. We are bountifully supplied with all the requisites; the leaves of the pine appear to be prolific for the especial purpose of furnishing us with an excellent substance for our use. The borders of our rivers, which are numerous, intersecting our islands in every direction, abound in a highly nutritious marsh grass, of easy access, of a tender stalk, very convertible into muck manure. A few months' trampling, either in the cow-pen or stable, renders it a mass the most powerfully stimulative of any manure with which we are conversant, so much so indeed, as to have induced the belief, that its exhibition upon what is called table lands of a dark loam, has a tendency to cause the cotton plant to overgrow; and on lands impregnated with whatever substance it is that causes blue, to fall more certainly, and to run into vines. In this state, its product is beggarly indeed. I have seen portions of cotton fields, whose product was not a solitary pod.

Marsh mud is our next important material. This substance is abundant to superfluity, and the experience of every planter on this Island, with the exception of one or two, has sustained it as highly advantageous and profitable. Its tendency is to render loose lands more tenacious—to restore the original stamina to worn out or exhausted soils, causing thereon the stalks to hold the fruit, as in its virgin or original state, but it has been doubted whether it has a direct action in producing luxuriance of vegetation. This is a matter of little importance, and I shall not stop to consider it. There is a remedy, if it is so, which the very nature of the location points out emphatically to our view—this is simply a combination of the marsh grass with it. To effect this, two years ago I commenced the following process—eight fellows were furnished with scythes to mow down the marsh [grass;] eight more placed in boats and flats, to gather up and convey it to a place of deposit at the margin of the river. They thus conveyed each day sixteen cords, or a cord a piece for each hand employed. Day by day we did this, from Monday morning to Friday night, depositing along the margin of the river, within the reach of the high tide, consecutively, each day's cutting. On Saturday, at low water, all hands upon the plantation, both these and others, let their employment be what it may, were called, and with hand-barrows, covered the whole surface of the marsh with mud, from one to one and a-half foot thick. The weight of the mud compressed, and held firmly in its position, the marsh under it—the tide at high water passed through the compressed marsh, hastening wonderfully the process of decomposition, and at the time when it was taken up in the spring to be conveyed upon the land, it had (that is the marsh) a black look, as if ready to be resolved into its original elements. The hoes with which it was cut away, passed through it with peculiar ease and facility, as much so almost, as if it had been all mud. This process of making manure, recommends itself on several grounds—first, its entire and perfect mingling, and thereby meliorating the condition of each of two substances, the one thought dangerous from the excess of strength; the other held useless by some for the want of it. Secondly, the saving of extra carting to the cow-pen, to be trampled as in the usual way—and thirdly, the great facility with which they are brought to the place of deposit. I have seen the negroes, when cutting on the side of the river where the heap was to be made, leaving the boats, collect into great masses the cut marsh, and getting behind them, push up an immense quantity to the shore with the greatest ease. With the mixture thus collected last summer, I manured this spring fifty-nine acres, at the rate of forty loads to the acre, which I hold to be as profitable an investment of the work of sixteen hands for two months, as well can be made, being at the rate of three acres and three quarters to the hand.

The making of cow-pen compost, with pine trash and other leaves, was effected by the women. The light trash was raked up and placed at the edge of the woods, whence the trash carts conveyed it to the pen. Here I would remark upon the advantages which result from the proper structure of the trash carts. An entire body of light stuff, in open lattices, should be so fixed up at the sides and back, as that a two ox wagon should hold a cord of pressed leaves; two oxen in proper keep, will, with apparent ease, draw this much. These useful animals, patient and sturdy, require in the summer much care and attention—an inhuman driver, inattentive to their wants, will soon destroy them. They cannot work long without water; they require immeasurably more than either the mule or the horse to sustain them—but with this requisite properly attended to, they can perform from their superior strength, although slow of gait, almost as much work as either. The primest fellows, therefore, and most industrious, should be detailed for this service, otherwise time will be idled away in the morning, which to regain, the animals will be overworked in the afternoon, and thus suffer much maltreatment and abuse. Drivers of oxen should never be indulged in carrying large sticks in their hands; a small switch, or a thong of leather fastened to a handle, is quite sufficient, for these docile and tractable animals easily learn the word, and are as well so directed, indeed better, than by the most severe blows that can possibly be inflicted. Their yokes should be light, with the haimes or bows fitting tight around the neck; by allowing them to be too loose, they play upon the working of the shoulder blade, and inflict dreadful wounds, lacerating the skin in a shocking manner, and incapacitating the animals for the performance of one half their labor. With regard to the application of manures, that must mainly depend upon the previous state of the lands on which they are to be used. The usual quantity allowed to the cotton crops, is from twenty to thirty loads of compost to the acre, and from forty to eighty of marsh mud, but it is seldom that these extremes are reached, more commonly the lesser than the greater. The apprehension which, when we first commenced manuring, I heard expressed by some, that manuring would in the long run prove more injurious than beneficial, has I think entirely subsided. I presume there is not within the sound of my voice, I may say indeed within the bounds of this parish, a planter who would now be willing to subscribe to such an opinion. Like other schemes of improvement, it at first had its opponents, but like all useful innovations, it has outlived to detraction. Could I learn the name of the first man in this parish who made a compost pen, and had I it within my power, his fame should be spread abroad, and his name be immortalized; for he has rendered to us an inestimable blessing, and far be it from any one to withhold his meed of praise.

From the Farmers' Cabinet.

WHAT IS THE GREATEST QUANTITY OF MANURE TO BE OBTAINED FROM GIVEN MEANS.

Mr. Editor—There are in agriculture, as perhaps in every science, some leading propositions, calculated in a particular manner to arrest attention by their prominent importance. Such I hold that of a "Subscriber" in your May number—"*What will an acre of land produce?*" and also the question which heads this article.

Were it possible at once to afford a complete and palpable solution to these two propositions, what mind can calculate the vast increase of treasures that would instantly become accessible to humanity? As then, we cannot inquire too strictly, or know too much regarding them, I propose, after recapitulating a few of the principal statements of a "Subscriber" concerning the latter question, to furnish my own experiments upon the former.

He informs us that a single acre of his land, *with abundant manuring and superior cultivation,* was made to produce the sum of $348 40 cents per annum, for five successive years, besides the vegetables used in a small family. He further states in substance, as his present convictions that the quantity of soil cultivated has nothing to do with the secret of gathering money out of it; that "this altogether depends on a judicious selection of soil, *on the facility of obtaining manure;* and on the proper application of it as food for plants," &c.; that he found, by actual experiment, made upon a large scale, "that the profit of capital laid out in land produced an interest of only *five* per cent. per annum, the capital laid out in manure upon the same land produced *twenty* per cent."

Now, my own experience, as I shall presently show, abundantly confirms the probable accuracy of all these statements. Let us distinctly understand, then, that it is not the great quantity of land, but *the abundance of manure* upon a little, that is alone required to give wealth and independence; that the man who owns five or six acres may, (according to the above data,) with the aid of manure and good management, draw from $1,800 to $2,000 from them each year, while he of a hundred acres may scarcely obtain half of it upon the common plan.

But where is the requisite manure to be obtained that shall so suddenly and surely enrich the farmer? In reply to this, I will simply give my own experience, and by it endeavor to convince the reflecting farmer what amount can, and in fact *has* been made from means incomparably more limited than is generally imagined possible.

Previous to 1829 I had followed in Philadelphia a sedentary occupation, which, by excessive application in it, had so enfeebled my constitution, that I was obliged to seek in the country for that measure of health which I might no longer hope for in the city. So I bought, with my scanty savings, a small place of ten and a half acres, and moved upon it the same fall, of 1829.

Not being acquainted with farming, I hired a man to plough two and a half acres, and sow it in rye. The cost of seed and labor, in putting in, gathering, and thrashing the said crop, was $8 56 cents. The crop yielded five and a half bushels of very poor black rye, fit only for hay feed—say at forty cents per bushel, (as good rye was then selling at fifty-six cents per bushel,) was worth $2 02 cents, and the net loss sustained upon farming the ground was $6 36 cents. The season was moderately good for grain, and the two and a half acres rather a favorable specimen of the rest of my land! I planted a potato patch the following spring (1830,) of about one-fourth of an acre, which I manured in the hills with one load of marl only, and the crop yielded but three and a half bushels!

Being a total stranger to the nature and character of soils, but having previously, from some cause, entertained the notion that land in general produced about twenty-five bushels of wheat, or forty bushels of corn, or four or five loads of hay to the acre, the conviction I had now received of the absolute worthlessness of my land fell upon me like the shock of a thunder-clap. Discouraged by the greatness of my disappointment, but not quite confounded, I determined that manure, in future, should be every thing to me, and stand in the stead of both land and crop. Being greatly improved in health, by the change of situation and exercise, I plied my avocation with increased diligence for the maintenance of my family, and made it the amusement of my leisure hours and leisure moments to collect from every corner, and pannel of fence, every thing that I imagined could furnish a vegetable nutriment, and placed it in my cow-yard, so combined with the litter as to absorb and retain every thing of a putrescent character that might be deposited there. By such means I have gone on, every year increasing the quantity of manure, to an extent that I believe has astonished most of our neighbors. The following is a sketch of the means I possessed, and the methods I took to obtain manure for the present year.

I commenced last summer by collecting into the outer part of my hog-pen every thing of the weed kind I could find about the place, till I had a layer about twelve inches deep, which I covered with a layer of earth about five inches thick, continuing the process till the pen was filled to about two and a-half feet deep. In the fall I littered my loose corn-cobs and the principal part of the buckwheat straw into the pen, interspersed with layers of earth in the same manner. The two stalls of my stables I served also the same, taking care to save therein all the chaff and refuse straw after thrashing. In these stalls I poured weekly, through the fall and winter, (for I had no cattle in them except in bad storms,) the soap-suds and such putrescent fluids that might be obtained, keeping the corners, and outsides, and under the mangers, carefully saturated.

As soon as my corn was gathered in the fall, I cut the stubs close to the ground, and wheeled them immediately, *while yet heavy*, into the barn-yard, where I packed them in every part of it, and also under the shed, being an area of ground about forty feet by twenty, and in a few days covered them also with a layer of earth, from a fence-row close by, to the depth of about eight or ten inches. Upon this earth I foddered my cattle during the winter, occasionally depositing more earth upon the litter as it collected there.

Your readers will readily judge, that the object of all this preparation was not so much for the sake of saving the materials collected there as to obtain a menstruum, or rather *sponge*, if I may so call it, calculated to absorb and retain all the urine deposited in the yard during the winter. The compost masses, however, or layers, thus collected together, are not to be considered as manure prepared for the soil, but only as *materials* that require to be thoroughly *mixed*, in order to reduce them to a state fitted for a rapid and complete incorporation with the soil. Accordingly, with this view, I commenced late in April the operation of turning it, which, from its having become closely packed to the depth of twenty inches, with the stalks at the bottom, could only be done with the aid of a grubbing hoe, turning it in strips about a foot wide, reaching across the yard, and throwing the loosened manure back a sufficient space to allow a trench between, wide enough to work in. After removing the whole cover from the stalks along a strip, as before mentioned, they were easily grubbed up, first cutting them through all along the solid edge of the strip with the hoe, it being made pretty sharp for the purpose. In addition to this pile of yard manure, I have also emptied the contents of my hog-pen and stables, extending the pile several feet, and lying upon the ground, when first loosened, more than two and a half feet deep. Of this manure I have used sixteen loads this spring, for truck and garden, and, judging from the size of the pile yet remaining, there cannot be less than sixty loads, which, being turned once more, I intend to use for wheat next fall.

In this manner, from only three head of cattle, and the fattening of four hogs, I have made from seventy to eighty-two horse loads of manure, the highly fertilizing properties of which are abundantly attested by my own former experience. I will not say that it is stronger than the best barn-yard manure, but from its closer affinity to the nature of the soil, and greater facility for being rapidly combined and incorporated, without loss by evaporation, I have no doubt it will be frequently found, upon trial, more effective and more durable.

In the process of turning manure, thus prepared, I hold it of the highest importance to mix well the earthy and vegetable parts together. Few persons are perhaps aware how rapidly the earth facilitates vegetable decomposition, and to what a surprising degree *it absorbs the excess of fertilizing effluvia*, which must otherwise be evaporated during the process of decomposition. This circumstance, I believe, taken in connexion with the careful economizing of all animal excretions, constitutes chiefly the great secret (I might, perhaps, add *alleged* necromancy,) that has added already so much verdure to my previously exhausted soil, and been so profitable to me, and so surprising to my neighbors.

No farmer can imagine, that has not tried the experiment, what a prodigious quantity of rich, vegetable, and fibrous earth may be collected from corners and by-places, which lie out of the way of cultivation, and which, from their retired position, have, perhaps, never so much as attracted his notice. All such refuse trash, and fibrous earths and weeds, by being conveyed to his barnyard, at intervals, during the fall and winter, and judiciously combined with its contents, will be converted into a rich, fertilizing, and durable manure, merely by absorbing and retaining *that excess of putrescent fluids and effluvia*, which is otherwise lost by filtration and evaporation; that is, by soaking away and drying up. W. H.

Pittstown, Salem Co. N. J., May 20th, 1838.—

From the Farmer's Series of the Library of Useful Knowledge.

FLEMISH HUSBANDRY.

The poor sandy heaths, which have been converted into productive farms, evince the indefatigable industry and perseverance of the Flemings. They seem to want nothing but a space to work upon; whatever be the quality or texture of the soil, in time they will make it produce something. The sand in the Campine can be compared to nothing but the sands on the sea-shore, which they probably were originally. It is highly interesting to follow, step by step, the progress of improvement. Here you see a cottage and rude cow-shed erected on a spot of the most unpromising aspect. The loose white sand blown into irregular mounds is only kept together by the roots of the heath: a small spot only is levelled and surrounded by a ditch; part of this is covered with young broom, part is planted with potatoes, and perhaps a small patch of diminutive clover may show itself: but there is a heap of dung and compost forming. The urine of the cow is collected in a small tank, or perhaps in a cask sunk in the earth; and this is the nucleus from which, in a few years, a little farm will spread around.

In another spot more extensive improvements are going on; a wealthy proprietor or lessee is trenching and levelling the surface, sowing broom-seed, and planting young fir-trees, which are to be cut down in a few years. In another, the process has gone on further, the firs or the broom are already cut down: a vein of loam has been found, and is dug out to be spread over the sandy surface: the cart with liquid manure is preparing the surface for the reception of seed, or the same, diluted with water, is poured over the young blade just appearing above ground. The soil is created, and, if the cost and labor were reckoned, is paid for at a dear rate: but perseverance insures success, and there are few instances of improvements being abandoned, after they are fairly begun, unless they were undertaken on too large a scale; but then the land is soon divided into smaller portions, and improvements go on from different centres, and with more certainty.

We are here describing the labor of bringing a soil absolutely barren into a state of cultivation; but in most of the districts which have been originally waste and covered with heath, and which are now fertilized, a less ungrateful soil was found. Deep trenching and levelling at once presented a surface which required only to be manured to produce rye, flax, and potatoes. This is what we should call a moderately good sand, in which a small portion of clay and oxide of iron produces a certain degree of compactness, so as at least to retain moisture: under this kind of sand a stratum of loam is usually found at the depth of two or three feet, and, almost invariably between the sand and the loam, an indurated crust of earth cemented by carbonate of iron, which is well known to all improvers of poor sands by the name of the *iron pan:* this pan must be broken up and the loam under it mixed with the sandy surface, before any cultivation can succeed; and in this operation the Flemings are very dexterous. The instrument they use is a light wooden trenching spade, the end of the blade only being shod with iron: the handle of this spade is about two feet long, the blade from twelve to fifteen inches. A light pick-axe is used to break the pan where it appears. A ditch is dug with the trenching spade, two or three feet wide, and as deep as the trenching is intended, generally two feet, or at least twenty inches; this ditch is filled with the earth which is taken in long thin slices from the edge of the solid side of the ditch. Every slice is distributed carefully, so as to mix the whole, and keep the best soil at top, and likewise to fill up hollows and level eminences. If there is more than can conveniently be spread level, little heaps are made of the superfluous earth, which are afterwards carried, in an ingenious manner, to fill up more distant hollows, by means of horses and an instrument which is called a *mollebart*. Wherever there is a pan, it is carefully broken, and the loam, which is always found under it, is mixed with the sand dug out. Draining is seldom required here, except that which is effected by making deep ditches to carry off the superfluous rain-water, which, in a country almost as level as a lake, is no great difficulty. A canal near at hand is, however, an essential condition of extensive improvement, to bring manure, and carry off the produce of the land, as well as to be an outlet for the water in the ditches. When Count Chaptal traversed a barren part of Flanders, accompanying the Emperor Napoleon, the latter expressed his surprise, at a meeting of the Council of the Department, that so great a tract of land remained uncultivated in so industrious a nation. The answer was, "If your majesty will order a canal to be made through this district, we pledge ourselves that in five years it will be all converted into fertile fields." The canal was ordered to be made without delay, and in less time than they promised not an unproductive spot remained. (See Chaptal, "Chimie appliquée à l'Agriculture," vol. i. p. 347.) One great cause of the agricultural prosperity of Flanders is the ready transportation of manure and produce by canals. But to return to the newly trenched land. If there is no manure at hand, the only thing that can be sown on poor sand, at first, is broom: this grows in the most barren soils; in three years it is fit to cut, and produces some return in fagots for the bakers and brickmakers. The leaves which have fallen have somewhat enriched the soil, and the fibres of the roots have given a certain degree of compactness. It may now be ploughed and sown with buckwheat, or even with rye without manure. By the time this is reaped some manure may have been collected, and a regular course of cropping may begin. As soon as clover and potatoes enable the farmer to keep cows and make manure, the improvement goes on rapidly; in a few years the soil undergoes a complete change: it becomes mellow and retentive of moisture, and enriched by the vegetable matter afforded by the decomposition of the roots of clover and other plants. It is surprising that so few sheep should be kept on these new farms. Sheep folded would do good by their tread, as well as their manure, but the management and feeding of sheep is a part of husbandry in which the Flemings, with very few exceptions, are decidedly as much behind our light land farmers, as they are before us in the feeding of their cows, and preparation and economy of manure.

If about twenty small cart-loads of dung can be brought on each acre of the newly trenched ground, the progress is much more rapid. Potatoes are then the first crop, and generally give a good return. The same quantity of dung is required for the next crop, which is rye, in which clover is sown in the succeeding spring; and a small portion is sown with carrots, of which they have a white sort, which is very productive and large in good ground, and which, even in this poor soil, gives a tolerable supply of food to the cows in winter. Should the clover fail, which sometimes happens, the ground is ploughed in spring and sown with oats and clover again. But if the clover comes up well amongst the rye stubble, it is cut twice, after having been dressed with Dutch ashes early in spring. It is mostly consumed in the green state. The clover-ley is manured with ten cart-loads of dung to the acre, and rye sown again, but not clover. After the rye comes buckwheat, without any manure; then potatoes again, manured as at first, and the same rotation of crops follows. It is found that the poor land gradually improves at each rotation from the quantity of dung used: and, as this is essential, it will be easily seen that without water-carriage the improvement could not go on: for the necessary quantity of dung could never be brought to the ground by land-carriage through the deep sandy roads, which are mere tracks.

For want of sufficient manure, broom-seed is sometimes sown with the rye after the clover. The rye is heaped and the broom continues in the ground two years longer. It is then cut for fuel. The green tops are sometimes used for litter for the cows, and thus converted into manure. It is also occasionally ploughed in, when young and green, to enrich the land. Oats, clover, and broom are occasionally sown together. The oats are reaped the first year; the clover and young broom-tops the next, and the broom cut in the third. This is a curious practice, and its advantage appears rather problematical. All these various methods of bringing poor sands into cultivation show that no device is omitted, which ingenuity can suggest, to supply the want of manure.

After the land has been gradually brought into a good state, and is cultivated in a regular manner, there appears much less difference between the soils which have been originally good, and those which have been made so by labor and industry. At least the crops in both appear more nearly alike at harvest, than is the case in soils of different qualities in other countries. This is a great proof of the excellency of the Flemish system; for it shows that the land is in a constant state of improvement, and that the deficiency of the soil is compensated by greater attention to tillage and manuring; especially the latter. The maxim of the Flemish farmer is, that "without manure there is no corn—without cattle there is no manure—and without green crops and roots cattle cannot be kept." Every farmer calculates how much manure he requires for his land every year. If it can be bought at a reasonable rate, he never grudges the outlay. If it cannot be purchased, it must be made on the farm. A portion of land must be devoted to feed stock, which will make sufficient manure for the remainder: for he thinks it better to keep half the farm only in productive crops well manured, than double the amount of acres sown on badly prepared land. Hence also he does not reckon what the value would be of the food given to the cattle, if sold in the market, but how much labor it costs him to raise it, and what will be the increase of his crops from the manure collected. The land is never allowed to be idle, so long as the season will permit any thing to grow. If it is not stirred by the plough and harrows to clear it of weeds, some useful crop or other is growing in it. Hence the practice of sowing different seeds amongst growing crops, such as clover and carrots amongst corn or flax; and those which grow rapidly between the reaping of one crop and the sowing of another, such as spurrey or turnips, immediately after the rye is cut, to be taken off before wheat sowing. These crops seem sometimes scarcely worth the labor of ploughing and sowing; but the ploughing is useful to the next crop, so that the seed and sowing are the only expense; and while a useful crop is growing, weeds are kept down. These are the general principles of Flemish husbandry.

* * * * * * *

The collection and application of manure is the great secret of Flemish husbandry. Upon their poor light soils nothing could be raised without an abundance of manure. It is, consequently, an object of minute attention to the Flemish farmer to collect as much as possible, and to apply it in the most advantageous manner. For this purpose the dung of the different domestic animals is generally kept separate, especially that of cows, from that of horses; the former being thought better for dry sandy soils, the latter for colder loams and clays. They look upon pigs' dung as being cold and inferior, adopting in this respect the opinions of the ancients. We think differently; but this may be easily accounted for. The Flemish store pigs are fed in the most miserable manner, and are merely kept alive on weeds taken from the fields, or by very scanty grazing in rough pastures. We need not be surprised, therefore, that their dung is poor. The cows are better fed, and their dung is consequently richer. Cow dung is thought to last longer in the soil, and its effects on the second crop are more conspicuous than that of horse dung, which stimulates more and is sooner effete. Sheep, which are so important to the light-land farmer in England and Scotland, for their manure, are not kept in sufficient quantities in Flanders, nor well enough fed to do much good to the land. They are commonly housed every night, and driven about in the day to gain a scanty subsistence along the roads and sides of the fields. The manure collected in the sheep-fold is carried out on the land, and its effects are duly appreciated. A flock is occasionally folded on a clover-ley before it is ploughed up, but never on the turnips, which are always given to the cows. This is owing to the small extent of the farms, which do not allow of a considerable flock of sheep being kept by any one farmer; but a flock is made up of different lots of sheep belonging to several proprietors, and put under the care of a common shepherd, or it is sometimes the property of the shepherd, who occupies no land, but lets out the sheep to fold, or sells the manure.

But the great auxiliary of the Flemish farmer is the URINE TANK, wherein are collected not only the urine of cows and horses, but also the drainings of the dunghills. The urine tanks are generally sunk below the level of the ground, and have the sides built of brick, and the bottom paved: they are of various dimensions, according to the numbers of cows and horses on the farm. Attached to the distilleries, where many beasts are constantly kept to consume the refuse wash, there are very large urine tanks of an oblong shape, divided by partitions into different chambers, so that the liquor may be of proper age when it is used, which some farmers think ought to be six months. Each chamber is about eight feet square and six or eight feet deep; these are sometimes vaulted over, but frequently only covered with loose boards. As urine and the emptying of privies are sold wholesale and retail, there are many large tanks near the rivers and canals, where the dealers have sometimes great quantities in store. Some of these consist of many square pits like tan-pits, bricked round, and the inside covered with a cement, which prevents loss by filtration. There is generally in a corner of each pit a graduated scale, by which the number of barrels, or tons of liquid in the tank may be ascertained by observing the height of the surface. These tanks are gradually filled by boat-loads brought from the large towns; and when the season arrives for sowing, in spring and autumn, the farmers come with their carts and tubs, and purchase as much as they may want. The price varies from three to five francs (two shillings sixpence to four shillings) per hogshead, according to the quality. In a small farm of thirty to forty acres the tank is generally about twenty feet long, twelve wide, and six deep, with a partition in the middle, and arched over, leaving an opening for the pump, and another sufficient to allow a man to go in to empty out the earthy deposit which falls to the bottom. A trap-door shuts over this aperture to prevent accidents. Sometimes the tank is round, like a well, with a domed top, and so deep in the ground, that it has a foot or two of earth over it. The situation of the tank is either in the farm-yard near the entrance of the cow-house, or immediately behind it; sometimes it is like a cellar under the building; but this is apt to cause a disagreeable smell in the cow-house. We here describe those which we consider the most convenient: the form and capacity of the tanks vary greatly according to the means and notions of the proprietors of the farms: but a tank of some kind or other is considered as indispensable an appendage to a farm as a barn or cow-house. The farmer would as soon think of dispensing with his plough as with his tank; and no expense or trouble is spared to keep this well suppled. The numerous towns and villages in Flanders afford great help in the way of manure. The thrifty housewife and her active substitute the maid, know the value of what in our households is thrown away or wasted and lost. A small tank, or a tub sunk in the ground in some corner contains all the liquid which can in any way be useful; soap-suds, washings of dishes, &c., are carefully kept in this reservoir, until, once a week, the farmer or contractor calls with his tub on a cart; and this, mixed with the contents of privies, which are frequently emptied, he keeps in large cisterns for use or sale.

But this supply is not always adequate to the wants of the farmer, and then he has recourse to rape cakes dissolved in water, or in the tank, which is expensive, and can only be profitable where flax bears a good price, this being the crop for which rape cakes are chiefly used as manure. Every means, therefore, of augmenting the supply of urine is had recourse to, and the most efficacious is the establishment of distilleries. These answer the double purpose of consuming produce and increasing manure by the number of beasts which are fattened on the refuse wash. It is calculated that every beast produces at the rate of ten or twelve tons of dung and twenty-six hogsheads of urine in the year. A moderate distillery has fifty or sixty head of cattle constantly stalled. Here then is a supply of manure for several hundred acres of land every year. Formerly there were a great many distilleries in Flanders, but the duty on spirits and the interference of the government has much reduced their number; so that the farmers complain of the loss of this manure, and the consequent deficiency of their crops.

The dung of pigeons and domestic fowls, where it can be collected in any quantity, is highly valued. The mode of using it is either in a dry and powdered state, to which it is reduced by thrashing with a flail, when it is sown with the seeds of leguminous plants, or else dissolved in the urine tank, and thus spread over the land. This manure is chiefly reserved for kitchen gardens; it promotes the growth of vegetables and produces no weeds.

The solid dung, from which the liquid has been allowed to run off into the tank, must be carefully attended to, that it may not be too dry and become *foxy*, as it is called, or burn. It is therefore mixed up with earth and any useless vegetable matter which can be collected into a heap or compost; and when it appears too dry some of the liquid from the tank is poured over it, to excite fermentation and accelerate decomposition, or it is merely watered, when there is sufficient strength in it to produce heat.

In order to increase as much as possible the quantity of solid manure, there is in most farms a place for the general reception of every kind of vegetable matter which can be collected: this is a shallow excavation, of a square or oblong form, of which the bottom has a gentle slope towards one end. It is generally lined on three sides with a wall of brick to keep the earth from falling in, and this wall sometimes rises a foot or more above the level of the ground. In this pit are collected parings of grass sods from the sides of roads and ditches, weeds taken out of the fields or canals, and every kind of refuse from the gardens: all this is occasionally moistened with the washings of the stables, or any other rich liquid; a small portion of dung and urine are added, if necessary, and when it has been accumulating for some time, it is taken out, a portion of lime is added, and the whole is well mixed together; thus it forms the beginning of a heap, which rises gradually, and in due time gives a very good supply of rich vegetable mould, or compost well adapted to every purpose to which manure is applied. The place where this accumulation is made is called in French a *croupissoir*, and in Flemish or Dutch *smoor hoop*, which may be translated *smothering heap*.

Besides the manure which is collected on the farm, the *vidanges*, or emptyings of privies obtained from the towns, and the sweepings of streets, a large quantity of peat ashes imported from Holland are used, principally as a dressing for clover. These are the ashes of the common fuel in use in Holland, and are sold in Flanders by the bushel, as the Newbury ashes are in Berkshire.

Wood ashes, after the greater part of the alkali has been extracted for bleaching, are still considered as of great use to the land. Soapers' ashes are in great request for cold heavy soils; and sugar scum from the refiners, if it could be procured in sufficient quantity, would be an excellent manure for every kind of soil. Where it can be obtained, they usually throw it into the urine tank; and the mixture is then considered as almost equal to the vidanges, which are looked upon as the *ne plus ultra* of manures. Soot is used as a top-dressing for wheat, or clover in spring, as it is with us. It is thought to destroy insects and hasten vegetation.

The weeds, which grow abundantly in all ponds, canals, and ditches in this level country, where the current is never rapid, are mown in spring, and used in the green state as manure for potatoes. They are laid in the furrows, and the sets placed over them; the furrow is then filled up by the plough, and the weeds decomposing very rapidly, greatly assist the growth of the potato plants: so rapidly do these weeds ferment, that much of their value is dissipated, if they are left only forty-eight hours in heaps before they are put into the earth.

The manner in which manure is applied to the land for different crops will be explained as these are separately treated of: but the general principle which pervades the whole system of manuring, is worthy of attention. Two great objects are always kept in view. The first is to obtain the most abundant crop of whatever is sown: the next is to impregnate the soil with an increasing power of production, if possible, or at least to maintain that which has been obtained. In consequence of this, almost every crop has a certain portion of manure applied to it, which varies according to the nature of the crop to be raised, and that which has preceded: experience having taught that some crops exhaust the soils more than others.

But it is not the mere surface that they desire to manure. They well know that the deeper the soil is fertilized, the greater will be the profit and the less the labor. They are not satisfied with enriching the land to receive the seed, they furnish food for the growing plant in different stages of its growth, if they think it necessary. There is in consequence no fluctuation in the growth, no check at a time when the plants require support. The seed is made to vegetate rapidly by being in contact with the rich juices of the manure; and hence a much smaller proportion of seed is required. The young blade is invigorated by a judicious watering, and is sooner out of danger of the attacks of insects.

Liquid manure is carried to the fields in common water-carts, which consist of two wheels and shafts, carrying a cask containing from sixty to one hundred and twenty gallons of liquid. The cask has in the under part a hole, two or three inches in diameter, secured inside by a valve: under this is a board a little slanting, to spread the liquid as it flows out of the cask. A man usually rides on the horse which draws the cart, and holds in his hand a string, which passes through a hole in the cask, and opens the valve when required. There is an advantage in riding on the horse, as it does not add to the weight of the load on the wheels, which in light soils would be apt to sink deep. In a momentary exertion it assists the horse by the weight on his back; and the heavy Flanders horses are well able to carry a man and draw a light load at the same time. When the cask is empty he trots home for another load, and no time is lost. It is astonishing what advantage there is in accustoming horses to trot when they have no load; it actually fatigues them less than the continued sleepy walk. Who would suppose that the Flemish and Dutch farmers surpassed us in activity? but whoever has been in the Netherlands in hay-time or harvest must acknowledge it.

The dung which is carried in a solid state, is generally used at a time when it is in a state of active fermentation, as it is then supposed to have the best effect. To ensure this in some districts, as the Waes country, where the minutest attention is paid to every circumstance which can increase fertility, the dung is laid on the field in moderate heaps, and on each heap a certain quantity of urine is poured to excite and renew the fermentation: when it becomes sensibly heated, the dung is spread out and immediately ploughed in. After ploughing in the manure, the land is left for some time, and then a second deep ploughing is given to incorporate the decomposed dung with the soil, but so as not to bring any to the surface. A short time before sowing, the liquid manure is poured over; and this enriches the surface to make the seed germinate sooner.

Lime is not much used in the light soils, but commonly in the cold and stiff. As it is generally brought from a distance, it is dear; and this prevents any extensive application of it. Marl is found in a few spots, and serves to improve the poorer lands within reach of it.

BONE MANURE.

In consequence of the extensive introduction of this new species of manure into our highly improved system of agriculture, thousands of acres that would have been doomed to nearly total barrenness have been brought under the most promising cultivation. As yet, the supply has not kept pace with the demand. It will somewhat surprise our readers, that, in the county of Forfar alone, 153,000 bushels of bones were used last year—a quantity which, at three shillings per bushel, would cost, as nearly as may be £23,000! This great supply came from Russia. But, for reasons not precisely known, the Russian government have issued an ukasé, whereby bones to be exported must, after the 1st of January next, pay a duty so high, that it is almost certain the supply from that country will be wholly cut off.—*Edinburgh Observer.*

From the Penny Magazine.

PIGEON-ROOSTS.

There is an extensive district of country stretching eastward from the head waters of the Ohio, through the northern parts of the states of Pennsylvania and New York, which, from the major part of the forest trees being beech, is known by the general appellation of the "Beechwoods." When there is a favorable season for the beech-tree bearing nuts, which is not always the case, the whole surface of the ground is strewn with them by the gales, about the period when the early snows begin to fall. The beech-nuts remain beneath the snow unmolested during the whole winter; about the time when the influence of the spring causes them to vegetate, myriads of pigeons are attracted to that part of the country, where they continue to sojourn, while this, their favorite food is in tolerable abundance. In case the temptation is exceedingly strong, the old birds will sometimes nest and breed again; the place they select being generally along some ridge or eminence, where the branches of every tree become literally loaded with their rudely-constructed nests. When the time of incubation is over, the neighboring settlers resort to the breeding-ground; and as powder and shot are expensive articles in the Backwoods, the woodsman's favorite weapon—the axe—is called into operation; such trees as are of a moderate thickness are hewn down, and hundreds of young and simple pigeons, some in the nests and others perched upon the branches, are brought to the ground. Bags and sacks are then put in requisition, and such as are of approved size are huddled by scores into those unsportsmanlike receptacles; whilst numbers of the rejected are left to perish by hunger, if they have unfortunately survived the concussion caused by the falling of the tree. When the parties get tired of "cutting down and picking up," and have got themselves and their horses (for many bring horses to those "pigeon frolics") pretty well loaded, they set out on an expedition of "pigeon peddling" among such as have either no time or taste to engage in this rude and barbarous recreation.

The breeding-ground is altogether distinct from the pigeon-roost; while the old ones are hatching their second broods, the young wanderers from the south are left to take care of themselves. Throughout the whole of the beechwoods there are low and swampy pieces of ground designated "Beaver Meadows." Those swamps, for the most part, are overgrown with tall coarse grass; and around many of their margins grows a profusion of alder bushes, seldom attaining more than fifteen or twenty feet. Why or wherefore the pigeons select those bushes for their roosting-places might be somewhat difficult to conceive, since the forest-trees in the immediate vicinity would afford them much greater security; but such is the case at present, and such it is known to have been.

Although the nests and their inhabitants are exceedingly numerous in the forests where they breed, yet the number of pigeons that roost in one of those "alder-swamps" upon which they chance to fix as a rendezvous, surpasses all belief. There are thousands and tens of thousands, and in some cases hundreds of thousands! and they are therefore so closely stowed together that they support and rest upon each other. The assailants, instead of going armed with guns, or even with axes, carry a pretty long pole or club, and a few dry pine-knots, to light up when they get to the roosting-place, not forgetting sacks wherein to deposit their victims. Having reached the pigeon-roost towards midnight, a light is struck, and the blaze of one or two of the pine-knots astonishes and confounds the unsuspecting occupants of the branches over-head. They move to and fro, they flutter, but do not attempt to quit the bushes, seemingly determined to retain possession of their roosting-place regardless of consequences. While one person holds the torch the other is busily engaged in dealing destruction; when in that particular place the ranks of the poor innocents seem somewhat thinned, the killed and wounded are placed promiscuously in the sacks, and in some other part of the roost the former scene is reacted.

Those torch-light excursions yield more than abundance to the adventurers; yet it generally happens that they resort by daylight to the scene of their nocturnal deeds, where they seldom fail to meet with scores of the dead and wounded birds they had overlooked in the hurry and darkness of the preceding night. It is exceedingly strange, that among the thousands of pigeons taken in the manner here described, there never happens, by any chance, to be any old birds! As soon as the second broods are capable of accompanying their parents in their onward journey to the far regions of the north and west, they all as with one accord, leave this section of country; for by this time their favorite food—the beech-nuts—is quite exhausted.

From the Southern Review.

ON MANURE.

Extract from an article on the "Principles of Agriculture," by Professor Thomas Cooper.

By a manure, in popular language, is meant any animal or vegetable substance added to the soil, which will undergo, or which has previously undergone decomposition by putrefying.

More accurately, manures comprehend any addition to a soil, by which it is rendered more capable of promoting the growth of vegetables planted in it.

Hence, a manure may act by altering the mechanical texture of a soil, *in relation to the roots* *of plants planted in it;* so as to enable them to take firm hold of the soil for support, or to penetrate more easily into the soil, in every direction that the roots may require. As when clay is added to sand, or sand to clay, to make it more or less adhesive.

A manure may also alter the texture of a soil, *in relation to its capacity for imbibing or retaining moisture.* The hot climate and long-continued droughts of the Carolinas and Georgia, require a different texture in this respect, from the moist and misty climates of Ireland, or the highlands of Scotland.

A portion of clay consisting of one hundred parts by weight, being wetted until no more water would drop from it, was found to have imbibed and retained two times and a half its weight of water: the same weight of chalk (carbonate of lime,) retained one half its weight; and the same weight of silicious sand, one quarter of its weight. These experiments made by Bergman, are cited by Mr. Kirwan, in his treatise "On Manures," (p. 45.) The experiments of Fabroni are to the same purpose. Hence, whether the first mentioned, or the last mentioned intention be required to be fulfilled, clay or marl is a proper manure for sand, and sand for clay, and calcareous earth for both. But the constituent portions of the various earths in a soil, fertile as to its capacity for retaining moisture, cannot be ascertained until very many facts and experiments have been observed and detailed, beyond what we know at present: and in relation also, not merely to the quantity of rain that falls in an average of years on a given place, but to the relative proportion of dry and wet weather on the average of a series of years. Thus, at Stockport and Manchester, in England, the yearly fall of rain will be about 36 inches, according to Dr. Percival, and the number of rainy days may amount to 234 in a year, as a friend of ours has counted. As many cubic inches of rain may fall in Charleston in a dozen days, as in the 234 days of rain in the neighborhood of Manchester; so that the expression of a moist and rainy climate, relates not so much to the quantity of rain that falls, as to the number of days and hours the rain occupies in falling. Fifty inches of rain per annum, with three months of drought, will not constitute a rainy climate.

Probably, five parts of silicious sand, three parts of calcareous earth, or carbonate of lime, and two parts of pure argillaceous earth, would be a mixture that might deserve to be regarded as fertile, as to the view now under consideration. The proposal of General Beatson to manure with clay baked in an oven, or half burnt, so as to be perfectly friable and pulverizable without losing its capacity for imbibing and retaining moisture, seems to us an improvement of no slight importance. Trusting to his description and calculations, we regard the expense as very moderate. So treated, the clay can be ground into a coarse powder, and intimately mixed with the soil which it is meant to improve.

Besides the ways and manners above mentioned, manures may be applied also to *stimulate the living fibres of the plant;* and they may be applied as a pabulum or food, *to nourish the plant.* Hitherto, in all the British publications on manures, they are considered either as acting mechanically, or by their chemical decomposition as affording the substances which are taken up as nutriment. Kirwan, indeed, "On Manures," (p. 48) seems to think that saline substances may act as condiments to plants; and enable them to take up more food. His excepting gypsum, arose from his considering this substance as a septic, a promoter of putrefaction in vegetables; and, therefore, as having no other action than what it exerted on the dead matter employed as a manure. Sir H. Davy, in his fifth Lecture, seems to think it necessary to combat the notion that vegetables are possessed of *life* in the same sense as animals; whose life he seems to consider as emanating from a superior immaterial principle. We shall cite the passage in a note,* and only observe upon

---

* *Elements of Agricultural Chemistry,* (p. 170.)—"It is impossible to peruse any considerable part of the vegetable statics of Hales, without receiving a deep impression of the dependence of the motion of the sap upon *common physical agencies.* In the same tree, this sagacious person observed, that in a cold cloudy morning, when no sap ascended, a sudden change was produced by a gleam of sunshine of half an hour, and a vigorous motion of the fluid. The alteration of the wind from the south to the north, immediately checked the effect. On the coming on of a cold afternoon after a hot day, the sap that had been rising began to fall. A warm shower and a sleet storm produced opposite effects." [Well: is there any physiologist who denies the effect of heat and cold, upon physiological action? Are not the manifestations of life in the winter-torpidity of cold-blooded animals dependent on these changes?]

"Many of his observations likewise show, that the different powers which act on the adult tree, produce different effects at different seasons. Thus in the early spring, before the buds expand, the variations of temperature, and changes of the state of the atmosphere, with regard to moisture and dryness, exert their great effects upon the expansion and contraction of the vessels; and then the tree is in what the gardeners call, its bleeding season." [And is not the physiological effect of atmospheric dryness and moisture equally apparent in the human frame; in phtisis, in asthma, in rheumatism, in gout?] "When the leaves are fully expanded: the great determination of the sap is to these new organs. Hence, a tree which emits sap copiously from a wound, while the buds are opening, will no longer emit it in summer when leaves are perfect; but in the variable weather towards the end of autumn, when the leaves are falling, it will again possess the power of bleeding in a very slight degree in the warmest days, but at no other time." [Who ever doubted that heat and cold acted respectively as a stimulus and a sedative on the animal fibre?]

"In all these circumstances, there is nothing analogous to the irritable action of animal systems. In animal systems, the heart and arteries are in constant pulsation. Their functions are unceasingly performed in all climates and in all seasons; in winter as well as in spring, upon the arctic snows and under the tropical suns. They neither cease in the periodical returns of their nocturnal sleep, common to most animals, nor in the long sleep of winter peculiar to a few species. The power is connected with animation, is limited to beings possessing the means of voluntary locomotion; it co-exists with the first appearance of vitality, it disappears only with the last spark of life." [Can Sir H. Davy tell us how the partial suspension of vitality during winter in vegetables, differs from the same phenomenon in cold-blooded animals? Have not both the one and the other a vital power of resisting to a great degree, the effects of cold, and of preserving the vegetable and animal temperature unaffected by the atmospheric change? Can Sir H. Davy make the alligator it here, that a man may be an excellent chemist, and a miserable physiologist; and that his notion of the life of animals being a sub-agent of some governing superior principle, will carry him just as far beyond the bounds of common sense, as of orthodoxy. This is reviving the Archæus of Van Helmont, and the Anima of Stahl. That the superior immaterial principle which is usually ascribed to man, as a characteristic of his species, is common to the whole tribe of animals from the human being to the musquito, the oyster or the earth-worm, is an opinion not warranted by known facts or sound philosophy.

The best account we can give of a vegetable and animal, is nearly that of Mr. Keith, in his *System of Physiological Botany*, (Vol. II, p. 471. London, 1816.)

A vegetable is an organized and living substance, springing from a seed or a germ which it reproduces: effecting the development of its parts by the introsusception and assimilation of *unorganized* matter, derived from the soil by means of the roots, or from the atmosphere by the action of the leaves; and possessing fibres irritable and contractile on the application of stimulus; but possessing no nervous apparatus, serving as the organ of feeling or of voluntary locomotion.

An animal is an organized and living substance, springing from an egg, or embryo, which it again produces; effecting the development of its parts by means of the introsusception of *organized* substances or their products: possessing fibres irritable and contractile on the application of stimulus; and a nervous apparatus, the organ of perception or feeling, of intellect, of moral qualities, and of voluntary motion.

Animal matter can generally be distinguished from vegetable matter, by the strong phosphoric odor which the former does, and the latter does not exhale while burning.

and the sea-horse, or the white bear, companions of the same climate.]

"Vegetables may be truly said to be living systems in this sense, that they possess the means of converting the elements of common matter into organized structures, both by assimilation and reproduction." [In the name of common sense what are these but the peculiar and characteristic powers of life? Of life, acting independently in these respects of any law of mechanical or chemical philosophy? Is the production of progeny one of the common *physical agencies?*] "But we must not suffer ourselves to be deluded by the very extensive application of the word *life*, to conceive in the life of plants, any power similar to that producing the life of animals. In calling forth the vegetable functions, *physical agents* alone seem to operate; but in the animal system, these agents are made subservient to a superior principle. To give the argument in plainer language, there are few philosophers who would incline to assert the existence of any thing immaterial in the vegetable economy"—[no more than in the animal economy of a elephant, or a sponge.] "Such a doctrine is worthy only of a poetic form. The imagination may easily give dryads to our trees, and sylphs to our flowers, but neither dryads nor sylphs can be admitted in vegetable physiology; and for reasons nearly as strong, *irritability and animation ought to be excluded.*" [Upon this strange assertion, it will not be unfair to observe, that Sir H. Davy ought to have furnished more unexceptionable reasons, in support of an opinion, contradicted by every known botanist and physiologist, during a century past, and universally rejected in the present day.]

It is probable that the decompositions and combinations which take place during digestion, assimilation and secretion, both in animals and vegetables, are results of galvanic action, put in force by the principle of life; but no other power or principle than that of life, can account for reproduction, as the result of the stimulus given to the ovum, the seed or the germ, by the male of every species, both in vegetables and animals. No chemistry of the laboratory, no "physical agency" can explain this.

The introsusception, digestion, assimilation and secretion of food, both in animals and in vegetables, are processes carried on in direct defiance of all mechanical and chemical laws of action, (Sir H. Davy's Physical Agencies,) chemical action takes place and prevails in dead only, not in living matter. The living powers of vegetables and animals counteract and control chemical action.

That irritability, contractility, and increased action, can be produced in the vegetable as well as the animal fibre, by the application of any stimulating substance, is well known to botanists; particularly in the more manifest instances of the mimosa, the dionœa muscipula, the drosera, the cactus tuna, the berberis, the stylidium glandulosum, &c. So, the action of light upon the motion of a plant; the action of heat on the development and maturation of leaves, flowers and fruits; the attraction of distant nutriment and moisture on roots, and above all, the phenomena of impregnation and assimilation, seem to have no more to do with Sir Humphrey Davy's Physical Agencies than they have with the phenomena of a game of chess, or the music of a ball-room. Can any "physical agency" account for the apparent voluntarity that so frequently takes place in the impregnation of the water-lily? Or for the sleep of plants, or the incessant motion of the leaves of hedysarum gyrans? Respect for the well-earned reputation of Sir H. Davy, as a chemist second to no other, has induced us to dwell upon this refutation, perhaps needlessly. We shall, therefore, proceed, and in the course of our reasoning, consider a plant as other botanists and physiologists consider it, a living being.

Manures then may act by *stimulating the fibres of a plant to stronger action.* By inducing them to eat and drink more, and digest and assimilate more perfectly: as when we take pepper and mustard, and salt and wine in reasonable quantity, or quinine, when vital action is languid. Also, by exciting the healthy living fibre to throw off a diseased or dead fibre; as we apply stimulant applications to ill-conditioned sores to excite the healthy parts to slough off the diseased parts.

The substances used that produce this effect, are generally lime, gypsum, salt and soap-boiler's ashes. Hitherto, they have been employed empirically; the point of view in which they are now considered, was hinted at by Kirwan, in a solitary sentence already quoted, and stated at length in Cooper's edition of the *Domestic Encyclopædia;* but no where else that we recollect.

If these substances do not act as forming part of the pabulum or food of the plant; if they do not act by altering the mechanical texture of the soil, there is no other mode of accounting for their action than that now suggested; unless, indeed, we recur to Kirwan's theory of their *septic* power, which is by no means established by experience in practice, or by sufficient experiments instituted for the purpose. Nor if it were, will it account for the effects produced. We are not prepared or disposed to deny, that these substances, employed in useful proportions, *may* act as septics upon undecomposed manure in the ground; but nothing certain of this nature is yet known on sufficient authority.

They do not constitute the food of plants. Nothing can enter into the composition of a plant, unless accidentally, that is not an essentially component part of a vegetable. We find silicious, aluminous, calcareous earths in plants; we find common salt, gypsum, soda, potash, phosphate of lime and other substances in plants, when these substances are found in the soil wherein the plants grow. But the same plants can and do grow to perfection without them. When these substances are dissolved in minute quantities in the juices which the plants by their roots drink up from the soil, they will of course enter into the sap; and if the vital power of the secretory vessels be not strong enough to excrete them, they will be deposited in the vessels and joints of the plants. As the silicious tabasheer in the joints of the bamboo; as the silicious earth in the straw of the cerealia, and the scowring flag. So, the charcoal of an old tree will very often strike fire with steel; not so the charcoal of a young tree. So, gypsum has been found in rhubarb, and calcareous earth in potatoes manured with lime. So, the salsola sodæ will yield soda near the seaside, and potash, when planted for some time inland. All these instances are manifestly cases of accidental product and the substances enumerated are by no means essential parts of the plants wherein they happen to be found.

I conclude, therefore, that they cannot be considered as pabula. Moreover, the increase in weight of vegetable food from these manures cannot be accounted for from the weight of the manure put on. Thus we were present at the laying out of a clover-field, of which one half was sown with clover without manure of any kind, and the other half was sown with ground gypsum after the clover had just appeared above ground, in the proportion of not quite two bushels, but more than a bushel and a half to the acre. The clover hay from the unmanured part, was a ton and a half per acre; and double that quantity from the portion of the field manured with gypsum. Now, the quantity of gypsum employed, even if every particle of it had been taken up and converted into food, could not have added more than its own weight, or about 120 lbs.; but its effect was, to produce an increase of a ton and a half. So, when lime is strewed on the soil, it remains there; it is not eaten and digested by the plant. Both lime and gypsum also, are manures for more than one or two years. Hence, the increase of vegetation cannot be accounted for from their mechanical action, or from any chemical action, or from their forming any part of the food of plants. As to chemical action, it is none; for gypsum is not decomposable in the common atmospheric temperature; and the lime in a week becomes carbonated by attracting carbonic acid from the atmosphere.

As to common salt, we know too little, experimentally, about it. Mr. Legrand (*Young's Annals of Agriculture*, Vol. V. p. 149) found that so far as sixteen bushels per acre, it was a useful manure; from thence to forty bushels, it gradually destroyed vegetation. Mr. Parke, the chemist, published a letter on the advantages of using salt as a manure, which Judge Peters procured to be republished in Philadelphia, but we know no result of experience on this subject.

Soap-boiler's ashes are a common manure in England; they consist of Glauber's salt, common salt, sulphuret of soda, and various impurities, whose action can only be explained on the suggestions we have just made.

Sea-sand, the mud of salt marshes, and other substances of a saline nature, must be referred to the same explanation. They are all stimuli—they irritate the fibres of the roots—they excite stronger action. The perspiration from the leaves in a clover-field manured with gypsum, is obviously increased, as well as the general vigor and growth of the plant.

Manures may act by *furnishing nutriment to the plant:* as a pabulum or food, convertible into the substance of the plant itself. Nothing can be an essential part of a plant that does not, when decomposed, furnish the substance of which a plant consists. Of what substances does a plant consist? Take a piece of oak-wood, fresh from the tree; weigh it; cut it into small pieces; put it into a glass retort; lute on a glass receiver; and to this, lute on also a bent glass-tube to go under the shelf of a pneumatic trough, and convey into inverted receivers the gases that would otherwise escape; apply fire gradually; distil and receive all the products. First, an aqueous and acid vapor will come over, which may be condensed in the receiver. This is accompanied with an empyreumatic oil, and is, in fact, the pyroligneous acid procured by the gunpowder-makers, when they distil wood to make their charcoal. Then come over gases, viz.: carbonic acid gas, carburetted hydrogen, carbonic oxide and hydrogen. In the the retort, when more products come over, you get charcoal, the same bulk as the wood, and about one-fourth or one-fifth part in weight.* Burn the charcoal, and about one part in 250, by weight, in an old tree, will be ashes; the rest will burn away in the open air, in the form of carbonic acid gas. Of these ashes, part are carbonate of potash, and the rest, earths of the same nature with the soil in which the tree grew. The carbonate of potash in the ashes of oak-wood, amounts to about four pounds in a bushel, or 1-15 part. In hickory they amount to six pounds in a bushel of ashes.

The essential oil of the pyroligneous acid, is convertible by means of a red heat in an iron retort, into carbonic acid and carburetted hydrogen; that is, into carbon and hydrogen.

The acid liquor, which is vinegar, is formed out of oxygen, carbon and hydrogen.

The water is oxygen and hydrogen.

The gases that come over, are chiefly carbon and hydrogen; in the carbonic oxide, a small quantity of oxygen.

The earths are not essential to the plant, either in kind or quantity; and the alkali is about $\frac{1}{15}$ of

* By the experiments of Mr. Mushet, of the Clyde iron works, 100 parts by weight of oak-wood, furnish 76,895 of gas, water and acid; 22,682 of charcoal; and 0,432 of ashes, of which last, we know about 1-15th is carbonate of potash.

$\frac{1}{250}$th, and of this nearly one-half is carbonic acid, which is oxygen and carbon.

Hence, a plant may be considered as composed of carbon and hydrogen, with oxygen in a far less proportion than either.

Suppose we take pine-wood instead of oak: the only difference will be, that from the resin of the pine we shall obtain more carburetted hydrogen by means of a red heat, but the elements of the plant will be the same; and so will it be whatever plant we take for the experiment. In this analysis nothing is lost. The whole plant, decomposed into its elements, is there. Hence, if a plant contain nothing as a uniform and constant part of it, but carbon, hydrogen and oxygen, and about $\frac{1}{7000}$th part of potash, nothing can afford nourishment to a plant; but what is decomposable into carbon, hydrogen, and oxygen, either spontaneously when exposed to the atmosphere, or by the action of the vegetable organs of the plant itself.

It is true, in some plants already mentioned, and which contain gluten and albumen, nitrogen becomes a constituent part; this can be furnished either by the atmosphere, or by animal manure.

We make use of chemical reasoning and chemical terms, and we call in the aid of physiology, because we are not addressing ourselves to the servant who ploughs the ground, but to his master. It is in vain to suppose that the theory of husbandry can be understood by a man who is not well acquainted with the elements of chemistry and physiology. This last most useful branch of knowledge, is strangely neglected in our colleges and universities; although it lays at the root of all physics, of all metaphysics, and of every disquisition relating to the nature of animals and vegetables. The wagon loads of words without meaning, that an accurate knowledge of the elements of physiology would enable us to dispense with, is truly astonishing. But, *à nos moutons*.

Under what forms, when applied, are carbon, hydrogen and oxygen taken into a plant as nutriment?

What parts of the plant does nature employ for the purpose?

Hazenfratz and Kirwan were both persuaded that carbon was the chief pabulum of plants. It is true, that we procure from 20 to 25 per cent. of charcoal, and that the carbon in the condensed liquor, and in the gases obtained, is considerable: but, we should probably mistake, in ascribing more than one-half of the weight of a plant to carbon; the hydrogen and the water (hydrogen and oxygen) will, probably, make up the other half.

Carbon alone, whether applied in the shape of charcoal, coal, or soot, is utterly indecomposable. Sir H. Davy says he dissolved a small part of charcoal in water in a tube hermetically sealed: but the only experiment really worth noticing, is one by Arthur Young, who dissolved charcoal by boiling it in a solution of carbonate of potash; in which form, it was a most powerful manure. I know of no way in which it can become part of the food of plants, but when taken up by the roots in its nascent state of extrication, by decomposition of the substances, fluids, or gases containing it, or by the decomposition of atmospherical carbonic acid by the leaves; which, indeed, is the great source of its supply.

Hydrogen is found in connexion with water, and almost every other decomposable substance acting as a manure, whether producing fluids or gases.

Nor is there any difficulty in accounting for oxygen contained in plants, so abundant on every side are the sources of it.

But let us examine the most usual manures of nutriment.

Stable-yard manure.—As this has been a vegetable before, there can be no difficulty in conceiving that it may become a vegetable again. It has either fermented into the soluble butyraceous mass of the old farm-yard management, or it is employed fresh, and permitted to undergo a gradual decomposition in the soil. In the first method, it acts sooner, and in the same quantity more efficaciously: but this management of a dung-heap, occasions a loss of at least one-half of the nutritious matter, dissipated in the various gases that are extricated, or permitted to run away by the rains falling on the dung-heap. Every such heap of dung should have a covering over it, to preserve it from excessive heat and from moisture.

The great advantage of a long previous fermentation of the dung, especially when mixed with fresh lime, *is to kill the seeds of weeds*, which the mere digestive powers of horses and cattle are unable to effect. In every other respect, the most advantageous and economical use of dung, is to plough it under ground in its fresh and recent state.

Night-soil:—Beyond all doubt the most powerful and efficacious of all manures. It would be no exaggeration to say, that if the economy used by the Chinese, or even by the French and other inhabitants of the continent of Europe, were used in America, at least ten millions worth of produce might be added to the crops of this country. In France, the *fosses d'áisance inodores*, and the dried night-soil sold as a poudrette for manure, are in common use. This substance should be mixed with at least an equal quantity of slacked lime, which takes away all odor, and then, with three or four times its quantity of common earth, and made into a compost.

Mud from ponds—the cleanings of ditches, &c.; Require to be previously fermented to kill the seeds of weeds.

The sweepings of streets are liable to the same remark.

Ground bones.—These contain phosphate of lime, carbonate of lime, and from one-third to one-half of animal gelly fat, and albumen. In Paris, bones are employed in the manufacture of portable soup. The bones are boiled in water to get at the fat and mucilage; and they are digested in diluted muriatic acid for about ten or twelve days; then washed in cold water to separate the solution of lime and phosphate of lime: the transparent gelatine remains in shape of the bone. It is dissolved in boiling water; it is flavored to the palate of the cook who manufactures it; concentrated into portable soup, and so sold.

When young, we attended a veterinary school in London, and a repository of dead horses, at St. John's, Clerkenwell. Let us give the history of a DEAD HORSE. The owner sends him to the currier, to whom he is worth about half a guinea. The currier sends him to the repository, where he is skinned, and dissected before the pupils who attend, and who pay from a guinea to two guineas a year for the privilege. The currier takes the skin. The flesh is cut off, boiled, and sold to the retailers of cats' meat and dogs' meat, who sell it about the streets of London at three half-pence per pound. The bones being broken and boiled, the fat, when cold, is taken off and sold to the makers of cart-grease for carriages. The bones are then ground by means of a steam-engine, and sold in powder to the farmers, to be used (like soot) as a top dressing for wheat: both these manures containing volatile alkali when decomposed, and supplying nitrogen. The bones contain, after being boiled, full one-third of their weight of animal gelatine, which, undergoing putrefaction and gradual decomposition, becomes a valuable manure. All the bones from the plains of Waterloo, were actually collected and exported to England, principally to Hull. The price of ground bones at that port, about three years ago, was 2s. 10½*d.* sterling per bushel.

The bodies at Waterloo, were first searched over for money, watches, trinkets and clothes. Then came the purveyors of human hair, for the supply of the makers of false hair, wigs, curls and frizettes; then came another class, who extracted from the dead bodies, all the sound teeth, for the supply of the dentists; then, when the flesh had putrefied, the collectors of bones searched the field for *their* harvest.

Frequently, the ground bones, instead of being bought by the farmers for manure, are sold to the manufacturers of volatile alkali and sal ammoniac, for distillation; sometimes, for the hafts of knives and forks, and the common imitations of ivory.

Woollen rags, refuse parings of skins, and other animal matters, having previously been vegetables, are well adapted, by gradual decomposition, to be converted into vegetables again.

Spring crops of tares, vetches, buckwheat, or any other vegetable sown early, and ploughed in, just as they begin to flower, constitute a very judicious mode of supplying manure to the earth, when no other is to be procured. It may be asked, if you plough into the ground the crop which the ground has already nourished, what do you gain? The reply is, you gain the whole of the nutriment that the crop has acquired from the air, and from the decomposition of water: an amount of nutriment, probably, equal to one-fourth, *at least*, of what the plant can furnish by gradual decomposition. This brings us to the question, what parts of the plant does nature set to work to obtain nutriment and supply the growth?

First—The *roots*. There is no evidence whatever, that the roots of a plant can take in any solid matter, or any gaseous matter, unless previously dissolved in water. The sap of every tree and plant, whether ascending or descending, is a fluid: holding in solution more or less of the substances destined to become parts of the plant itself. How does this fluid ascend by means of the roots? Assuredly not by capillary attraction, which would stop at an inch or two; nor by any of Sir H. Davy's "physical agencies," which are utterly worthless to account for the phenomenon. Our mode of explaining it, is as follows: a drop of fluid, containing nutriment, comes in contact with a root fibre in search of nutriment. The mouth of the fibre, that is, the internal sides of the tube, become stimulated; they contract on the drop of fluid. and by a contraction *à tergo*, propel it upwards, where another part of the containing tube being stimulated in like manner, contracts in like manner, and the drop is thus propelled to the very top of its course, in consequence of the irritability of the living fibres of the containing vessels.* In its course, it undergoes the processes necessary to form it into the nutriment, and assimilate it to the substance of the plant. This is done by means of the peculiar organization of each plant, acting as the nature of the plant requires.

Were we to propose a theory, it should be, that the organization of vegetables and animals, includes and arranges a series of galvanic batteries; by means whereof, decompositions and recompositions are effected in organized bodies, which the chemistry of the laboratory cannot explain. We strongly suspect, that when two dissimilar bodies come in contact, electrical effects, chemical effects, and caloric, more or less, are always produced: whenever two dissimilar bodies, with an intervening conducting fluid, capable of acting upon one of them, come together, galvanic effects are produced. And these arrangements are certainly found in every living vegetable and animal. But the view we can as yet take, is not clear: we see as yet through a glass darkly; and, to use the language of the poet, "the present affords but a glimpse through the gloom." However, discoveries are in progress, and in this, as in every other respect, we may cheeringly say of the march of mind, *Ca Ira.*

During the decompositions of the sap, the observations of Gay-Lussac and Thenard, which we see nothing to controvert, will apply. Whenever hydrogen and oxygen unite in a vegetable, so that the oxygen is to the hydrogen in a greater proportion than is found in water, the result is an acid. Whenever they unite in the same proportions that form water, the produce is saccharine, or mucilaginous, or fecula, or woody fibre. Whenever they unite so that the oxygen is in a less proportion than in water, we have resins, oils, gum-resins, caoutchouc, &c. In these cases, carbon forms the third ingredient.

In pine and fir trees, there seems no doubt but water itself is decomposed, and oxygen is given out, during the formation of pitch, turpentine, &c. Is the common prejudice, so prevalent in South Carolina, in favor of a summer's residence in the pine-woods, confirmed by this explanation? It seems so to us.

So much for the function of the *roots*. But the

* We are aware of the theory of Monsieur Dutrochet in his late book, "*L'Agent immediate du mouvement vital dévoilé dans sa nature, et dans sa mode d'action, chez les végétaux et chez les animaux.*"—8vo. Paris; 1826. M. Dutrochet is of opinion that the lymphatic tubes through which the sap ascends, are incontractile; but for no valid reason in support of this doubt that we can discover. If the vegetable fibre be possessed of vegetable life, it must be contractile; this being the characteristic property of living fibre. Nor can his obscure explanation by endosmose and exosmose be satisfactorily admitted, without admitting the contractile property of the cells and membranes introduced in his explanation, nor does the application of galvanism in the experiment of M. Porret, or in that of M. Dutrochet, negative the contractility of the living fibre—especially as those experiments did not succeed with inorganic substances.

leaves also play their part in the business of nutriment. The experiments of Priestley, Ingenhouz, Sennebier, and Woodhouse of Philadelphia, have established the fact, beyond all doubt, that the carbonic acid of the atmosphere, is decomposed by the leaves of a plant, when the leaves are stimulated into action by the light of the sun. This, we suspect, is one of the great sources of the supply of carbon; and of course, a crop ploughed in, adds to the soil as so much gain, all that the leaves have acquired from the atmosphere. But this addition of carbon, induces also from the roots, a greater supply of hydrogen and of oxygen; which would not have been needed, had not this additional carbon been procured by the industry of the leaves. The theory of manure, therefore, by means of crops ploughed in, while in early flower, is supported by all the considerations above suggested.

From the Rev. O. Dewey's "Old and New World."

ENGLISH AND AMERICAN ECONOMY.

I observed that a considerable number of passengers (on board a steamboat) carried a comfortable pic-nic box or basket with them, and spread their own table. With some, doubtless, this provision proceeded from a fastidious taste that feared some poisonous dirt would be found in the common fare of a steamboat. But with many, I presume, it arose from a habit which presents a marked difference between the people of Eng'and and of America—I mean the habit of economy. In America we are ashamed of economy. It is this feeling which would forbid among us such a practice as that referred to, and not only this, but a great many more and better practices. In England economy stands out prominently; it presides over the arrangements of a family; it is openly professed, and fears no reproach. A man is not ashamed to say of a certain indulgence, that he cannot afford it. A gentleman says to you, "I drive a pony-chaise this year; I have put down my horse and gig, because I cannot pay the tax." A man whose income and expenses and style of living far exceed almost any thing to be found amongst us, still says of something quite beyond him, which his wealthier neighbor does, "We are not rich enough for that." One of the most distinguished men in Europe said to me, when speaking of wines at his table, "The wine I should prefer is claret, but I cannot afford it; and so I drink my own gooseberry." I have heard that many families carry the principle so far, that they determine exactly how many dinners they can give in a year, and to how many guests; nay more, and how many dishes they can put upon the table when they do entertain.

This frankness on the subject of economy is amongst us a thing almost unheard of. Not that we are more wealthy, but, as I conceive, less wise. The competition of domestic life among us is too keen to admit of any such confessions of internal weakness. We practice economy by stealth. Nor is that the worst of it; for one consequence of this habit of feeling is, that we practise too little. When a stranger looks upon the strife of business in our villages and cities, he imagines that he sees a very covetous people; but a nearer observation would show him that much of this eager and absorbing, and almost slavish, occupation, is necessary to sustain the heavy drains of domestic expenditure. It is extravagance at home that chains many a man to the counter and counting-room. And this extravagance is of his own choosing; because he knows no other way of distinguishing himself but by the style of living. Would he but conceive that he might better elevate himself in society by having a well-read library, by improving his mind and conversation, by cultivating some graceful but comparatively cheap accomplishment, he might live a wiser and die a richer man. Who could hesitate to choose between such a family, and one whose house was filled with gorgeous furniture; where the wife and daughters are dressed in the gayest of the fashion, and the husband and father banishes himself the live-long day, and half the night, from that pleasant mansion, to toil and drudge in the dusty warehouse? He sleeps in a very grand house; he lives in a counting-room!

From the Penny Magazine.

WOLF-CATCHING IN NORWAY.

In Norway, and perhaps in some other northern countries, the following very simple contrivance is used for the capture of the wolf:—In a circle of about six or eight feet in diameter, stakes are driven so close to each other that a wolf cannot creep through, and which are high enough to prevent his leaping over them. In the midst of this circle a single stake is driven, to which a lamb or a young kid is bound. Around this circle a second is formed, of which the stakes are as close and as high as the inner one, and at a distance not greater than will permit of a wolf to pass conveniently, but not to allow of his turning round. In the outer circle a door is formed, which opens inward, and rests against the inner circle, but moves easily on its hinges, and fastens itself on shutting. Through this door the wolves enter, sometimes in such a number as to fill the enclosure. The first wolf now paces the circle in order to discover some opening through which he can get at the lamb. When he comes to the back of the door which is in his way, he pushes it with his muzzle, it closes and fastens, he passes by, and goes the round for the second time, without being able either to enter the inner circle, or to retreat from the outer. At length he perceives that he is a prisoner, and his hideous howling announces to those who have constructed the trap that he is taken, who immediately come and despatch him. It is said that this sort of trap is also used for foxes, and even occasionally for mice.

From the Maine Farmer.

MAKING BUTTER.

In a few remarks on this subject, it is not necessary for us to tell the dairy-woman that it is of the first importance that her milk-pails, pans, pots, churn, &c., should be kept perfectly clean and sweet, for they are as fully aware as we can be, that unless this first grand essential of dairy management is *strictly* attended to, their whole efforts to produce either good butter or cheese, are in vain. But after all their care and precaution, their expectations are sometimes disappointed—the produce of this labor does not, in quality, come up to what they anticipate, and for what earthly reason they are not able to tell. It appears to them, that no neglect on their part can be the cause—they have been careful that all the preliminaries and the whole operation should be performed with skill, but still they are disappointed—there is wrong management somewhere, but it is beyond their ken to discover it. There are some few facts on this subject, which we have learned from agricultural books and papers, and confirmed by experience, which perhaps are not so generally known as they should be.

That there is a great difference in the milk of different cows, every one of limited experience must have noticed, and that there is an equal difference in cream, and consequently in the butter made from it, is a fact equally apparent to an observer.

If a cow is driven a long distance or driven fast shortly before milking, it injures the quality of the milk, and it will not produce so much or so good cream.

If milk is disturbed after it cools and before the cream rises, it injures its quality and diminishes the quantity. Care should, therefore, be taken to strain the milk as soon as possible after it is drawn from the cow and before it cools. If milk be kept warm for any great length of time after it is strained, the cream will not rise to any degree of perfection. Therefore, the quicker the milk cools after it is in the pans, the greater quantity and better quality of cream will you obtain. Wholesome pure air is also an essential to raising cream in any degree of perfection.

Cream is lighter than milk, and the better the quality of the cream the lighter it is. Consequently, the cream that first rises to the surface, is the best. None but the richest and lightest particles of cream can rise through thick milk; therefore, such milk gives cream of a superior quality, but less in quantity than thin milk. But the milk is better as it retains a portion of the cream in it. The milk in the cow's udder is, in some degree, similar to what it is after standing some time in the pail. The richest rises to the top, hence, the first drawn is not so good, and will not produce so much or so good cream as the last, and should be set in separate pans.

In order to produce a superior quality of butter, the best cream should be obtained, and in no case suffered to stand until it is mouldy, or even until it is quite sour before it is churned. It should never be diluted with water, or made any warmer than the milk was when taken from the cow. When the process of churning is commenced, it should be steadily continued until butter is produced, which should be immediately taken from the churn and all the milk washed out that can be conveniently. If it is sufficiently hard, it is better to free it from milk entirely; but this is not always the case. It should, therefore, be set in a cool place, and worked thoroughly with the butter ladle the next day. Having entirely freed it from milk, prepare a mixture of ground alum salt, saltpetre, and refined loaf sugar, in proportions of three parts of salt to one of sugar, and work in thoroughly one and a half ounces to every pound of butter, and pack it into jars and firkins covered tight; and at the end of twelve months you will find it sweet.

From the Genesee Farmer.

THE TOAD.

There are few animals so universally disagreeable, or which are so generally considered an incarnation of every thing vile, as the toad, *bufo vulgaris* of the naturalist. Milton understood the amount of the prejudice against the toad, when he placed the arch fiend in the disguise of this reptile close to the ear of sleeping Eve, in Paradise; for we may be sure Lucifer would not have been guilty of the indiscretion of approaching her in in that form when she was waking. But though the toad seems to have been marked out for the hate and aversion of mankind, there are few reptiles whose habits are more worthy of notice, none that are more harmless, and few that render more actual service to man. It is true, neither the frog or the toad, particularly the latter, would be an agreeable inmate of the "kneeding trough," or a pleasant companion in the "bed chamber," but in the field or in the garden, they devour multitudes of insects that prey on the labors of man, while they meddle with none of the plants or fruits that require his protection or cultivation.

With the approach of cold the toad retires into the earth, and in a torpid state awaits the return of the spring. If surprised in this state by any change in the face of the earth, that could have the effect of placing him beyond the influence of the seasons, the toad, it is supposed, can remain uninjured in this state for an indefinite length of time; and in this way the discovery of frogs and toads, in deep excavations, and even in solid blocks of stone, has been attempted to be accounted for. The celebrated geologist Buckland, however, seems to doubt whether the evidence in proof of such discoveries, is such as to warrant implicit confidence in the details. We should imagine that if correctly represented, the discovery of the one at Lockport, while excavating the limestone of the mountain ridge, was as little liable to deception or doubt, as such matters usually can be; and we know of no philosophical reason, why, if a toad can lie torpid for one year, as has been proved by burying them in pots, they might not as well exist one hundred, or a thousand, if the proper temperature for ensuring torpidity was preserved.

Some writers have denied that the toad, under any circumstances, was poisonous; but this is a mistake. When in danger, or when irritated, the tubercular elevations on the backs and sides, have the power of secreting a milky fluid, as every one may readily ascertain, and every school-boy who is in the habit of pelting them with stones well knows. This fluid, given for defence, as we suppose, is decidedly poisonous, as its effects on cats, and other animals, fully prove. This is the only power of injuring it possesses; and this secretory and offensive power appears to reside in the skin, as the animal is frequently skinned and sold with the frog in the markets of European cities, for food, and eaten with impunity.

Toads after the time of breeding is over, forsake the pools of water where they assemble in the spring, and in or near which, they usually pass the winter, and scatter themselves over the land, and when once they have chosen a favorable position, if not disturbed, they rarely quit it for the seasons, and some have been known to retain possession for several years. From these retreats they emerge towards nightfall, or in the evening, and feast on snails, flies, bugs, or any living insect that falls in their way. In a garden their services are thus invaluable; and some gardeners introduce and protect them through the summer, for the aid they render in the destruction of worms, &c.

Notwithstanding his clumsy and ungainly appearance, there are few animals so quick of motion as the toad, and this is shown most distinctly in taking his insect food. It will not unfrequently, in a warm summer evening when doors are open, make its entrance into the house, where it feeds on flies that approach. Seated on its haunches, it surveys the floor with great gravity, but if an unwary fly alights within four or five inches it disappears with incredible quickness. There can be a slight motion of the toad discovered, a quick snap as of the jaws is heard, but the position of the animal is unchanged, while his prey vanishes with the velocity of light. A close examination shows, however, that there is a slight motion of the body forward, without moving the feet; and the snap is produced by the shutting of the mouth after the tongue has seized and secured the insect, though so quick is the operation performed, that the tongue is never distinctly seen. We have often seen this feat performed by placing a fly or bug, on the end of a grass stalk, and pushing it gradually towards the toad when he first makes his appearance at dusk. The lightning's flash is hardly more quick or fatal than the snap of this reptile to the insect he aims at.

To enable the toad, frog, chameleon, and some other reptiles to seize their prey, the tongue has a curious conformation; "it is of great length, its root is attached close to the *fore part* of the lower jaw, while its point, which is cloven, is turned backwards, extending into the throat, and acting like a valve in closing the air passage into the lungs. If, when this animal has approached within a certain distance of the insect it is about to seize, we watch it with attention, we are surprised to observe the insect suddenly disappear, without our being able to determine what has become of it. This arises from the frog (or toad) having darted out its tongue upon its victim with such extreme quickness, and withdrawing it with the insect adhering to it, so rapidly, that it is scarcely possible for the eye to follow its motion." (Roget's Physiology.)

A fact which was related to us a few days since by a gentleman, will furnish a curious illustration of the habits of this animal. He was mowing in a field, when he disturbed a nest of the common humblebee. As they were quite numerous, and appeared very pugnacious withal, he concluded to let them alone until they became more quiet, when he determined to visit the nest again, and appropriate their stores to himself. In the course of a few hours he repaired to the spot, when to his surprise he saw a large toad had planted himself directly before the place of egress for the bees; and he seemed so satisfied with his position that the gentleman determine dto ascertain if possible his business in that place. He soon saw that every bee that showed himself disappeared in some mysterious manner, and that a slight snap, invariably connected with their disappearance, convinced him it was in some way owing to the toad, and that in this way the animal was doing him good service. It was but a short time before every working bee was despatched, not one escaping: and then, by slightly disturbing the nest, the queen bee or drones that generally are found to the number of three or four among humblebees, were induced to venture out, and instantly share the fate of their companions. The honey fell to the share of my informant; the toad appearing perfectly satisfied with his allotment of the "spoils."

From the Rural Library.

TAME RABBITS.

Their profit—fecundity—food—and management—also, directions for building their huts.

1. These little animals are really very profitable; their food costs nothing, and their produce is extraordinary; they will breed eleven times in a year, bringing forth six or eight young; thus at the end of four years a pair of rabbits would produce nearly a *million and a half.*

2. In its wild state it finds warmth and safety by making a hole in the ground, often to a great depth, these holes or burrows branch off, forming chambers where the animal can obtain such a temperature as suits its habits and its young ones.

3. Rabbits of the domestic breed, like all other animals that are under the protection of man, are of various colors, white, brown, black, mouse color, yellow, and speckled of all colors; its native color is brown, but the white with red eyes, and the large black and white spotted, and the yellow, are the most valuable. Tame rabbits are much larger than wild ones, and their flesh very delicate and nutritive—very little inferior to chicken, particularly that of the yellow colored.

4. Rabbits are kept in all parts, and to considerable extent in some places, particularly in England, where there are two very extensive establishments, one in Berks, the other in Oxfordshire; the former feeds white rabbits on account of the superior value of their skins, which are used for hats and trimmings; the latter feeds about nine hundred in huts, or hutches, placed in a building erected and kept solely for that purpose; they make about 36 bushels of dung per week, which generally sells high, being very powerful, two loads is sufficient for an acre of land.

5. The rabbit-house should stand on a dry foundation, on a gentle slope; be well supplied with air, and also with drains and water courses, by which means all rain and moisture is rapidly carried off. Exposure to much damp, whether in or out of doors, is fatal to rabbits; they are like sheep liable to the rot.

6. In large establishments the huts are generally placed in rows one above another, gently inclining backwards, with holes in the hind part to throw off the urine; the lower ones resting upon stands about 18 inches from the ground, for the convenience of cleaning under them. Hutches for breeding rabbits must have two rooms—a feeding and a bed room, with a sliding door to confine them while cleaning. Single room huts

are sufficient for weaned rabbits or bucks, as the latter must always be kept separate; but such for the convenience of cleaning should have a false bottom, like a bird-cage.

7. The floors of hutches should be of hard wood, planed very smooth, that their water may run off, as it is considerable when they are fed on green food; and their troughs should be edged with tin or iron, as their teeth are very destructive to any substance not hard enough to resist them. The troughs should also be narrower at the top than bottom, to prevent them scratching out their food, or dunging in it. Rabbits should be fed twice or thrice a-day. A small hoe and a rough-haired brush, are the best implements for cleaning their houses. When their dung is intended for sale, no litter should be allowed; but when it is to be used on the farm or garden at home, the huts should be supplied with perfectly dry refuse, hay or straw, (not clover,) every day. Their dung, when gathered up, should be kept in a bin out of the rabbit house, as impure air is particularly to be avoided; for where confined in any number, they will not remain healthy without plenty of fresh air. A run abroad for young rabbits is beneficial; but all rabbits must be separated as soon as they are fit for breeding, else they will tear each other to pieces. They are quarrelsome and mischievous animals, and the bucks, when at liberty, destroy many of the young.

8. With respect to form and shape, the short-legged rabbits, with breadth and much flesh are the most hardy and fatten quickest; but these can only be obtained by time and careful selection. There is a large variety called the "*lop-ears*" having much bone, length and depth of body, large ears and eyes, and their flesh is high-colored, firm and more savory than the other varieties; and when cooked like the hare, which at seven months old they nearly equal in size, they make a good dish. The large white, and yellow and white species, have more delicate flesh, and cooked in the same way, much resemble the turkey in flavor. The most fancy sort are the lop-eared "smuts;" they have two, three, or four spots of color on each side the nose, and in proportion to the number and regularity of these spots, there and on its body, so is it valuable.

9. Like poultry, the best breeding rabbits are those kindled in March. The doe will breed at the age of six months; and the time of her going with young is thirty days. The buck and doe are on no account to be left together; but their *union* having been successful, the buck must be directly withdrawn, and the doe tried again in three days, and if she has *kindled* she will refuse him. Some days before bringing forth, hay is to be given to the doe, to assist in making her bed, with the fur which instinct instructs her to tear from her body for that purpose. Biting the litter is the first sign of pregnancy; at this time she will be seen sitting on her haunches tearing off the fur; and on the hay being given she will with her teeth shorten and adapt it to her purpose.

10. They generally bring forth from five to ten; and it is profitable to destroy the weak or sickly ones, if more than five, as that number of healthy full grown rabbits are worth more than ten of an opposite description, and the mother will be far less exhausted; and she will be ready for the buck again at the end of six or seven weeks, when the young may be separated from her and weaned. Much care should be taken that the doe, after she has kindled, should not be approached by the buck or any other rabbit; because if she is harassed about, being of a delicate nature, she will cast her young before her time. If the doe is weakly on her bringing forth, some warm fresh grains, a malt mash, scalded fine pollard or barley meal will warm and comfort her.

11. Due attention must also be given against sudden frost or cold, and particularly damp air; and with the best hay, corn, vegetables, and other food and attention, rabbits may be bred throughout the winter with nearly the same success as in summer. However, they are so productive that one might be satisfied with five litters during the warmest part of the year, giving the doe rest during the months of December, January, and February; as five litters, on a low calculation of five each time, would produce annually twenty-five, which is equal to one thousand from the small stock of forty does. They are seldom good breeders after the fifth year; the buck is fit for use at six months, and is in perfection from one to three years.

12. *Food.*—The art of feeding rabbits with safety and advantage, is to let the principal part of their food be dry and substantial; avoiding weeds and the refuse of vegetables, as such food is too watery and scouring, and can never be an object while the nutritious productions of the fields may be obtained in plenty, and will return a much greater profit. Though rabbits may be kept and fattened upon roots, green vegetables, and hay, yet they will pay for corn, such as oats, peas, pollard, or shorts, and buckwheat; and will always thrive well with an equal allowance of vegetables, such as carrots, potatoes, raw, baked, or steamed; clover and meadow hay, tares, lucerne, cabbage, lettuce, corn-leaves, apples, turnips, parsnips and beets, in fact what they will *not* eat; summer supplies them with a variety of food that may be gathered every where; during winter give them small branches of the green cedar, and small birch and apple brush, for them to eat the bark.

13. The better the food, the greater the weight, quality and profit, which is the case with all animals. Many fatten with grains and wheat bran, (the husk of wheat sifted from the flour,) but the rabbits' flesh being dry, a small allowance of fresh greens is desirable. They are in perfection for feeding from the fourth or fifth month; and it requires two months to make them completely fat and fleshy; but they, like sheep, may be over fattened. Castrated rabbits may be fattened to the weight of upwards of ten pounds; and it is successfully practised in Sussex, where capons are so numerously reared. The operation is performed at six weeks old.

14. In killing full grown rabbits, after the usual stroke upon the neck, the throat should be cut upwards towards the jaw with a small pointed knife, in order that the blood may be discharged, which would otherwise settle in the head or neck. Its flesh is esteemed equally digestible as that of fowls, and of course equally proper for the table of invalids; they are best when young, or middle-aged, and most in season in winter.

15 The rabbit is a caressing animal, and equally fond with the cat of its head being stroked; and not altogether destitute of courage, having been

frequently known to attack the largest cats, and to tear their hair off by the mouth full. The only proper way of holding them is by their ears.

16. *Diseases.*—With due care and regular attention, the rabbit is not liable to disease or sickness, but should any disorder attack them, it is best to kill them. If they become pot-bellied from being fed on watery food, cure: by giving good dry hay and corn, ground malt or peas, or any substantial or absorbent food. Their liver complaints are incurable, and such, if put up to fatten, must not be kept after they have attained a moderate degree of fatness, as they are liable to die suddenly. If dry substantial food is always within their reach, they will seldom require medicinal care.

From the Farmers' Cabinet.

RAISE MORE POULTRY.

Since the time that Esop wrote the history of the country maid and the milk-pail, poultry and eggs have not sold for a better price, or at a greater profit, than they have within these few years. This is believed to have grown out of the immense amount of travelling, which has been increased and promoted by the fleetness and cheapness of railroad cars and steamboats. But whatever may be the cause of it, it is our interest to sell an abundance of eggs and poultry, so long as we can get a good profit by it. I was pleased with the suggestion made by your correspondent Q., in the last number of the Cabinet, for feeding poultry with boiled potatoes, inasmuch as it is a cheap food, and may be always at hand. A farmer near Liverpool, England, keeps a large stock of poultry of various kinds in the same enclosure, with singular success. He has nearly an acre of land enclosed, with a close fence, about seven feet high. Within this enclosure are put up sheds for the different kinds of poultry, to secure them well from the rain, which is of great importance. There is a small stream of water which passes through the lot, to which they all have access, and they are regularly fed, three times a-day, with boiled potatoes, which is their only food, excepting what grass, insects, and worms, they pick up in their movements through the lot.

All young poultry require to be kept dry, and most old ones are the better for it, and it is said that young turkeys, during their tender age, are the better for having a small quantity of red pepper occasionally mixed with their food, to stimulate their digestive organs to greater activity when they gormandize too much.

The practice of cutting up chives, garlic, or onion-tops, and mixing them occasionally with the food of young poultry, is well known to most good housewives, and is thought to be very serviceable in promoting their health. K.

Pequea, Lancaster Co. Pa. June 25, 1838.

ADVICE TO FARMERS.

Judge Buel says, "It has been found that the best and most butter is obtained when the cream is about the temperature of 55 degrees—and if the temperature is over 60 degrees the quality is inferior and quantity diminished. Hence every dairy should have a thermometer."

From the Western Carolinian.

THE FARMER.

Happiness seems to have fixed her seat in rural scenes. The spacious hall, the splendid equipage, and pomp of courts, do not soothe and entertain the mind of man in any degree, like the verdant plain, the enamelled mead, the fragrant grove, melodious birds, the sports of beasts, the azure sky, and the starry heavens.

It is undoubtedly a fact, that in proportion to our population too many leave the occupation of agriculture for other employment. If this arises from its being considered that the employments of the farmer are not respectable, it is a great mistake. Every thing is honorable which is useful and virtuous. This is an employment instituted by God himself, and by him particularly owned and blest. It is that on which every thing depends. True it is laborious; but then labor brings health, is the foundation of the farmer, is the condition of independence; his little dominion is his own, his comforts are his own, and he is not at the mercy of the public whim and caprice. It is not necessarily the case, in this happy country especially, that the farmer must be a stupid, ignorant man. He is taught in his youth the first rudiment of education, and has many spare hours to read. In the heat of the summer's noon, and by the long winter evening's fire, he has much time for his books, and in this country they are placed within the reach of all.

From the Watertown (N. Y.) Standard.

IMPORTANT EXPERIMENT IN PLANTING CORN.

A few weeks since we published a communication from a correspondent, giving the results of an experiment in planting corn, by Hart Massey, esq. of this village. Mr. Massey called upon us on Saturday last to correct an important error in said communication, and invited us personally to examine said field, which we accordingly did, and now give the results of our observation.

Mr. Massey took of the seed corn with which he planted the field, a small quantity, and soaked it in a solution of sal nitre, commonly called saltpetre, and planted five rows with the seeds thus prepared. The remainder of the field, we believe, was planted by the same individual. Now for the result. The five rows planted with corn prepared with saltpetre, will yield more than twenty-five rows planted without the preparation. The five rows were untouched by the worms, while the remainder of the field suffered severely by their depredations. We should judge that not one kernel saturated by saltpetre was touched, while almost every hill in the adjoining rows suffered severely. No one who will examine the field can doubt the efficacy of the preparation. He will be astonished at the striking difference between the five rows and the remainder of the field.

Here is a simple fact, which if seasonably and generally known would have saved many thousands of dollars to the farmers of this county alone in the article of corn. It is a fact, which should be universally known, and is, in all probability, one of the greatest discoveries of modern times in the neglected science of agriculture. At all events, the experiment should be extensively tested, as the results are deemed certain, while the expense is comparatively nothing.

Mr. M. also stated the result of another experiment tried upon one of his apple-trees last spring. It is a fine, thrifty, healthy tree, about 25 or 30 years old, but has never, in any one year, produced over about two bushels of apples; while in blossom last spring, he ascended the tree and sprinkled plaster freely on the blossoms, and the result is, that it will this season bear 20 bushels of apples. Now if the plaster will prevent blast, it is a discovery of great importance. Mr. M. was led to make the experiment by reading an account of trees adjoining a meadow where plaster had been sown at the time there was a light breeze in the direction of the orchard, the trees contiguous to the meadow bearing well, while the others produced no fruit.

ON THE GREAT RAFT IN RED RIVER.

To the Editor of the Farmers' Register.

* * * * * * * *

I do not possess as accurate information about the great raft in Red river as I ought, to justify as minute a description of it as you wish; but I give the best I have, only warranting it to be substantially correct.

The raft is an obstruction of fallen trees and logs, that have entirely reached from one bank of the river to the other, and firmly fixed in its bottom and sides, and has, with intervals of unobstructed or open river, occupied a space of from 130 to 150 miles in extent. Over this space, in a thousand places, a foot passenger can cross without wetting his feet, and see the slow current below him. About one half the river has been filled with alluvion, on these logs, which has given growth to a dense mass of cotton-wood and willow trees, of various sizes, forming a shelving bank, that will never be removed by the current. The future river will be the inroads made by the engineer, and the current of the stream, on the other bank of the river. The great business of the engineer has been to enable the stream to clear itself out. When the country was first occupied by the whites, the raft was about 150 miles above Natchitoches, and about 20 or 30 miles below the bayon or outlet of Lake Bestineau. At this bayon Capt. H. Shreeve, the U. States' engineer, commenced his operations, about five years ago. The raft once formed, of course stopped all the drift-wood, and increased from 1 to 3 miles a-year, according to the number and heights of the annual freshets, and decreased below about half that space. The growth of a rich swamp being generally sappy woods, were rapid in their decay, subjected as they were, by their position, to be alternately wet and dry; and as they decayed, were loosened and carried off by the current, which made it again an open river. This accession above and secession below have perhaps been going on for ages. The unequivocal remains of the raft, in low stages of water, may be seen in numerous places several hundred miles below where it lately was, and some nearly as low as the disemboguement into the Mississippi. The original formation of the raft may probably be attributed to one of the following causes. The Red river is a stream of immense length and great depth, compared with its width, and is very crooked; its s[...] a very fine sand, with a pure vegetable deposit; [...] length exceeds 1500 miles; its depth averag[...] from 15 to 20 feet, and its width about 200 yar[...] as near as my eye-sight enabled me to judg[...] The swamp shows that the river has frequen[...] changed its channel; and this, at some distant dat[...] may have occurred on the rising of some great fres[...] et making a new channel, which has been choke[...] by the falling in of the timber from both sides, coupled with the drift-wood. Once stopped, all the other consequences are very natural. Another cause, and more probable, may be that the Mississippi, receiving its waters from points more distant and much higher up the country, raises it higher, and backs the water up all its tributaries below the Missouri from 20 to 50 miles. I have passed up and down the Red river when it was so backed up, and showed little or no current. The drift-wood must accumulate at these places in immense quantities; and you can easily suppose how probable it would be for 2 or 3 miles of drift-logs, with their roots and limbs to them, intersecting each other, all seeking to pass out at the same time, as the Mississippi should fall, would reach from side to side of the river and lodge, and the press of the upper logs would make the jam complete. I give the above as the probable causes. They are entitled to no more respect than as they may be correct deductions from the facts above-stated. The raft once removed will never form again where the river is open to its proper width. If it should be, by the back-water of the Mississippi, it will be at a point below where 50,000 bags of cotton now have to pass to market, and will be removed before it can have time to form into any material obstruction, within the upper part of the raft, where the river has no one current half its proper width, in its present state of clearing itself. Such an event is very probable, and the engineer, two years ago, communicated to the war department such probability, and a steamer has been built, to remain a year or two, till the river clears itself to its proper width.

The effects produced by the stoppage of the usual passage of so large a body of water, and that swelled to more than double the amount by the periodical annual freshets, as was to be expected, have been very great. Immense bodies of fertile lands have been overflowed, large lakes have been formed, (now navigated by steamboats,) such as Lakes Bestineau and Caddo, or Soda; and large rivers or outlets created, which, so soon as the river is compelled by man to return to its accustomed channel, and shall have worked out a depth equal to its depth above and below, will be restored very much to their former condition. I think it probable that in ten years, fine crops of cotton and corn will grow on the bottom of those lakes, now the tract of the steamboats, and fifty thousand acres of the richest land will be redeemed from nearly a perpetual overflow. The raft region, for the space of near 500 miles, presents generally two streams or outlets and inlets, as the upper bayous that create lake Bestineau on the east, and lake Caddo on the west. Where the Caddo waters, come in, just above Shreeveport, the river is large and fine, but soon expands into the Bayon Pere; and where that comes in, it again expands into the Bondieu, again coming in near Alexandria; and they each carry as much water as the Red river. The Bondieu is now the river of navigation, carrying two-thirds of the water, and threatens in a few years to throw a bar across the Red river, and make Natchitoches only accessible in high stages of water. The steamers now go to Shreeveport, 100 miles within the late raft, in stages of water that compel them to leave their freight for Natchitoches four miles above the town. Such have been the effects of the raft, and some such as I have ventured to anticipate, will be the effect of its removal. The river, both above and below the raft region, has but one stream, and that a noble one; and it has been the object of the engineer who directs the work, to make it but one through the raft.

The modes of removal have been as various as the differences in the situation of things. The object has been to do more than to enable that powerful agent, the current, to clear itself out; and so formidable have been the obstacles, and so various in their character, that it has required all the skill of the engineer, with the aid of strong natural talents, and the possession of a great share of that uncommon quality, called common sense, to overcome them. Such a man the government has found in Capt. Shreeve. One of the most usual modes of work has been to place the laborers on the raft, who saw all key logs, or such as seemed most to confine others to their places; and when so prepared for dismemberment by their previous cuts, the cables are fixed to them by iron wedges at their ends, driven into the logs, and the steam is applied, and large masses are pulled away. These logs are turned over to other boats in the rear, that cut off the stump-ends, and where the branches put out; and the logs, so deprived of roots and branches, float on the surface without the danger of tangling or holding on to each other, and are passed out by the current, in times of high water, through the Mississippi into the ocean. The snag-boat comes in the rear, removing the snags or other logs too firmly fixed for the first pull, and runs directly on the snag, and where it does not break out, it is fastened to the chain and pulled out with ease.* The power is, perhaps, the greatest now used in America, and can in a few minutes uproot the very largest trees, and drag them from their residence. The diameter of the wire of the chain is $1\frac{1}{4}$ inches, and each link weighs upwards of 15 pounds; and the power is such that the tree must come, or the chain will snap. It has been equal, so far, to remove every thing to which it has been applied. A cotton wood tree, 40 feet long, by 5 feet diameter at the but, three or four feet under the mud, has been one, if not the greatest, of the applications of its power that I have seen.

The larger portion of the logs are used to fill up all the material outlets of the main stream, and the old river, whenever a new one has been made by a cut-off. There is no danger of their being returned by high-water into the main river again, as it is the uniform operation of the master stream to fill up the mouths of all its outlets whenever the current in them is materially checked.

Another usual mode of work is to cut all the trees from islands and wearing points of the banks, and remove the wood; and the stream so aided will remove the earth.

Another mode is to cut off, occasionally, large bends in the river, whereby many miles of raft have been saved the clearing by a cut of 100 yards. When the freshet enters these cuts or canals, the sides fall in, and dissolve like sugar; and 24 hours gives you a new river. These cut-offs save labor, improve the navigation, by increasing the current, and furnish a convenient depository for drift-wood. These, with occasionally making dams across large rivers, where you could not otherwise materially check the current, constitute the principal modes of applying labor.

The operations of the first year cleared upwards of 100 miles of the raft, in consequence, as I have said before, of the logs being very much decayed, and to that distance, that is to Shreeveport, there has been for some years, and now is, an excellent steamboat navigation. The difficulties above that place have been very great indeed, and have occupied all the time since, till May last, when they were removed, so as to give passage to steamboats 250 miles above the raft to Fulton, Fort Towson,&c. About half a dozen boats have been plying regularly between New Orleans and these places since that time. A steamboat, with a few hands, will have to remain in the raft for a year or two, to prevent the creation of new obstructions from the banks falling in, while the stream is working out a sufficient passage for itself. When this is done, the river, like all others, will take care of itself, and will furnish a safe and convenient high road to market of the products of what, from all I have seen, I would say, is the finest cotton country in the United States.

A Planter.

A FIRST TRIAL OF SILK CULTURE.(*a*)

To the Editor of the Farmers' Register.

Diamond Grove P. O. Brunswick, Va.
Aug. 11, 1838.

I promised to give you an account of an experiment I made, last spring, in the culture of silk. I shall not attempt it in detail, but merely give the result. The eggs commenced hatching about the 1st of April; and having then but little confidence that the placing them on ice would retard the process, and the cocoonery I was then building not being ready for the reception of the worms, I was forced to crowd 50 or 60,000 on two shelves for a week; instead of which every day's hatching should have been kept separate and distinct. So many different ages having been mixed up together, made the labor much greater about the time of spinning.(*b*) If possible, all on a shelf should spin at the same time. I determined, however, to try an experiment of about 30,000 eggs, by putting them in a tin box, and placing them directly on the ice, which was done after many had hatched. They were kept on the ice ten days, and then taken out, and in a few days they hatched out fully as well as the first. I supposed I fed in all 90,000 worms, and not having a sufficiency

---

* The snag-boat is a steamboat, the invention of Capt. Shreeve, open at the bow down to the water's edge, with two large vertical wheels on the same shaft, over which an immense chain is passed, and this lever operated on by the water wheel shaft. The snags are run into this aperture at the bow, and so made fast for the levers to act on.

of the *morus multicaulis*, or Chinese mulberry leaf, at that time, I made use, in part, of leaves from our native black mulberry.* The worms remained quite healthy, until I supposed eight-tenths had spun excellent cocoons. The leaves of the common mulberry became scarce. I had to send three miles for them; and the weather being then very warm, I found it impossible to get them to the cocoonry before they became heated and dark, which caused disease amongst the remnant fed with the native mulberry. Some died; and those that spun the cocoons were not as perfect as they should have been. Those fed with the Chinese mulberry leaf remained healthy, although the shelves were within a few feet of the diseased ones. The nursery of the Chinese mulberry being convenient, the leaves were used fresh from the tree, or placed in the cellar before they became warm, and sometimes remained two or three days in good order. I think that worms fed with the leaves of the Chinese mulberry, are not as subject to disease as those fed from our native trees. If fed with the former, they consume every part of it; but when the leaves of the latter are used, they refuse a large portion, which, if allowed to remain on the shelves, will certainly produce disease.(*c*) The labor saved in gathering the leaves of the Chinese mulberry being so considerable, I have no doubt it will supersede the use of all others. Some have calculated this saving of labor at nine-tenths, and, I think, are not far out. I have weighed 150 lbs. of cocoons, which I am now reeling. One of the hands gets half a pound of raw silk per day. The reeling is done on a reel I had built at home, after a model I purchased last summer, in Hartford, Connecticut, for five dollars; and I think they can be made for three dollars. I have no doubt they are equal to the patent reels, so much puffed at the north. I can see but little difference in the strength of the silk made from the two different kinds of mulberry; except that made with the Chinese has a lustre, which gives it a superiority. I made but one crop this season. I have no doubt that three crops can be made; and I should have attempted it, if I could have procured the eggs. The hands I had employed were double the number necessary. My object was to instruct them in the business, so as to be ready for a much larger crop, another year. One of the hands, after attending the worms two weeks, could have managed half I fed in the usual way. It is quite a mistaken notion with some, that slave labor will not answer in the culture of silk. I had some white hands employed; but I also had some blacks, who were little inferior to the best white laborers, and are now reeling excellent silk. One of the black hands, now only eight years old, I found very useful in feeding worms, and can now reel well. I have no doubt, much of the labor I bestowed was unnecessary, as the business was entirely new to all employed. The cocoonry I had built is 40 feet by 24, and 16 feet pitch, well fitted up with shelves, on the most approved northern plan. The house should be well ventilated, to admit the air freely through, or the worms will certainly become diseased. I have no doubt that a house built of logs is equal to any that can be fitted up; and the barns now used for tobacco can easily be converted into cocoonries. I have 30,000 *morus multicaulis* or Chinese mulberry trees, and a nursery that will afford from 80,000 to 100,000 cuttings this fall. Should the silk crop fail, (for which I have no fears, being so fairly tested,) I would certainly plant an orchard of the Chinese mulberry trees, for the purpose of feeding stock. I find both horses and cattle remarkably fond of the leaf, and I think we have no coarse forage possessing more nutriment. I think an acre of land planted in mulberry trees, will produce as much in weight, (the leaves being easily cured,) as our best grass meadows, in the southern and middle counties of Virginia. The trees will yield several crops of leaves in one year.

I commenced, like most others, with too great a number of worms, before I had a sufficient quantity of leaves, and but little knowledge of the business. From 5,000 to 10,000 are fully sufficient to commence with. The worms, in the 4th and 5th age, eat an incredible quantity of leaves; and if they are not fed plentifully, it prolongs the time of spinning, and, therefore, increases the labor. One of my neighbors fed but few worms, and they commenced spinning in 25 days; while mine were 40 days before a cocoon was formed.(*d*) Taking every thing into consideration, I think the crop a fair one, and am willing to try three crops next year.(*e*)

I shall have more trees than will be necessary to carry on the business next year, and am willing to dispose of part of my stock.

THOMAS HICKS.

* *Morus rubra.*—ED.

Notes, by the Editor.

(*a*) It is with much gratification that we have received, and present to our readers, this account of a first, and therefore imperfect, experiment of silk-culture in Virginia. The writer's locality is precisely that which offers the strongest inducements, and promises the highest profits, for this business; and we feel assured that he will so correct his first (and always inevitable) mistakes, as to be able to prove, practically and satisfactorily, the soundness of the position which we have long ago assumed, and again recently asserted, that whatever may be the profits of silk-culture in the northern states, they may be far surpassed in Virginia, by applying equal skill, care, and industry, to the superior advantages of our better climate, and cheaper land and labor. The interest which we feel in this subject, and the value attached to the experiment and labors of our correspondent, will induce the making some remarks and strictures on parts of his communication; which, for convenience, will be appended in the form of notes to the passages referred to.

(*b*) The keeping together worms of different times of hatching was a very great error, and must have caused loss, and injury to the worms, in all their different "ages," or times of moulting, by the difference of time in which they were commenced and ended, as well as the injury found at the time of spinning.

(*c*) The bad condition of the leaves of the native mulberry, used for the latter worms, was sufficient to account for their being less healthy food, and producing inferior silk, to the Chinese. It will require a much more careful and fair experiment than this, to establish the fact, that worms may not be kept as healthy, and e to produce as much, and perhaps as good silk, on native mulberry, as on the Chinese; though there still enough of superior advantages in the latter , in other respects.

(d) The prolongation of the time before the worms begin to spin, whether caused by scant feeding, want of warmth, or any thing else, is doubtless attended by loss in more respects than the mere additional food thereby required, and the labor of giving it. The health and vigor of the insects must suffer, and the quantity of silk finally produced by each will be less. A comparison of his cocoons which were not formed before the worms were 40 days old, with those of his neighbor, which were begun at 25 days old, would probably have shown the superiority of the latter.

(e) We fear that the attempt at three, or even two crops of cocoons in a year, will not succeed, except to the great injury and destruction of our correspondent's young mulberry trees. At least, we would advise his making, at first, but a small experiment of double or triple crops; and the second or third feedings to be confined to a certain portion of his trees, so that the degree of injury may be observed, and properly estimated.

From the Farmer and Gardener.

COB-MEAL AND COB-MILLS.

A friend and correspondent in Ohio has requested some information as to the value of cobs ground with the corn, and the cheapest and best mill for grinding them together.

That a very great saving is effected in feeding animals by grinding their food does not admit of a doubt; and the explanation of the fact, as given by Raspail and Dutrochet, is perfectly satisfactory. It is also certain that when nutritive matter is properly divided and incorporated with some substance suitable for the action and distention of the stomach, that a much less quantity will suffice, and the animal be in equally good condition.

It is on this principle that the English custom of substituting cut straw for hay in feeding with grain, a saving of one-half of the expense being made by feeding with cut straw and ground grain, over feeding with hay and unground grain, according to the old mode. Neither the straw, or the cob contain any great amount of nutriment in themselves, but they assist the digestive functions, and render the accompanying nutriment more available. The cob however has much the advantage of straw in every respect; and experience shows that those lose much who waste this important part of the corn crop.

Some interesting experiments have been recorded, in the N. E. Farmer, on the subject of fattening animals on corn and cob-meal. The Rev. Mr. Perley in describing his method of using the food says:—

"I have for several years practised having my corn and cobs ground together; breaking the cobs fine by pounding, and grinding one peck of corn with a bushel of the cobs. Meal made of this composition, I scalded, and made about as thick as common hasty pudding, or mixed about one peck of the meal with about three pecks of boiled potatoes, thickened to the consistency of pudding. There were no hogs in the neighborhood grew so fast, or were fit to kill sooner in autumn."

In the Massachusetts Agricultural Repository is a communication from Mr. Rice of Shrewsbury, in which he says:

"The very best provender I have ever used for fattening cattle, is corn and cobs, ground together. The reason I consider the cob useful is, it swells in the creature, and keeps him in good order; in no one instance since I have fed with this meal, have my cattle been out of order by being cloyed, or scouring; they are at all times regular; but when I formerly fed with clear Indian, or oats and Indian, these difficulties frequently occurred, and they would lose as much in two or three days, as they would gain in a week. The second year that I made use of this kind of provender, I thought I would try an experiment, by feeding one ox with corn and oats ground, the other with corn and cobs, having one yoke oxen so equally matched that no one who viewed them, appeared satisfied which was best. The cob is computed to make a little more than one-third, therefore I mixed the other with one-third oats, which was my former mode. I gave each ox an equal quantity at a time, except that the one which had corn and oats some days became dainty, and would not eat his allowance; while the one fed with cob-meal kept on his regular course. When taken to market and slaughtered, the oxen weighed 28 hundred and a half, the one fed on corn and oats had 162 lbs. of tallow, and weighed about half a hundred more. The one fed on cob-meal had 163 lbs. of tallow, and the butcher pronounced his meat half a dollar in the hundred better than that of the other."

In the third vol. of the Philadelphia Society for promoting Agriculture, is an excellent paper by Dr. Mease, in which the utility of grinding the cobs with the corn is clearly shown, both from analogy and actual experiment. And we believe that wherever it has been tried, or wherever the means of grinding can be had, it has been approved, and will be found of great value.

So far as we are acquainted, cobs after being broken, are ground in the common millstones with the corn. The same machinery used for grinding plaster of Paris or gypsum, has been found efficacious for grinding cob-meal; the plaster cracker reducing the cob sufficiently for the action of the stones. Mr. Buckminster, speaking of machinery for this purpose, says,—"for making cob-meal we placed in our mill a pair of large stones, cut the eye of the runner 12 inches at top, and 14 or 15 inches at bottom, and bosomed it out large, as we term it. In this manner it answers every purpose for grinding and cracking corn in the ear."

The cast iron bark mill has been used for cracking cobs to some extent, and where a mill is convenient to grind the cobs and corn after cracking, would answer a good purpose; and we can see no reason why one constructed on the same principle, and like those worked by a horse or water power, might not be constructed to reduce the cobs and corn sufficiently fine to answer instead of the ordinary process of grinding. It must be remembered, however, that the goodness of cob meal must always in a great measure be dependent on its fineness. Where it is an object to provide a mill of this kind, any farmer who has a horse-power thrashing machine, may with little expense procure ordinary millstones, and by attaching a cracker as for a plaster mill, or arranging the stones themselves as recommended by Mr. Buckminster, have a mill not only useful for grinding cobs but all the grain he intends for feeding. As the power required would be lessened as the velocity was decreased, two horses would run a pair of millstones, it is believed, with as much ease as four do the larger thrashing machines.

From the Franklin (Ky.) Farmer.)

MANAGEMENT AND DISEASES OF HOGS.

To Chilton Allan, president of the Kentucky State Agricultural Society.

I have seen in a late number of the Franklin Farmer, your circular address, calling upon the friends of improvement for essays upon a number of important subjects relating to the agricultural interests and pursuits of our state. Approving heartily the noble objects of the State Society, I read your address with great satisfaction; and I cannot but believe, that the action of the Society will bring about the most gratifying results in improving the science of agriculture, and hence the condition of the husbandman: for I cannot doubt, that every one who desires improvement himself and who would derive useful information from others will hold himself bound to contribute something to the general stock of knowledge. There are few intelligent farmers who do not know something unknown to others, and it is by an interchange of sentiment and opinion, as well as of experience and practice, that the farmers of the country will be able to see and reject the errors of their husbandry and adopt those modes instead which lead to improvement and success. In this view, I offer an humble tribute, which at least has the merit of a well meant design of benefiting others in some respects.

The commencement of our prosperity may be dated from the period when our agriculturists turned their attention to the raising of stock for export; and as the consumption and demand have increased in a ratio with the increase of population and wants of the people of the United States, the business has become a source of wealth to Kentucky. And no where has the improvement of stock been so great and so general, nor more zeal and perseverance manifested to procure the breeds of horses, asses, cattle, sheep and hogs. In enumerating these descriptions of stock, the last is not the least important in bringing wealth to the state, and should be looked to with a fostering care and attention.

Under this belief, I humbly submit to the public through you, the following observations on the management of hogs, with some remarks on some of their diseases.

In giving my views on these subjects, I deem it important to state some of the various ways of raising, feeding and fattening hogs in different sections of the country, which, according to circumstances, soil and climate, will differ; and conclude with my views as to the best mode to be adopted by the farmers of Kentucky under her peculiar circumstances. In Europe and many parts of the United States, hogs are indispensably kept in pens or sties, and as the numbers raised are comparatively small, there is no great expense attending the manner of feeding them; indeed this is the most economical, cheap and convenient method of fattening that could be adopted in any country where the number fed is small. In some of the New England States large buildings have been erected for raising and fattening hogs on an extensive scale, fed almost exclusively on vegatables produced on a few acres of land, which gives a profit of 50 per cent. more than any other way in which the products of the land could be disposed of. On this extensive scale, the business is unconnected with any other, having for its object the raising and fattening of hogs alone, for it requires the most strict attention which daily habit and the most scrutinizing observation, in time reduced to a perfect system, can give. It was ascertained to a fraction, what each hog would eat at a meal, which was measured out to him three times a day, the quantity according to age, allowing six of the same age to occupy a sty, which was regularly littered and cleaned out once a day. The amount of vegetables required per day, and the necessity of the different varieties coming on in due season, would require great attention. At the first view of the subject, we would conclude that a piggery conducted in like manner in Kentucky, would be equally profitable. But not so—there would be this difference:—The price of pork and lard in Boston is more than 50 per cent. higher than in Louisville: and the profit accruing from the superabundance of manure, which is worth from two to three dollars a load in the New England States, will amount to a large sum, which with us would be excluded from the estimate, as it will bring nothing here on sale, though useful to the land on which the hogs are fattened. In 200 hogs annually sold, these causes would produce a difference of perhaps three thousand dollars in favor of the New England piggery.

Say 200 hogs at 200 lbs. each, 40,000 lbs. pork at 10 cents in Boston,	$4,000
For their manure,	1,000
	$5,000
40,000 lbs. pork at Louisville, at 5 cents.	2,000
Leaving a difference in favor of the New England piggery,	3,000

In no way could an extensive piggery be made profitable to us but by being connected with a distillery. The expenses would then be much lessened; for it would require but a few vegetables or little meal added to the slop of the distillery to make the swill highly nutritive. They might be put to graze in the summer and swill given them occasionally and again put in the fall.

The manner of feeding and fattening hogs now generally adopted in this state, seems to me to be well calculated for our method of cultivation. Taking into consideration the products and the great number of hogs fatted for other markets, together with a great number of beef cattle annually grazed and fed, the system is complete. In winter, they are amply supplied with food from the refused corn and pudding of the cattle—two or three hogs to each head of cattle finding thus abundant sustenance. In the spring, when the cattle are no longer fed, the hogs are put on the exuberant clover field, which was sown for the double purpose of enriching the land and supplying rich food for their cattle and hogs. In due time, when the clover becomes hard, and unfit for the hogs, it is given up to the earth, and they are removed to the rye fields, there to fatten and complete another system of manuring, so admirably adapted to our lands and our wants. So soon as the rye field is consumed, the corn field is ready to receive them,* and in due time they are ready for market, leaving the fields and pastures richer than they were.

Although this arrangement is good for feeding and fattening, yet there are other important matters in relation to their raising and health, which in no wise should be neglected. Experience has taught me, that no matter how many pigs a sow has over six, they should be reduced to that number, always retaining the large and healthy ones; for I can, and will demonstrate, that six pigs will make more pork at 12 or 18 months old, than eight would of the same litter—and eight will make more than ten. Give to the six the food which you would give the eight or ten, and you will find in the result the truth of my statement proven. It is essential that pigs be kept fat while sucking, and to have them so, six is a better number than eight or ten. At weaning time or when sixty days old, the time when the sows decline in milk, particular attention should be paid to the pigs, having them regularly fed either with corn or swill, for at this juncture, they are unaccustomed to *root for themselves*, and will rapidly lose their flesh and their health, and their growth will be retarded, if left to shift for themselves. If they are kept fat during the fall, when provisions are plenty and cheap, they will keep thrifty and well through the winter, on very moderate feeding; but I prefer liberal feeding throughout. The food is by no means thrown away, as you will have more pork and not any more corn consumed in the end.

Hogs should be kept free from diseases; particularly the disease of worms, which is very pernicious and a constant attendant on poor hogs. Liberal feeding at all times, is the best preventive, *but when it is not in the crib*, brimstone, spirits of turpentine, or tar mixed with their food will remedy the evil. All hogs are more or less subject to worms; but some are so overcharged, that their intestines are literally filled with them, and unless they are extirpated, it is throwing away corn to feed them, for in this condition it is almost impossible to fatten them; they will consume twice as much as a hog will not troubled with them, as the nutritious juices are taken up by the worms, and their fetid excrement is all that is left as a miserable substitute for sustenance.

The most fatal disease of hogs is the swelled throat or quinsy. This too, is easily prevented. I have long been of the opinion that it proceeds from indigestion, caused by feeding on hard grasses or clover in their declining state; and my successful practice as a preventive for the last eight years is a strong confirmation. Yet it matters not concerning the cause, provided there is a remedy. The disease in the last stage, is highly inflammatory, but at no time infectious. It is an accumulation of matter formed between the glands of the jowl, which continues to inflame till the hog dies of suffocation. The disease may be cured before and after the matter begins to form; but as it may be more satisfactory to state my experience and knowledge on the subject, I will give an instance as coming under my observation, and conclude with my practice as a cure and preventive. In 1830, I discovered the disease among my hogs by the death of one of my fattest. As soon as possible, I had them removed from the clover field, and put in a spacious pen, where they were fed with as much corn as they would eat after it was glazed with tar and as much ashes put on as would adhere to the grains. They still continued to die till I lost to the number of fifteen. This great number dying out of eighty, caused me to doubt the efficacy of the remedy, or that the disease was too rapid for its effect. Shortly after, they were put up to fatten, which they did very readily, and I was left in doubts as to the effect of the medicine, until the day I butchered, when I found lumps of coagulated matter in the jowls of many, about the size of a hazelnut or larger, without any signs of inflammation around them. I then came to the conclusion that they would have died had it not been for the remedy applied, and that the disease of those that died had advanced too far to be cured by any remedy. Observing that hogs kept in sties never had the quinsy, I attributed it to the wholesome quality of food they ate, and on the contrary, the cause of their having it out of sties, to the pernicious qualities of hard dry grasses. Since 1830, I have invariably given my hogs, during the spring and summer months when grazing, slop or swill once a week or oftener, consisting of kitchen slop with cooked vegetables of various kinds, apples, &c., with bran or a little meal, mashed to a paste, salted and cooled off by adding a quantity of water, and occasionally brimstone or saltpetre. Since the above date, my attention has been directed to the raising and fattening of hogs on the products of a small farm, and I have never yet lost a hog by this disease, nor in my recollection by any other. My opinion is still further supported as to the cause of the swelled throat, by its being less frequent since the practice lately adopted in putting the hogs to graze when the clover is young and tender, and taking them off when it is old and tough.

Every body knows that the young and old hogs should be kept apart in winter; and yet how shamefully this important matter is neglected by many. Young and old, great and small are crowded together, day and night, mashing and smothering; and yet many will look on with heedless regard at the great destruction of their young stock, without separating them. When young and old are fed together, the old will always get more than their share, thereby the young become poor and diseased, making little or no progress in growth.

* We presume our writer does not intend to be understood, that the hogs are turned into the corn field; for though this practice may be adopted by some, the more general custom is to put them in a large pen adjoining, into which the corn is thrown. If the corn is not sufficiently ripe when the rye is consumed, old corn is fed to the hogs; and indeed, the feeders generally, we believe, prefer beginning to feed them on old corn after they are put up—introducing the new rather cautiously and gradually.—*Ed. F. Farmer.*

The breed of hogs best calculated for our general purpose is yet to be ascertained. Within a few years, great exertions have been made, at considerable expense, to procure the best breeds, but whether any of them answer our expectations, I think very doubtful. The breeds imported here, were improvements made to suit the purposes of others under different circumstances, different soil and climate, different food and management, and under a different method of disposing of the pork, and according to our present mode of farming; thus differing from the methods abroad, whence these hogs have been brought, and our surplus pork being chiefly driven to the south, I think ultimately they will not do except in the event of the successful completion of the railroad from Lexington to Charleston. Then the smaller and earlier matured hogs, the Byfields, the Berkshires, the Bedfords, &c. will be more profitable than the larger breeds. But should this all-important improvement to the west prove abortive, the hog that will be best calculated for our interests, is yet to be improved by some judicious cross from our present great variety of breeds. The fat varieties, as the Bedford, Berkshire, &c., from their early propensity to fatten, are best for family use and home consumption; but owing to their incapability to travel, they must measurably give way to the longer-legged hog, until the railroad from Lexington to Charleston is complete.

BIRD SMITH,
Member Ky. State Ag. Soc.

From the New England Farmer.

VALUE OF MANURE.—INTERESTING EXPERIMENTS IN FARMING.

James W. Thomson, M. D., Cor. Sec. Ag. Society:

Although I am not what might be called a practical farmer, not having had the time to devote to it that I could have wished, yet having done something in that line for a considerable number of years, I feel a freedom in submitting a few experiments in the raising of produce, which may be improved upon by those better calculated, have more time, and are more devoted to the business of farming than I am. But to proceed to the experiments. Having purchased a small tract of poor land, near Wilmington, Delaware, which was overrun with the daisy, (or Richardson's pink,) and wishing to eradicate that pernicious weed as early as possible, I determined to work the ground hard, by a quick rotation of crops, taking care to lime and manure in proportion. After progressing in this way for a few years, it occurred to me that it might be worth while to ascertain the amount raised, and the value per acre, by the process I had adopted. The first lot of ten acres was treated as follows. In the fall I put on twenty-six loads of barn-yard manure to the acre, spread it evenly, and ploughed it in; after which it was well harrowed,and so left until spring, when it was again twice harrowed; the last time crosswise. It was then run out as near north and south as the field would admit of, and planted in drills, as follows, the first two rows three feet apart, the third row seven feet: the next three feet, and so on, alternately through the field. The object in planting every other row seven feet apart, was that it might have all the advantage of sun and air—but not wishing to loose too much ground, by planting so wide apart, I planted a row of potatoes in each seven foot space—the produce as follows: 500 bushels corn, at 60 cents, $300; and 500 bushels potatoes, sold at 50 cents, (exclusive of small ones,) $250. The corn was cut off in the fall, and shocked in the field, and the ground sown with wheat, (except where the shocks stood,) which was sown in the spring with millet. The produce was 300 bushels wheat, at $1 10 cents, $330. Millet 4 tons, with the seed, worth $16 per ton, $64. Directly after harvest the wheat stubble was ploughed in, and part of the field sown with turnips; the other part with buckwheat, produce 200 bushels buckwheat, which was sold at 50 cents, $100; and 600 bushels turnips, fed to the cattle, say at 25 cents per bushel, $150; in all, $1,194, independent of straw, fodder, &c. The field was then manured, and laid down in wheat, and sown with grass seed. The next experiment was on an adjoining lot of ten and a half acres, manured and tilled as the first, and planted in rows five feet apart one way, and two feet the other, and not exceeding three stalks in the hill, more frequently one and two; produce eighty bushels to the acre, at 75 cents per bushel, $130. The next spring it was ploughed, and planted in potatoes, in rows six feet apart, and manured in the row. I then struck out between the rows of potatoes, and planted corn two feet apart as above —the corn had no manure—produce as follows: 500 bushels sound corn, sold at 80 cents, $400; 1,500 bushels potatoes, sold from 30 to 37½ cents, say 35 cents per bushel, $525. The seasons of 1836 and 1837 were unfavorable for corn with us, and it ripened late. Part of the above field is in with wheat, sown in the fall, with a light dressing of compost—the residue in spring wheat, without manure; both look well. In endeavoring to be as brief as possible, I am apprehensive I have not been sufficiently explicit to be clearly understood. Thy friend,

EDWARD TATNALL.

From the Farmers' Cabinet.

BURDON'S EXCELLENT OINTMENT.

Yellow rosin, the size of a hen's egg, to be melted in an earthen pot over a slow fire, to which add the same quantity of beeswax. When melted, add half a pound of hog's lard, and when that is dissolved add two ounces of honey and half a pound of common turpentine, and keep gently boiling a few minutes, stirring all the time. Take it off the fire, and when it has cooled a little, stir into it two ounces of verdigris finely powdered, then give the whole a few minutes' gentle boiling, and pour through a sieve for use. Nothing takes fire out of a burn or scald in human flesh so soon as this ointment.

I would suggest, that no store in a newly settled district ought to be without a plentiful supply of the above ointment for sale; it is equally good for cuts and bruises and putrefying sores, and might be denominated with propriety, *the universal remedy.*

JAMES PEDDER.

MONTHLY COMMERCIAL REPORT.

A drought of almost unprecedented duration, attended with excessive heat, has prevailed during the greater part of July and the first two weeks in August, and with the exception of a few recent showers, the drought still continues in this part of the country. It has prevailed far and wide—on the Atlantic coast and beyond the mountains—and the crops have suffered co-extensively. That of Indian corn, in some parts of the country, is almost a total failure; while in favorable situations, and where the drought was less severe, a fair crop will be made. Tobacco and cotton require less moisture; but without a long spell of favorable weather, they cannot attain their growth; and, from the failure of the plants early in the season, it is considered certain that the crop of tobacco will be far below an average one.

In those parts of the country where potatoes, flax, and clover are extensively cultivated, the failure of the crops will be severely felt. Our markets are not supplied with the ordinary vegetables of the season. The mills in many places are stopped, and the navigation of our rivers impeded or suspended. Some places have, during this period, been visited with violent storms, and great damage has been sustained.

The price of wheat gradually declined to $1 20 to $1 25; but has advanced recently to $1 30 and $1 35. The crops on tide-water have generally been disposed of; but those in the interior are now partially withheld from market, in consequence of an apprehended deficiency of corn. The last accounts from England exhibited little apprehension as to the result of the wheat crop there. Those from the north-western states represent the wheat crop as very abundant.

The inspections of tobacco in Virginia to 1st inst. amounted to about 39,000 hhds. Since then the supply gradually diminished, and has now nearly ceased. Prices have advanced, and may now be quoted $5 50 to $12 per 100 lbs. The export to Europe proceeds very slowly.

The receipts of cotton, since October last, are 1,804,000 bales, against 1,343,000 to the same period in 1837; and, considering this great increase, prices are well sustained; present quotation 9 to 11 cents. The accounts of the growing crop, in the south-western states, are favorable.

Indian corn has advanced, particularly in the northern markets, where 95 cents to $1 per bushel has been paid. Sales were recently made here at 80 cents.

The banks in the Atlantic states resumed specie payments on the 13th of this month; and no demands were made on them, except for inconsiderable sums required in ordinary transactions. Exchange on New York is at 1 to 1½ per cent. premium; on England 8½. X.

MATERIALS FOR MANURE.

We have spoken of various sources and means of accumulation and manufacture in regard to manures; the barn cellar, the hog sty, the privy, the compost heap, the wash tubs, the sink; in respect to all these matters we have made suggestions, which we hope will be taken in good part by the farmers; and which we are persuaded, if properly attended to, will result in accumulations of valuable manure little dreamt of, when the foundation of the heap was laid, and the first contributions brought to it. The sailors tell us of extensive islands, holding a large population and feasting them in plenty, and reefs stretching themselves for miles in the ocean, and columns of coral rising from the very depths of the sea to its surface, and if the sea could be for a time withdrawn, and their vast height and proportions disclosed to the eye they would be seen casting into the shade even the mighty pyramids of Egypt and the proudest trophies of human art and labor; and all these were the result of the combined and unintermitted toil of very small insects, laboring constantly at these erections by the gradual deposits of minute atoms. These mighty masses show what can be effected by persevering labor, even with most humble instruments and means. The termites or ants of Africa erect large cabins, which, spread out upon extensive plains, look like a vast military encampment. We see constantly upon our own pitch-pine plains, those heaps which the common pismires accumulate; and observe that all this is the product of single atoms brought by single individuals of those minute animals, thousands of whom we destroy at a single footstep. Every part of creation illustrates the extraordinary, immense, and triumphant results of persevering labor. Many of the largest fortunes that have ever been accumulated have arisen from minute savings and deposits.

We hope our illustrations of this homely subject will not be deemed too ambitious. We should be glad to make them as striking and memorable as possible; and we care little for the source whence they are drawn, provided only we can induce the farmers to gather every thing, and to save every thing, which comes in their way, by which the means of enriching their farms may be created or extended. We reiterate the great position, that almost every farm, certainly where its products are consumed on the place, contains the means of maintaining and extending its fertility. Every traveller who visits China, reports the extraordinary condition of the Chinese cultivation; and concludes by stating that the most remarkable and particular attention is paid to the saving of manure. If gold dust, if corn itself, were sprinkled in their streets, they could not be more careful in picking it up and collecting it together, than they are in picking up and collecting whatever may go to the increase of their manure heap.

It is in this matter our farmers fail, perhaps more than in any thing else connected with our agriculture; and this is a failure most essentially affecting their interests. If we would have an improved agriculture, a revolution in our habits must take place here; and when this is effected, and all the manure is provided and prepared, which we can provide and prepare, we have accomplished comparatively half the work. The getting of manure on a farm must be as much matter of study, care, and labor as the getting of crops from that farm.

We are of opinion that on every considerable farm there should be a man employed with a cart and horse or yoke of oxen, whose sole and exclusive business it should be, excepting in some extraordinary emergency, to collect the materials for manure; and to put them in the way of being manufactured. It is not enough for the farmer to say he will do this at his leisure; this shall be the business of odd times; he will attend to this when nothing else presses upon him. It must be a specific, constant, principal object of study and labor. Remember again that every vegetable substance, and every animal substance, is capable of being converted into a manure.

Now we will look out of the window where we are sitting, and see what in hasty glance comes within our sight, which ought to be saved. There is the garden, with an abundance of weeds and decayed vegetables; collect all them, and let them go into the hogs' pen or the barn cellar. There is the pasture, where bramble bushes, sweet fern, Canada thistles, alder bushes, brakes, &c. abound. Gather them, and you will at the same time clean your pastures. There is the road lined for miles with all sorts of weeds and coarse grasses; get them. There is many a mud hole, which receives the washings of the streets, and where a great deal of valuable and rich manure has been collected; empty that. There is a large shade tree, where the cattle daily collect; and where their droppings are accumulated; collect these and them in the common heap. There is many a rich spot by the side of the roads, which without any prejudice to your neighbor or the public you can plough up; take off the mould, and carry that likewise into your manure yard. There is the refuse of the shoe shop, scraps of leather, &c., collect them and lay them on your land to be ploughed in. There is a clay pit; occasionally get a load or two of that and throw into your barn yard. It will greatly improve the composition. Then you have a wood or grove at hand; collect the leaves from that and lay them in store for littering your cattle-stalls and your sties. But you have a bog meadow; here then is an abundant supply of the materials for enriching your fields. Collect this mud; it is full of the most enriching substances. They may be spread with great advantage upon your grass lands; but they are still better placed upon your compost heap.

We have seen an excellent arrangement on the part of two or three farmers for saving manure, and especially the liquid portions. They daily spread the back part of their cow stables with mould or sand, of which both in winter and summer they keep a sufficient supply at hand under cover; and using this without covering, or covering it with litter, great amount of the most valuable manure is saved.

We have thrown out these hints, not thinking to treat the subject fully, or philosophically; but rather with a view to put other minds to considering what can and what ought to be done. In new countries, where the accumulations of vegetable matter have been gathering for centuries, and have remained on the surface untouched, there is no occasion at present for the use of any manures. The soil is already full and needs rather to be exhausted than replenished. But it is not so with our old soils. We cannot get along without manure. The *geine*, the vegetable pabulum, must be supplied. We have, as Dr. Dana says, the plates, but they require to be filled. We might sit down to a table covered with the richest porcelain or burnished and embossed gold; but if the dishes are empty, we should starve as certainly at such a table as at a naked board. Dr. Dana is likewise of an opinion, in which Professor Hitchcock concurs, that the earthy constituents of the soil are matters of comparatively little moment, provided always of course that they exist in commixture, and are sufficiently retentive of moisture. That is, to recur to the former illustration, it is of little or no comparative importance what the plates are made of, or whether the table at which we sit down be plain deal, oaken, or mahogany; the main point is the food, which is placed upon it. This appears constantly. In our disdained and hard soil, crops are occasionally produced, which vie with any thing which even the fertile alluvions of the west display. One hundred and thirty bushels of corn were raised upon an acre in Plymouth county. Forty bushels of rye, ninety-six bushels of oats, fifty-five bushels of wheat, one thousand bushels of carrots, more than nine hundred bushels of ruta baga, seven hundred bushels of potatoes, and more than four tons of hay have been raised upon an acre even in our own granite soil. The incredulous may sneer at this; that does not at all affect the facts. It neither makes, nor unmakes, nor alters them. They are established by full and incontrovertible evidence. This however has been done by liberal cultivation, liberal manuring, applied with sound judgment; at proper times and in a proper form.

The collection of this manure and its application to the soil and crop is, we admit, laborious, and requires incessant care and diligence. In this respect the new countries have immense advantages over us; and when we compare our severe and expensive cultivation, with their little expense and abundant returns, we are often half disposed to pull up our boots and put on our hat and gloves. But then we come back to the great established position, that agriculture in almost any part of New England having ordinary advantages, where conducted with skill, judgment, and frugality, affords an ample remuneration for all the toil and all the expense incurred; and when we recollect the multiplied social advantages which our community presents over every new country, and take another deep draft of its invigorating mountain breezes, we throw aside our gloves and put on our frock again, and whistle to our team to go ahead.

From the Maine Farmer.

SWINE.

Mr. Holmes:—In no part of the United States can the raising of pork be made a more profitable business than in the state of Maine. In making calculations of the profits of swine husbandry, we should take many subjects into consideration.—First of all, let us notice manure—always acknowledged to be the basis of all good husbandry. I have heard it asserted that many of the farmers of Massachusetts say that the manure a hog will make, when well supplied with materials, will pay all the expense of his keeping. If this supposition is correct, then we can raise pork as cheap as our southern or western brethren, whose swine subsist and fatten or what grows spontaneously.

Every farmer should have his hog pens and his hog yards so modeled that no manure be lost. If the hog yard is upon descending ground, it should be so contrived by digging, that none of its virtues may escape in a liquid state; and if the liquid part of the manure in the hog pen escapes through the floor, it is an unpardonable waste, unless the farmer should cart an abundance of loam and put it beneath the floor of his hog sty, to absorb those rich juices, which are annually lost, if he cannot devise a better method.

Every farmer in the state should be ambitious to obtain the very best breed of swine that can be procured. A poor breed of swine, or in fact any kind of animals, is a dead loss upon the community. Nothing is wanting but a little energy, and a union of efforts, to get rid of all unprofitable stock and substitute in its stead that which will be highly profitable.

It has been said, that in order to raise swine, it is necessary that the farmer should have a large dairy; but I do not think this absolutely necessary. A farmer who has not large quantities of milk to spare for his pigs, may give them other kinds of nutritious food; and probably they may be made to thrive well in a clover pasture, without much other food.

Now let us notice the method of management practised by Arthur Young, esq., of Great Britain, in the management of swine. It is said that in the summer of the year 1766, he pastured 64 swine on only two acres of clover ground. He assures the public that all these swine grew very fast; and also gives it as his opinion, that this use of clover is much more profitable than when converted into hay. Now why cannot a New England Yankee, by practising the same method, realize the same results—even in the state of Maine? Dr. Dean says that it is an excellent piece of husbandry to make a hog pasture of an orchard; and he tells us that an orchard may be prepared with clover as well as any other spot of ground.

I think it is bad husbandry to put apple trees upon good tillage lands. If the farmer has stony ground, that is not easily tilled, there he should plant his orchard. The grass in orchards (especially if the trees be large and stand near each other) is not so sweet and nutritious as that which grows on ground unencumbered with trees; still I think, for many reasons, swine should run in orchards. If the trees in an orchard be too large or too thick to admit of tillage, the little patches between the trees may be ploughed as often as necessary, and sowed with fresh clover seed: to sow a few oats is also a good idea. The farmer need not plough his whole orchard at once but he may plough a part every year,—by so doing he may constantly improve the soil at a very light expense.

If it be admitted that hogs should run in orchards, still I think that every farmer who would raise a considerable number of swine, should set apart at least one acre of land adjoining his orchard, for the purpose of cultivating clover for his swine.

This acre should be kept one half in tillage and the other half in clover, alternately; and as clover is a biennial plant, is best to change from grass to tillage, every second year; thus affording a constant supply of fresh clover. By so doing hogs will not be compelled to feed wholly upon grass growing in orchards. And last, not least, by pasturing land with swine, and sowing clover seed abundantly, the farmer may enrich his soil in an eminent degree.

The winter food for swine should be principally roots, which should be boiled or steam-boiled. This is winter work, and the farmer cannot be more profitably employed. If potatoes are boiled, the water should be immediately drained off. The water in which potatoes are boiled, is of a poisonous nature, and injurious to swine or cattle.

In this state I think it is bad economy to raise much corn or grain for store swine. A warm tight shelter is very necessary for the hog in this cold climate, and this animal, so epicurean and gentlemanly in his diet, must be well lodged, or he will not thrive. An abundance of litter should be furnished him, and this mode of consuming straw is more profitable than when used as fodder for cattle, even if mixed with ruta baga. I would not have it understood that farmers should consume all their straw as litter for swine, but merely that they should not be too stingy in this matter.

I will now say something in regard to the fattening of swine. He that makes the greatest amount of pork at the least expense is the best farmer. Mr. Young undertook a number of experiments to ascertain the cheapest mode of fattening swine, and it is said he gave the preference to boiled carrots.

If good pork can be made by feeding swine with carrots, I think it bad economy to consume much corn or grain for this purpose—at least till we can do away the necessity of "going to New York to mill." But the hog is very fastidious in his diet; he must be gratified with a variety or not thrive, therefore I think some kind of meal should be mixed with his food. Meal made of buckwheat, millet, oats, peas, and barley, are all good: let experiments demonstrate which kinds are best. Swine should be at all times supplied with salt, as well as neat stock. Swine under the process of fattening, should also be furnished with *sauce*, as well as other epicures; such as boiled apples or boiled pumpkins. O! pumpkins,—has any Yankee learned how profitable are boiled pumpkins for fattening swine? To give fattening swine occasionally a quantity of boiled apples or pumpkins will increase their appetites for their other food. One cart-load of pumpkins when boiled is worth two cart-loads of potatoes. How many cart-loads of pumpkins can be raised upon an acre of land properly cultivated and manured? Will farmers try the experiment?

If our farmers are true to their best interests, we can say to our southern and western friends: Whatever else we may want of you—whether it be tobacco, rice or cotton, we will not take your pork.

Rumford, July, 1838. R.

From the Penny Magazine.

NATURAL HISTORY OF THE HERRING, (CLUPEA HARENGUS.)

The herring is found in the third order in Cuvier's arrangement; and with the pilchard, sprat, shad, anchovy, and white-bait, belongs to the Clupeæ genus. It weighs about five ounces and a half. The upper part of the body is blue and green, and the lower parts of a silvery white. Owing to the gill-lids being very loose and opening wide, the herring dies almost the instant it is taken out of the water; hence, perhaps, the saying, "as dead as a herring." In twenty-four hours the gill-covers present an extravasated appearance. The lower jaw is furnished with five or six teeth; the inferior edges of the upper jaw are serrated; and on the tongue there are also small teeth. The food of the herring consists of minute animals which are found in the depths of the ocean; but they will also feed upon the young of their own species, and they may be taken with limpets and also with an artificial fly.

The herring is not found in warm regions, nor farther south than the northern coasts of France. The most interesting point connected with its natural history is the annual movement which it makes. Pennant, whose zoological labors entitle him to much respect, about the middle of the last century gave an account of their periodical migration, which has been implicitly copied by nearly every succeeding writer. He represents them as coming from their great winter rendezvous within the Arctic Circle. "They begin (he says) to appear off the Shetland Isles in April and May. These are only forerunners of the grand shoal which comes in June; and their appearance is marked by certain signs, by the numbers of birds, such as gannets and others, which follow to prey on them; but when the main body approaches, its breadth and depth are such as to alter the very appearance of the ocean. It is divided into distinct columns of five or six miles in length and three or four in breadth, and they drive the water before them with a kind of rippling; sometimes they sink for the space of ten or fifteen minutes, then rise again to the surface, and in bright weather reflect a variety of splendid colors. The first check this army meets in its march southward is from the Shetland Isles, which divide it into two parts. One wing takes to the east, the other to the western shores of Great Britian, and fill every bay and creek with their numbers. Others pass on towards Yarmonth, the great and ancient mart of herring; they then pass through the British Channel, and after that in a manner disappear. Those which take to the west, after offering themselves to the Hebrides, were the great stationary fishery is, proceed towards the north of Ireland, where they meet with a second interruption, and are obliged to make a second division. The one takes to the western side, and is scarce perceived, being soon lost in the immensity of the Atlantic; but the other, which passes into the

Irish sea, rejoices and feeds the inhabitants of most of the coasts that border on it." In a work on subjects of marine natural history, published not more than a year ago, this account is substantially repeated, and it is stated in addition that the different columns are led by herrings of more than ordinary size. Other writers have stated that the annual visitations of the herring are adjusted with the most scrupulous precision to the character of the country along which they pass, and that wherever the soil is meager and the climate severe, there they never fail to resort. This is going much farther than Mr. Pennant, who notices the caprice which the herrings exercise with regard to their haunts. The promulgation of these and similar erroneous notions is productive of mischief in various ways. The belief that a particular part of the coast was invariably haunted by the herrings, excited hopes of commercial prosperity from the fishery, and led to the formation of establishmeuts which it was afterwards found necessary to abandon, owing to the laws which direct the arrival of the fish being so completely fluctuating. Factitious views of the designs of Providence have been taken, which, being founded on error, were liable to be suddenly overthrown; whereas, within the bounds of ascertained facts, there are to be found abundant manifestations of beneficent design, the evidence of which rests upon a more secure foundation. The very uncertainty which characterizes the herrings in the choice of their haunts is attended with advantage, as it occasions attention to be directed to agriculture and to other means of subsistence than that which the ocean supplies, and thus the chances of scarcity are lessened.

So far from the arctic seas being the great resort to which the herrings retire for the winter after having deposited their spawn, it is nearly certain that they are not in the habit of leaving the seas on the shores of which they periodically appear. They leave the shore for the deep sea, and the return of warm weather agains brings them around the coasts. The herring, it may also be stated, is nearly unknown within the polar seas, and has scarcely been observed by the navigators of those regions; nor are they taken by the Greenlanders. A small variety of the herring is sometimes found, and is noticed by Sir John Franklin. The young are found at the mouth of the Thames, and on the coasts of Essex and Kent during the winter. The Dutch at one period carried on the fishery in the deep sea at all seasons. On the western coast of Scotland the fishery has sometimes terminated before that on the eastern coast has commenced. It has sometimes commenced earlier in a southern part of the coast than further north, and on the western coast of the county Cork, before any other part of the United Kingdom. These facts are all adverse to the accounts which have been given of a grand movement in military order from the arctic seas. On the east coast of Scotland the herrings often spawn at a different period from those which resort to the western coast, and at the same time their condition is quite dissimilar. Mr. Jesse, in his "Gleanings in Natural History," states that the herrings of Cardigan Bay are much superior to those taken at Swansea. Dr. Macculloch* is of opinion that this may arise from their obtaining more abundant or different food. He states that in Scotland no migration takes place even between the two coasts, and that when the herrings first appear on the western coast it is not in shoals; and instead of being taken by the net they are taken by the line. Sir Humphry Davy has remarked as follows in his "Salmonia:" "It has always appeared to me, that the two great sources of change of places of animals, was the providing of food for themselves, and resting-places and food for their young. The great supposed migrations of herrings from the poles to the temperate zone, have appeared to me to be only the approach of successive shoals from deep to shallow water, for the purpose of spawning." The presumption, therefore, is that the herring is a permanent inhabitant of our seas, and that there are different varieties of the species. Mr. Yarrell* says:—"There are three species of herrings said to visit the Baltic, and three seasons of roe and spawning. The stromling, or small spring herring, spawns when the ice begins to melt; then a large summer herring; and lastly, towards the middle of September, the autumn herring makes its appearance and deposits its spawn." The same naturalist has discovered what he believes to be a second species of British herring; it is found heavy with roe at the end of January, which it does not deposit till the middle of February. The flavor is milder than that of the common herring, but it is not so large, its length being seven inches, and its depth two.

The frequent changes of their haunts by herrings have been a fruitful source of speculation, though this fact is adverse to the accounts which gave to their migration all the regularity which would seem to belong to so well organized an army. At one time they frequent a particular part of the coast for several years, and they afterwards suddenly abandon it. The change is doubtless occasioned by circumstances which it is their nature to obey. In the time of Charles I, the Long Island, one of the western islands of Scotland, was a favorite resort of the herring, and buildings were erected for the purpose of establishing a fishery, but it was abandoned in consequence of the fish ceasing to frequent that part of the coast. Dr. Macculloch, in his work on the "Highlands and Western Isles of Scotland," has introduced some remarks which are too apt to be omitted in this place. "As vulgar philosophy (he says) is never satisfied unless it can find a cause for everything, this disappearance of the herring has been attributed to the manufacture of kelp. But kelp was not introduced for very many years after the herrings had left the Long Island, as well as many other coasts which they had frequented. It is also a popular belief that naval engagements, or even the firing of guns, cause them to change their haunts. Thus their desertion of Sweden was attributed to the battle of Copenhagen; and now, when guns are at peace, the steamboats are the "sufficient reason." The one reason is as valid as the other. It is a chance if there has been a gun fired in the Western Islands, since the days of Cromwell, and they have shifted their quarters within that period many a time. They have long left Loch Hourn, and Loch Torridon, where steamboats never yet smoked; and since the

* "The Highlands and Western Isles of Scotland," by John Macculloch, M. D., F. R. S.

* "A History of British Fishes," by William Yarrell, F. L. S.

steamboat has chosen to go to Inverary, they have also thought fit to prefer Loch Fyne, to all the western bays. But theories like this have at least the merit of antiquity. Long before the days of gunpowder, the ancient Highlanders thought that the fish deserted those coasts where blood had been shed; so that the gun hypothesis is only an old one revived, with the necessary modifications."

Assuming that the herring approaches our shores from the deep surrounding seas, and does not migrate from the polar seas alone, there are three different circumstances which may occasion its movements: 1. For the purpose of spawning. 2. In pursuit of food. 3. To escape from enemies which prey upon them.

The herring spawns towards the end of October or the beginning of November; and for the purpose of vivification it is necessary that it should be deposited in shallow water, where it may receive the heat of the sun. This instinctive movement is felt in the middle of July, and they are thus brought within the reach of man when they are in the highest perfection. They are worthless as food after having deposited their spawn, and the fishing season of course terminates. Mr. Yarrell is of opinion, from repeated examination, that the herringsile, or young herrings, do not mature any roe during their first year; and hence they are not impelled to retire to the deep sea, but haunt the coasts. The weight of spawn in the herring is 480 grains, and the number of eggs between 3,000 and 4,000. This spawn has been thrown ashore in Orkney, found around the Isle of Man and all along the western shores of Scotland, and in the western lochs. A greater degree of observation would most probably prove that it is deposited around the British coasts generally, particularly the coast of Scotland.

Fishermen have remarked that the herring was most abundant where the medusæ, and other marine animals which give the sea a luminous appearance, were to be found. The movements of herrings are doubtless frequently determined by the time and place where food is abundant. If it is not to be found in one spot it must be sought for in another; and the apparent caprice which they show in frequenting places at irregular times and irregular intervals, is determined by a provident regard to the abundance of food with which those places are supplied.

Lastly, in endeavoring to escape from whales, grampuses, sharks, and other enemies, the movements of the herring are the result of necessity; and nothing seems more unlikely than that they should, under such circumstances, display an instinctive attachment to particular places.

DESULTORY REMARKS ON THE SILK CULTURE OF THE UNITED STATES.

It has now been several years since sundry companies were chartered, in the northern states, with large capitals, (nominal or real,) for the purpose of prosecuting the culture and manufacture of silk. Many more such companies have since been formed, and have commenced operations; and, latterly, some have been established even in the lethargic south, and in the climate by far more proper and suitable for this business than that enjoyed by our industrious northern countrymen. The operations of these large joint-stock corporations are in addition to those of hundreds of individual adventurers, who have commenced, on their separate account, what is called the "silk-business." The first object of all efforts to cultivate silk, is, necessarily, to raise mulberry trees, to furnish food for the worms; and the kind planted has been principally the Chinese mulberry, or *morus multicaulis*. The facility of propagating this variety, by cuttings, is so great, its growth so rapid, the annual multiplication of plants so enormous, and the maturity of each (to the point of supposed fitness for feeding,) so early, that two years' time would suffice to raise a very large supply, from a commencement with a few hundred young trees; and, in three years, the number might be made equal to almost any demand of a single silk establishment, of no older standing. There are also powerful incentives to use these facilities, in the liberal legislative bounties offered for the production of silk, by at least six of the northern and middle states. In Maine, the bounties paid from the treasury for this object, are 5 cents a pound upon all cocoons grown, and 50 cents on each pound of silk reeled. In Vermont, a bounty of 10 cents is offered for every pound of cocoons. In Massachusetts, $2 the pound is paid, as bounty, on all silk grown, reeled, and "throwed" in the state, "which bounty alone is considered by silk-growers to be sufficient to defray all expenses attending its growing, reeling and throwing." (Mr. Adams' Report to Congress. See Far. Reg. Vol. V, p. 65,). In Connecticut, (where silk has been grown 50 or 60 years, without legislative fostering,) the treasury pays a bounty of $1 on every 100 Italian or Chinese mulberry trees of five years old, and 50 cents a pound on all silk reeled on an improved reel. All these bounties were in operation as early as 1836. We do not know the rate of bounty paid by Pennsylvania and New Jersey; but they are so high, (as stated in a previous selected article on page 355 of this Vol.) as to "have been found sufficient to pay all the expense of producing the cocoons and reeling the silk, making the whole produce clear profit."

With such facilities and such inducements for the production of silk, it is very remarkable that so little has yet been accomplished, by all, or by any, of the numerous companies and individuals who have undertaken the business. Wonderful reports are made, and published with great parade in the newspapers, of the prospects, and intended operations of almost every newly established silk company; but little, if any thing, is afterwards heard of what they have actually produced. It is not to be supposed that reports of successful operations would not be published if there were sufficient grounds on which to place them; and therefore, though the testimony is negative, it is still satisfactory to establish our inference, that but little has yet been done in producing silk; and that silk-culture on a large scale, and as a profitable branch of agriculture, is yet to be commenced in this country. Judging from the various prefatory reports of silk companies, and deceived by their confident tone, we had formed a very different opinion; and by republishing their reports in this journal, we may have, unintentionally, helped to delude the public. If the adventurers in silk-culture in the northern states have really done much in producing silk, the facts have not been made public, in any way comparable to the industry used to extend the publicity of their first expectations and intentions.

The only certain and direct evidence of the very small amount of silk yet produced, which has reached us, is in the "Statistical Tables" formed and published by order of the government of Massachusetts. From this work it appears that all the silk factories of Massachusetts (four in number,) in the year ending April 1, 1837, employed 125 hands, and produced of manufactured goods, the value of $56,150. This does not show how much raw silk was produced; but the probability is, that these factories worked up all the silk made in Massachusetts, as the larger portion of their raw material was certainly of foreign growth.

A gentleman of Virginia, who was desirous of going into the silk culture, and has since done so, last year visited the principal silk establishments in the northern states, for the purpose of gaining information as to their operations and the results. He told us that the greatest annual product of raw silk which he could hear of, at any one establishment, amounted to no more than 40 pounds. It was true that at some of them, silk manufactures were carried on; and they had been at others, which had suspended or stopped manufacturing, on account of pecuniary difficulties; but the materials for these manufactures were mostly imported from foreign countries.

The only inference which we can draw from the information before us, and the testimony above referred to, positive and negative, is, that most of the adventurers in the silk business (so called,) have considered the making of silk as a secondary, ulterior, and perhaps contingent object, and have been laboring and speculating in the culture of mulberry plants, not to feed silk-worms, but to sell to newer adventurers; and the vast profits to be derived from the making of silk, were held up to the public principally to produce greater eagerness to purchase the plants and cuttings of Chinese and other varieties of the mulberry, at the enormous and extortionate prices at which they have been sold. The article at page 355, headed "*Morus Multicaulis*" is a capital specimen of these stimulating reports. This may be a *bona fide* and disinterested statement; but certainly it has every appearance of a salesman's indirect puff—such as are at least half the publications on this subject which have appeared. There is no advertisement so effective as that which appears in the false guise of editorial approval and recommendation.

But without the advance of prices, which this writer anticipates, for plants of the *multicaulis*, those heretofore obtained are sufficiently high to make it far more profitable to sell the plants, than to keep them to feed silk-worms on, or than to pursue any other branch of agricultural industry. From every single cutting of one bud, (allowing for all necessary risk of loss and failure,) may be raised, in one year, a plant of four feet or more in height; and such plants, (of one year's growth) divested of all the side branches, have been sold regularly and readily at $25 per hundred; and the twigs, trimmed off, at $2 per hundred buds—and a single plant will sometimes produce a hundred such buds. An acre of rich land will bring more than 10,000 plants, and the crop is completed and ready for market in one season. By cutting off the whole tops, at the ground, (so as to take away every bud,) each root will, in the second summer, produce three or four times as many buds as in the first year's growth, to be again cut off and sold. Were there ever greater profits offered? And is it not perfectly natural and reasonable that these profits should be preferred to those offered by silk-culture proper, even though doubled by legislative bounties?

Thus the true, and, as we fully believe, the great profits which may be realized by rearing silk, have been lost sight of, and disregarded, to reap the greater though transitory profits of selling mulberry plants. And the combined action of the cunning salesmen and puffers, and the strong disposition of the public to be duped and cheated by every professional humbugger, has produced a *multicaulis mania*, that promises to equal any of its fore-runners in the annals of speculation and delusion. Enormous profits have thus already been made by northern nursery-men, and much of them from southern purchasers. And we are sorry to learn that the same spirit is spreading rapidly in Virginia; and that many persons are now beginning what is called the "silk-business"—but which is merely raising mulberry plants and cuttings to sell. And a profitable business this may be, to early adventurers; though a bad one for all the later ones, who do not design to put their mulberry trees to their legitimate use of feeding silkworms. It is plain enough, that even if millions of dollars should be received for plants that are not used, first or last, for any purpose except to be sold, that there will be no gain to the community; and a total loss to the buyers and producers who cannot sell. It is thus that truly valuable products, and a profitable branch of agricultural industry if properly pursued, may be converted into a humbug, and become one of the many modes of producing deception and loss to dupes, and profit to the dupe-makers.

What adds to the strangeness of the slow advance of the product of silk in the north, is the fact that there existed, for several years, two periodical journals, published at a low price, and circulated very extensively, which were devoted exclusively to giving information on, and encouraging the extension of silk culture. These were the 'Silk-Culturist' of Hartford, and the 'Silk-Worm' of Albany. Another such publication has recently been started in another state. Here is a most prodigious and imposing array of means; and the end, or result, is in comparison ludicrously small, even though it may exceed ten-fold the amount of that of which we have yet been informed.

There has been another new branch of agricultural industry proposed in this country, and (if we were to judge from printed reports,) it might be said was commenced, more than eighteen months ago. This is the making of sugar from beet-roots. The reported profits of this business in France caused a very general desire to introduce it in the northern and middle states. The statements published (many of which are to be seen in our pages,) seemed to promise sufficient remuneration to the undertakers. In addition, the legislature of Massachusetts, in the beginning of 1837, offered a bounty of three cents a pound on all sugar made in that state from beet-root, (see Farmers' Register Vol. V, page 47.) There was then growing a strong beet-root fever, which has continued since, and we have no direct testimony of its abatement at this time. But neither have we yet heard of any practical results, or profits from the business—nor indeed whether any thing has been done in it, except (according to usage,) to form joint-stock companies for carrying on the culture and manufacture. Strangely enough, since schemes of beet-root culture have been in vogue, they have been regularly connected with the schemes of silk-culture. Yet, what the two things have to do with each other, is more than we can conceive—or what they have in common, except the quality of being converted into humbugs. The joint-stock companies latterly formed for silk-culture, or proposed and announced in the newspapers, have very generally added the making of beet-root sugar to their objects, and the title of the association. This incongruous yet very general connexion has been even carried into the proceedings of the congress of the United States; and a long and detailed report has been sent forth from the Committee of Agriculture, on the cultivation of the "Mulberry and Sugar-Beet," in a pamphlet of 51 octavo pages; of which many thousands have been printed and circulated, to add to the profit of the government printer, and to help the nursery-men, whose letters are there published, to sell their mulberry plants. With so much encouragement, direct and indirect, by both state and federal government, it is truly surprising that both the silk-culture and beet-sugar-manufacture should be still unable to give evidence of life, or to make any figure, except in reports of the formation of joint-stock companies, and their intended operations.

It will, perhaps, be inferred, though very erroneously, from the general tenor of the foregoing remarks, that we have no faith in the profit of producing silk in this country, nor in the legitimate profit of rearing the Chinese mulberry as means for that end. Not so, as to either opinion. Still, because of our endeavoring to expose the delusion, and repress the misdirected zeal, and speculating spirit, which have been built upon the true and solid claims of this business to approbation, we expect nothing more than to be considered as opposing, throughout, the culture of silk as altogether unprofitable, and the Chinese mulberry as worthless; and its being raised by any one as an evidence of his being either a knave, or a dupe of knaves. It seems that moderate, qualified, and discriminating approbation of agricultural opinions and practices, is no more tolerated, by most persons, than similarly limited approval of the political men and measures that they sustain. Every man is required, whether on agricultural or political subjects, to "go the whole hog," and to approve or condemn, as entirely as does a blind or bought political partizan. Qualified and limited approval, is considered as but "damning with faint praise" We therefore do not expect to leave the impression on readers in general, that we are friendly to, and strongly in favor of, the commencement and extension of silk culture. This expected misapprehension cannot be entirely guarded against, and we shall not take much trouble to avoid it, or lessen its influence. We will merely state, that we have no private interest whatever in discouraging silk-culture; and that we have some small private interest the opposite way, inasmuch as we are preparing to come into the market with *multicaulis* trees and cuttings, as soon as we can furnish them at one-fourth of the present prices.

We certainly doubt the fitness of the climate of the northern states for profitable silk-culture; and more than doubt the fitness of that cold and inhospitable region for so tender a plant as the *morus multicaulis*. But we fully believe in the suitableness of the slave-holding states for both; and we are confident that fair trials will show very profitable results. And if the doubts and disbelief just expressed, are indeed unfounded and unsound, and New England is, in truth, well adapted for silk-culture, then, *a fortiori*, so much the more profitable must it be in Virginia, because of our warmer and longer summers. We have also other advantages (which we have several times before urged) in our far cheaper land, and cheaper slave-labor. Many slaves could be producers who now are merely consumers. We are now, as heretofore, and as also frequently expressed, anxious that the business of raising silk shall be properly commenced and pursued in Virginia; yet we have but little favor for, or confidence in, the new-born zeal for raising mulberry plants merely to sell at great profit, to other persons, who will buy them with precisely the same object. It is but a new type of that spirit which showed itself in the Merino sheep mania, which formerly prevailed, and in the far more injurious race-horse-breeding mania, which is now at an unprecedented height in Virginia.

The *morus multicaulis* is undoubtedly a most choice variety, and it offers greatly increased facilities to the young silk-culturist. Whoever is desirous of commencing the silk business, and is without mulberry trees, or enough of them, ought certainly to plant this kind in preference; because from its ease of propagation, and rapid growth, it can more speedily supply enough food for the worms. Moreover, from the larger size of the leaves, they are gathered with much less labor; and from their superior nutritive quality, a less weight will serve to feed a given number of worms. It is also *said* to produce the finest and best silk. This may be so; but it is far from being satisfactorily established. And even if so, a countervailing objection, held by some in France, is, that the fibres are weaker than silk produced from other kinds of mulberry leaves. But neither this nor any other foreign kind is indispensable. If the new beginner has enough of the native mulberry, (*morus rubra*,) though it has been pronounced, and generally admitted, to be worthless, compared to the white, and Chinese, we would advise him to proceed to raise and feed the worms, without waiting for the growth of any other kind. This kind of food is perhaps equal to any, and will be at least quite good enough for the other parts of his early management; and, in the mean time, by planting a few thousand cuttings of the *multicaulis*, of a single bud each, with careful culture, any desirable number may be raised in as few years as will be necessary for the adventurer to learn how to manage his worms, and their products. We would further urge on every farmer who has the least idea of hereafter trying the business, to plant a a few of these trees as a stock to propagate from, if needed. But we also ask him not to believe that this, or any other particular kind, (as either Brussa, Canton, &c.) is so far superior to others as to be indispensable; and we advise him not to buy them, or at least but very few of them, at the exorbitant prices which the always easily gulled public have heretofore paid, and which are now threatened to be advanced.

The northern nursery-men have as yet had the supplying of the southern demand for these plants, although at double the prices at which far better plants might have been bought in Virginia. John Carter, near Richmond, who went early (too early, as it seemed,) into this business, for want of purchasers, had to dig up and throw away thousands of young *morus multicaulis* trees, after they had grown so large that he could not spare them the ground they occupied. Subsequently, he sold the remnant to a great northern nursery-man, at less than half the price at which these (or much worse ones, if not these,) were sent back from New York, and sold in Virginia, and in some cases probably to gentlemen not far from Richmond, but who had not heard of any supply to be obtained except from northern nurseries. The farther north the plants are raised, and the more careful and more forcing their culture, the worse they are to propagate from. The northern nursery-men endeavor to remedy the defect of their climate by using the richest soil, and the most stimulating culture. The plants are pushed in growth unnaturally; and when winter stops their further vegetation, half the year's increase of wood is immature, and is so succulent and tender as to be unable to stand the winter, and unfit to raise from, even if kept through winter sheltered from frost. These immature buds, however, *will sell*; and they are fit for nothing else. A southern plant, raised without forcing culture, is worth more, to propagate from, than half a dozen from a northern nursery, of equal size. This has already been fully proved in Virginia, by those who have bought plants and cuttings from the north, as well as near home, and subjected both to the like treatment after being planted.

It was said above that in France an opinion was held that the silk produced from feeding on the *multicaulis* wanted strength. This is not the only objection there made to this kind of mulberry. It is considered to be short-lived, and that its decline and decay is as much in advance of other kinds, as its early growth and fitness for use. If this be true, it has not been suffered to be discovered, much less reported, in this country; because almost every possessor of the trees has regularly cut them up every year into cuttings to produce young plants, and very few have been permitted to grow even to be five years old. Now whether they would begin to decline so soon as is alleged, or not, if permitted to live, it is certain that few persons in this country have ever seen a plant except under three years old, and of course in a state of greater succulence and more rapid growth than to be expected in after time. This remark would apply to every kind of tree —and in a remarkable degree to the native mulberry, of which the leaves in early growth (even in the forests) are often seen four times as large as is usual on large trees. But all the interested puffers and salesmen of the *morus multicaulis* assume, and their customers seem as readily to admit, that the succulent and large-sized leaves, so remarkable in the early and *forced* growth of the trees of one and two years, are always to distinguish the mature tree. This expectation must be unfounded, judging by all analogous cases; and moreover it is very doubtful whether this feature would be desirable, even if it could be retained. The large size of leaf, so far as caused by, and indicative of, succulence in the plant, and that again caused by excessive supplies of nourishment to the plant, is certainly not desirable for its proper and sole object, that of producing silk. For it has long been known in the silk-growing parts of Europe that the leaves of mulberry trees growing on moist or very rich land, and therefore of rapid and succulent growth, are not as healthy food, and do not furnish as good silk, nor as much profit in the product, as the leaves of trees on poor and on dry land. Thence it may be safely inferred, that if the forced growth of the *multicaulis* in this country had been used to much extent to feed silkworms, instead of to sell to new adventurers, it would have been found to be liable to the objection just stated. But that objection would probably not have been promulgated, as being likely to lessen the greatest value of this kind, which is to be sold at high prices.

The first introduction of this plant from the Philippine Islands, was into France; and its superior advantages in some respects were there seen and generally made known, so as to insure to its culture a favorable consideration, and a fair trial. But though introduced in this country, from France, after it had excited attention and gained much favor in that country, the propagation has spread here so much more rapidly, that there are already ten times the number of plants here that there are in France. The cause of this remarkable difference is plainly enough seen in the different circumstances of the culture in the two countries. In France, the main object in cultivating this tree, was to feed silk-worms. Here, the almost *sole* object, has been to sell the plants, and buds, and to produce as much growth as possible for each year's harvest and sale. Besides, each culturist in France would scrutinize (perhaps too severely) the characters of the new mulberry; while here the interest of the culturists would necessarily direct the concealment of all defects, and the exaggeration of the real advantages. In this way the northern nursery-men have duped their neighbors more to their injury than their southern purchasers; for the plants *will* flourish here, and they *will not* stand the winters of New England, notwithstanding all the strong assertions of the producers to the contrary. Whatever may be the true and superior advantages of this tree, they will principally redound to the benefit of the southern states.

After the foregoing portion of these remarks was in type, we had opportunities of being better informed on two of the points mentioned above; one of which was doubtful, and the other mistaken, because not tested by observation and experience of sufficient duration. These are, the objections, made in France, to the alleged very early decline of vigor and death of the *morus multicaulis*; and the supposed lessened size of the leaves of trees of matured growth. On the side of F street, Shockoe Hill, Richmond, we have just seen trees of this kind, of which the largest are more than four inches through the body, although, judging by the eye, they are not more than 18 feet high. These were not permitted to grow *many-stalked*, as the name implies, and their nature requires; but being designed for ornament, had been trimmed, and forced to grow *single-stalked*. Though growing well and luxuriantly, and having no certain indications of the use of the knife, the want of height proportioned to the trunk seemed to show that the tops of these trees had been cut down at an early period of their growth. Another tree, in the garden of D. I. Burr, deceased, though not more than 2 to 2½ inches through the body, (this also having been trimmed to a single stem,) stands 22 feet high, as measured by our eye; and it would be 24, or more, if the upper branches were not borne down by the weight of their burden of leaves. The ages of none of these could be then learned; but the oldest are probably fully eight years old; and all appeared as thriving, and as much in a growing state as any other trees of like age, and of kinds that may live for half a century or more. The leaves, also, (to our surprise, and conviction of having made an erroneous anticipation,) were but little if any smaller than the usual size of those on younger trees. These facts alone would serve to remove the fear of a very early decay of vigor, and decline and death of the tree; and decide that the size of leaf does not diminish in the older tree, and on better matured wood, in proportion to that change in the common mulberry, and many other trees.

In addition to our own personal observation, we have just received the following better testimony from G. B. Smith, esq. of Baltimore, in answer to inquiries on these two doubtful points. "My old tree," says Mr. Smith, "was one year old when I got it, in the spring of 1828; and is now, of course, eleven years old. It has been transplanted several times; and the last time when it was eight years old. Of course, it furnishes no criterion of the state of the tree at this age. Several large stalks of mine have perished; and there are now 6 stalks, from 6 to 15 feet high. It has also been every year deprived of its branches, and sometimes of its top-wood, for cuttings. Many of its leaves now measure 15 inches in length, by 13 to 14 inches wide. Its leaves are as large now as ever they were."—"The *morus multicaulis* is a *many-stalk* tree; it is constantly sending up shoots from the crown of the roots, like the filbert and lilac; and, consequently, the older stalks die out; but whether from natural decay, or from being perished by their numerous younger brethren, I do not pretend to say. But that the tree will live eleven years, under very adverse circumstances, I know, from the fact that I now have a tree of that age. All many-stalked trees throw off their old wood occasionally, to make room for the young and more vigorous. But how this fact can be any detriment to the *morus multicaulis*, I cannot comprehend, as the roots send up half a dozen stalks, generally, for every one that decays."

This additional testimony and correction of previous error and doubt, we insert, not only readily but, gladly; for no one will receive with more welcome, or publish with more pleasure, any new, or confirmatory evidence of the valuable qualities of this tree, as offering peculiar facilities and aid to silk-culture.

From the Penny Magazine.

THE AMERICAN MANNER OF MOVING HOUSES.

In England we consider it no trifling affair to remove our household establishments, when circumstances render it necessary for us to do so; whereas our trans-atlantic brethren, the Americans, set about removing their houses (goods and chattels included,) without considering it matter of difficulty or hardship. To be sure, their buildings (I do not include those of their older towns and cities) are less substantial and solid than ours; for a frame of moderate-sized posts and scantlings, lined within and without with thin pine boards, is not quite so ponderous an affair as a building where the walls are of massive stone, nor even as one of bricks and mortar.

Before I proceed to explain the usual plan adopted for removing buildings, I will relate some circumstances connected with a frame building with which I was acquainted, and which constituted a fraction of the capital of the county in which I resided. While the town was but in its infancy, an acquaintance of mine built a "store," (shop for general merchandise, with granaries, &c., overhead,) in which he commenced the business of a general merchant. In a few years the population increased, and the town became much enlarged; and so did the business of my acquaintance, inasmuch that he found, or fancied, his original store too small for him. In this dilemma what was to be done? The difficulty was soon solved; he sold his store, to be taken off the premises, for he wanted the ground to build a larger one upon. A dress-maker was the purchaser, who removed it about eighty yards along the same street, and had it fitted up to suit her line of business; at the same time converting a portion of it into apartments to dwell in. How long she occupied it I do not precisely recollect; but, quitting that part of the country for a few years, when I returned and looked for my old acquaintance, the milliner's store, nothing like it was to be seen. I repaired to the original owner, and inquired if some calamity had befallen it, or if it were still on the move? "I guess," replied he, "that you will find it in Centre Avenue, a little below the Washington Hotel. It is now the property of

Mr. D—, my old clerk, who has converted it into a 'grocery.'" And, to be sure, there it was! and one of the greatest nuisances of the place; for Mr. D—'s grocery was the rendezvous of all the lazy, drunken vagabonds connected with the town and neighborhood. I do not remember how many years it continued the resort of the dissolute; but it was after the temperance societies had made some progress in that part of the country, that happening one day to be in the town, I observed more bustle than ordinary in the vicinity of Mr. D—'s grocery, and upon inquiring what was going on, I learned that the grocery was once more on the move; that it had been purchased by a stanch temperance man, a boot and shoemaker; and that he was removing it into the vicinity of his own dwelling-house; not only into another street, but to a distant part of it; and there I left it when I removed from that district some years afterwards—one part of it occupied by half a dozen cobblers' stalls, and the other part a well-supplied shoe and leather store.

I was once present at the removing of a large grist-mill, containing four pair of mill-stones, besides all the machinery and apparatus necessary for the purpose of carrying on the manufacture of flour for exportation. It was a stout frame-building, of the dimensions of fifty feet by forty, and four stories high. After it had been some time in operation, it was ascertained that in dry seasons the situation did not command a sufficient head of water; but as the stream had a considerable fall, it was obvious that if the mill were placed 100 yards further down, the desired fall would be obtained. To effect this the owner of the mill agreed with an old Yankee to remove it, just as it stood, to its new site, for the sum of one hundred dollars (a little over £20 sterling,) a small sum apparently for such an undertaking; for if the building or machinery sustained any damage, the person undertaking the removal was to make it good. Large frame-buildings, like the one in question, require stout timbers for their posts and beams; the principal timbers in this mill were from twelve to fifteen inches square. Besides the four bottom beams or sills which rested on the stone foundation, there were three others of a similar size mortised into the end ones, and equidistant from each other; so that there were, in fact, five transverse beams on which the lowest floor rested. The first thing to be done was the laying down of wooden ways, upon which the building was to travel upon rollers; to accomplish which, five rails of squared timber, at distances asunder exactly corresponding with the foundation-timbers of the mill, were properly placed and secured, in lines extending to where a new foundation of stone had been already prepared. After this the building was raised perpendicularly, by the means of wedges of hard timber, about eight inches, in order that eight-inch wooden rollers might be placed under the several lower beams and sills; which having been done the wedges were withdrawn, and the building then rested upon the rollers. The rollers were made of hard timber, each about five feet long, and perforated near each end with suitable holes, for the reception of hand-spikes or levers, to be used by the persons employed in the removal of the building. Under each beam were placed four rollers, so that under the whole five beams, twenty were employed. I should have remarked that it was necessary to remove the bottom floor-planking, in order that the persons employed at the rollers placed under the middle or inner beams might be enabled to work them. Two persons were appointed to each roller, one to each end; and every thing having been properly fixed, and all the forty men at their respective posts, the old Yankee captain gave the word "move," when the fabric instantly began to advance on its wooden ways. As soon as the rearmost rollers were set at liberty in the rear of the advancing building, they were straightway carried forward and placed under the extreme forepart of the beams they severally belonged to. It was found that the power of the forty men stationed at the rollers with their handspikes or levers, was amply sufficient to keep the building in motion without any extraordinary exertion being called for; and as there intervened no obstacle in the distance the mill had to travel, in about three hours it had advanced to its destined resting-place. Having safely arrived there, wedges were again employed in order to free the rollers, and to settle it gradually on its new foundation. The whole undertaking was completed without the slightest injury occurring to any part of the building or machinery; not a square of glass was broken or cracked in any of the score of windows that belonged to the various parts of it; not a pin or a nail was sprung or broken.

From the American Farmer.

HYDROPHOBIA IN SHEEP.

Springdale, Va. 18th March, 1823.

Dear Sir,

The effects of hydrophobia were singularly exhibited a few years since, on a flock of sheep belonging to the plantation of my father, in this county. As the facts were at the time perfectly novel to me, and may still be interesting to others, I have thought them not wholly unworthy of a place in your excellent paper.

In the month of February, 1810, while it was intensely cold, and a very deep snow covered the ground, the flock of sheep were confined in a small enclosure surrounding a fodder house, which served the double purpose of supplying them with food and protecting them from the inclemency of the weather. In this situation they were visited by a dog belonging to one of my neighbors, which, although there had been something rather extraordinary in his appearance and conduct, had evinced no very marked symptoms of hydrophobia. About day-light in the morning he was discovered by the negroes, in pursuit of the sheep in their inclosure; but on seeing them, and being menaced with a stick, he ran off; but instead of going immediately home he took the direction to a neighboring village, where he bit two cows, and disclosed other marks of unusual ferocity and ill-nature. These circumstances at length excited suspicion of the true nature of his malady, and on his return home, he was shot. Upon examining the sheep, it was found that 15 or 20 had been bitten, most of them so slightly, that in one instance, only, was it thought that death would probably ensue, merely from the wounds. The peculiar manner in which the animals were bitten, and the number injured, showed that the dog was actuated more by a strange and malignant propensity to mischief, than from the mere desire of food. Instead of killing them immediately, he appeared to have attacked them merely for the purpose of teasing them; and the impressions of his teeth were barely visible, on their ears and faces, and not unfrequently on their legs. In every case, however, he succeeded in bringing blood; most of the female sheep were in their last stage of pregnancy, and so trifling was the injury they sustained, that they bore their lambs as usual, without exception; and before the lapse of a fortnight, their wounds were entirely healed. About this period hydrophobia first made its appearance. Two of the flock were found sick, and unable to stand, before they were known to be affected. In a few days the disease was observed in several others, and in this manner three or four in each week, disclosed the symptoms, and six weeks had elapsed before the whole number bitten had been affected.

There was a peculiarity attending the early symptoms, which soon marked the individual destined shortly to become a victim to the dreadful malady. It first attracted attention by pursuing and tormenting its associates, by almost incessant libidinous actions. The diseased were all females, and several with lambs at their sides; yet their venereal inclinations were so powerful, that they exhibited in a most astonishing degree, the manners and actions of the other sex. In this manner did some of them, with persevering industry, tease and torment a companion, for twenty or thirty minutes, until the fugitive would find shelter by mingling with the flock—a second would then be attacked in the same manner, and have to run the same vexatious round; sometimes the fugitive would turn upon its pursuer, and by an effectual resistance obtain relief. This paroxysm would intermit occasionally, and the infected sheep, would feed peaceably with the others, if not disturbed; but upon approaching the flock, it could readily be recognized by its bold countenance, staring or glassy eyes, and an advance to make battle. In this state of the disease they would attack a man with much resolution, and beat him with their heads. In some instances I recollect seeing them advance from fifty to one hundred yards, from the flock, and attack persons so furiously, that they were obliged to defend themselves with sticks. After discovering more than common strength and vigor for a short time, an instantaneous debility appeared to come on, and their limbs refused to do their office. I have seen them, in the very act of advancing vigorously to battle, fall as suddenly, as if shot by a ball from a gun. In a few minutes their strength would return, and they would rise again to renew the combat. This I think might generally have been considered the second stage of the disease; yet in this situation their amorous propensities continued, for I have seen them fall, while pursuing other sheep of the flock. These paroxysms, or falling fits, at last became more and more frequent—the animal refused to take food, and became too feeble to follow the flock. But even in this state of excessive debility, and while apparently suffering the most excruciating pain, the inclinations which predominated throughout the disease would still manifest themselves, until a complete exhaustion would terminate the struggle. The lambs which had continued to suck during the lives of their dams, were now fed by hand, and if I recollect aright were without an exception raised. The wool was invariably saved after the death of the sheep, without any inconvenience whatever; indeed, as a proof that the blood of the infected animal cannot be injurious, unless commingled with that flowing in the veins of the living; the skins were taken from several hogs, which died of hydrophobia, the same time, and the bodies frequently eaten by the others, with entire impunity. It was a remarkable circumstance, that with the infected animals, putrefaction ensued almost immediately after death.

Very respectfully,

WILLIAM M. BARTON.

For the Farmers' Register.

WOLVES IN FAUQUIER.

Fauquier Springs, Aug. 22, 1838.

While viewing, from an eminence at the extremity of Warrenton, the extensive and beautiful prospect of fertile valley and mountain lands stretching to the Blue Ridge, Mr. ——— directed my attention to the Leathercoat mountain, which is in full view, about eight miles distant in a direct line. There was, near to, but below its summit, the appearance of a line of white huts, or some other kind of artificial structures of humble size, spread over a considerable extent of ground. He explained, however, that they were naked rocks—of which it is rare to see much of any of the mountain sides in Virginia composed, and still more rare of the fertile South-West Mountains, to which range this one belongs. I was much surprised to learn, that among these rocks, and in the dens which they formed, there were wolves still sheltered, which had been residents of the Leathercoat, and the adjoining Bull-run mountain, for the four last years. No wolves had been heard of before, during the lives of any of the present inhabitants of Fauquier, nearer than the rarely visited and scarcely accessible rocky cliffs and precipices of the Alleghany mountains, perhaps one hundred miles distant; and it is a strange and unaccountable circumstance, that this colony should have been settled so recently, so far to the eastward. The stealthy and hidden manner of their emigration is as remarkable, as the motive for it is inscrutable. The hungry band of prowlers must have passed over, in their journey, a very wide extent of fertile valleys, filled with flocks and herds, and also of higher mountains, furnishing as good places for concealment, before reaching their chosen fastness and abode, from which they have not since been driven. For a long time the actual presence of these cunning and ferocious depredators was not suspected by the people of the neighborhood, though they were killing their sheep by hundreds. The losses were ascribed to dogs; though such extensive and long-continued destruction, without discovery of the particular actors, had never been heard of previously. Before the midnight and bloody forays of the wolves were effectually checked, they had been extended as far as twenty miles from their mountain strong-hold; and they had killed, in all, more than 1000 sheep in this county. As soon, however, as the nature and the abode of the enemy were known, large hunting parties of hundreds of the neighbors, with guns and with all their dogs, scoured the mountain and its places of concealment. They formed a circle around the mountain, as practised in Europe in ancient times, for the sport of royal huntsmen; and gradually closed their ranks, and lessened the surrounded space, by advancing slowly and regularly up toward the central point of the mountain, and driving the roused and encircled wolves before them. Besides the rocks, and the usual difficult ground of steep and rocky mountain sides, there is much of the mountain covered with that strong and large evergreen shrub, or small tree, the laurel, improperly called the ivy-bush, which spreads in many cases over acres of the land together, and forming, as it always does, the most dense and impenetrable thicket. The stoutest dogs, and in numbers, were scarcely able to cope with their new and fierce enemies; and many, in attacking them, perished by the long and sharp fangs of the wolves, when driven to desperate bay. When the wolves could be seen and reached, these conflicts were usually speedily ended, by the rifles of the hunters. In different hunts of this kind, 24 wolves were killed, without all being destroyed, or the diminished remnant being induced to abandon their chosen place of refuge. However, being intimidated by the attacks on them, and their heavy losses, they have made no incursions into the neighboring farms, and committed no known depredations on the flocks, for the last two years. But some still retain their position, in spite of all the force and craft of the hunters. as resolutely and as obstinately as the Seminole Indians have done against the arms and diplomacy of General Jesup. A sufficient evidence of the still-continued presence of the wolves in these mountains, is, that a man has during this year found and killed, in their dens, eight wolf-whelps. E. R.

From the Quarterly Journal of Agriculture.

PRACTICAL EFFECTS OF DRAINING.

The system of draining introduced into Scotland some years ago, and proceeding so rapidly, must be regarded as the greatest improvement of modern times. The landlord and farmer do it jointly. Here is a safe investment for money—the expense repaid in twenty years, regular interest, and the land improved in value above one-third. Green crops are grown in great abundance after draining, where no attempt could be made before, and the farmers allow they have four crops in three years, and the draining pays on an average eight per cent. I know an instance of a wet clay soil, almost covered with rushes, being drained and improved at an expense of £15 an acre, ($65); the green crops were so productive as to repay the expense in one year, and after deducting the old rent, the improvement pays fourteen per cent. upon the outlay. The drains are from 20 to 30 inches deep, and at the distance of from 12 to 20 feet, sometimes in the furrows of the field, or across, or obliquely, as the descent may suit, and sometimes the land is laid flat. Draining, to be remunerative, must be done effectually. A field cannot be drained by putting a drain in a corner, one here and another there; by running one across the field, and another diagonally to that. It must be done completely, or not at all, for half measures are useless.

From the Franklin Farmer.

SELECTION OF SEED WHEAT.

Richmond, Ky., Aug. 6, 1838.

Many years ago, a farmer in this quarter, who cultivated the same variety of wheat and in the same manner as did his neighbors, was known to have a yield of a third more to the acre. Upon inquiry as to the cause, the unsatisfactory answer was given—"I sow barrel seed." The neighbors purchased of him their seed wheat, and the first year had a yield equal to his; but selecting their seed as formerly, the second and third crops were but little, if any better, than was raised by them previous to their purchase of seed. They again purchased, and their fourth crop was equal to the first, but their fifth and sixth crops were like their second and third. How to solve this apparent mystery, caused many a neighborhood consultation and discussion. The vender of the seed saw too inviting a prospect to make money from the sale of seed wheat to induce him to disclose the manner of its preparation, and he struggled to keep it concealed. It was ultimately discovered, however, and was as follows:

When you are ready to get out your wheat, place a barrel or box in your stack-yard, open at one end; before you pass the bundle to the treading floor, give it one or two strokes across the open end of the barrel or box, by which the best matured grains will shatter off; then winnow and use for seed.

Thus selected, it will be far superior to the seed prepared by running it through a coarse sieve; for it is known to every observant farmer, that many of the largest grains of both wheat and rye are unripe or diseased, and yet they do not shatter out as easily as those which are perfectly ripe.

W. C. G.

From the New England Farmer.

CURING CLOVER HAY.

There prevails with many farmers a strong prejudice against clover hay; and indeed in the condition in which it usually is found it is a very coarse miserable fodder, and hardly better than so much brush. Our northern clover sown on richly-manured land, and with the small quantity of seed commonly applied, makes a rough product; and, as the flowers and seeds are generally shaken off in the making, it contains little nutriment, and is scarcely fit for other purposes than litter. The southern clover is of a smaller growth; and on that account makes a much better forage. Indeed, clover hay, when well cured, is very much liked by cattle, whom we must allow to be pretty fair judges in the case of what is good for them; and no long feed, that can be given to cows, will make more or better milk. One of the best milk-men in the neighborhood of Boston speaks of it in the highest terms; and, in his mode of curing prefers it to any other hay. Clover, when mixed with other hay in market, for the reason only we believe that horses taken in at livery stables, will eat more of it than of the herds-grass, cut after it is dead ripe, and so coarse and hard that the mastication of even a small quantity is likely to employ all the time the poor tired horse has to spare from his sleep; and a rack full of it, like the show pickles and pound cake at taverns, is liable to stand by for some time and to serve many a guest. We consider clover-hay, when well saved, as some of the best hay which can be grown; highly palatable, and containing an abundant nutriment; but its value greatly depends on the mode of curing.

Some farmers have cut it in the morning, and after a warm day have carried it in the afternoon of the same day, and by a very liberal salting have saved it well. But the practice of other farmers is, we believe, a much preferable mode. We know several cases in which it has proved entirely satisfactory; and we shall proceed to describe it.—They eat it in good weather, and when it is dry. They scarcely spread or stir it at all. At night of the day on which it is cut, they put it into cocks of a good size, and there let it remain two or three days rain or shine. When well made in this way, which is easily determined by a practised hand, on a pleasant day in the morning they turn over the cocks and open them slightly, and then carry it in, giving it a very little sprinkling of salt. One great object is to avoid by much stirring the shaking off of the heads. Thus cured they regard it among the most valuable hay which they get. We have known the same plan pursued by one of the best farmers in western New York with all his hay crop. The Deerfield farmers of late years dry their hay in the sun much less than formerly, and they believe to their great benefit. In all cases however the most scrupulous care must be observed to rid the hay from all wetness of dew or rain.

From the Baltimore Farmer.

RECIPE FOR TAKING HIVES WITHOUT DESTROYING THE BEES.

Having always thought that there was great inhumanity in the old plan of *destroying* the bees, in order to take the honey, we determined to try the more humane plan practised by the French of robbing them of their sweets without depriving them of life, and we have put the plan twice into operation the present season with entire success. And as, besides the humanity of the process, it has economy to recommend it, we deem it our duty to lay the method before our readers, in the hope that we may be instrumental in saving many lives of those industrious workmen, and of securing their labors to their owners for numbers of years. The method, which is easy, is as follows:

In the dusk of the evening, when the bees are quietly lodged, place a tub near the hive, then turn the hive over with its bottom upwards into the tub, cover the hive with a clean one, which must be previously prepared by washing its inside with salt and water, and rubbing it with hickory leaves, thyme, or some other aromatic leaves or herbs. Having carefully adjusted the mouth of each hive to the other, so that no aperture remains between them take a small stick and gently beat round the sides of the full hive for about 15 minutes, in which time the bees will leave their cells in the lower hive, ascend and adhere to the upper one. Then gently lift the new hive with all its little tenants, and place it on the stand from which the other hive was taken.

This should be done about midsummer, so as to allow the bees time to provide a new stock of honey for winter's use. If care be observed no danger need be apprehended.

From the Buckeye Ploughboy.

THE FARMER.

No avocation in life is more respectable and useful than that of the farmer. The time has gone by when "contempt is cast upon the husbandman." Agriculture, as a science, is becoming more important, and more honorable. It is the noblest, for it is "the natural employment of man." The intelligent and independent farmer is ever respected; he holds an important and responsible place in society. Upon him devolve many duties; upon him rest many obligations. In him we look for examples in patriotism, virtue and intelligence. Living, not in the "hum of human cities;" where he would be continually in the whirlpool of political and other excitement, he can examine questions of a moral, religious and political nature, with a cool head, a calm mind, and an unbiassed judgment. To him we look for correct opinion, and in him we should ever find a safe counsellor, and a correct adviser.

Our farmers should cultivate their minds and their hearts, as well as their fields. They can gain as rich rewards in the mental, as they can reap profitable harvests in the natural world. Without learning a man cannot be a first rate farmer. Without intelligence he cannot discharge in proper manner, the duties of a citizen. Agriculture is a science that requires experience and study. Men must be educated to be farmers, as well as to be lawyers, or doctors. And there are thousands of young men who are in stores and offices, who should go into agricultural pursuits. It would be better for them, better for the country. And who would not rather be an independent farmer, than a small shopkeeper, or a fourth rate lawyer or doctor? Who would not rather be first in a useful employment, than to be titman in one which the world calls honorable? Let young men seek for land, rather than for situations, "in the cotton trade and sugar-line."

From the Genesee Farmer.

SWAMPS.

Swamps are generally considered the most worthless and unprofitable part of a farm, when, in nine cases out of ten, if they were properly treated by draining, trenching, and being freed from bogs and bushes, they might be converted into the most valuable and productive soil. What are termed swamps are usually low lands, receiving the water and the wash of the neighboring hills, and of course must be composed of the richest materials, and those best adapted to promote vegetation. The first object in reclaiming such places, and without which all other efforts will be unavailing, is to free them from the surplus water. To do this effectually reference must be had to the extent of the swamp, the quantity of water to be thrown off, the declination of the surface, the natural outlets of the water, and the work of draining commenced on a scale commensurate with the end to be effected. If the quantity of water to be discharged is large, or if the swamp is liable to inundations, the main drain should be open, and of a size sufficiently large and deep to allow the water to flow off freely and quickly. This, as the main work, should be performed in the first place, as it will greatly facilitate the determining of the best place for side-drains, and aid in their formation. If the water of the swamp is furnished by springs around the margin, a drain of a proper depth and capacity should be run around the outside, and connected with the main drain, and if springs rise in the level part, particular reference must always be had to these places in any plan of draining. Unless the quantity of water to be carried off is very large, all the drains except the main one may be covered, and of course will form no obstruction to cultivation.

When, by draining, the surface is once dried, the operation of freeing the surface from bushes, bogs, and coarse grasses, can be carried on at pleasure. When the ground is firm enough for the use of the plough, the surface may be turned carefully over, and the cultivated grasses, clover, herds-grass, red-top, &c. sown with oats or other spring grain, to form a new and fine turf for mowing or grazing. Where the plough cannot be used at first, the bushes and bogs can be extirpated with the hoe and grubber, and the cultivated grasses sown in their stead. Potatoes are an excellent crop for reclaimed grounds, rendering the surface fine, and putting it in good condition for seeding. Swamps so reclaimed make the most valuable meadows. There is another point of view in which the great mass of vegetable mould collected in swamps possesses a great interest for the farmer. We have, in former numbers of the Farmer, stated the great care and expense incurred in the European countries, in securing the largest possible quantity of manure, by mixing with the dung of their cattle, in their stables and farm-yards, all the refuse straw, weeds, leaves, washings of the highways, and all other vegetable and animal matter that could be collected, that the whole might be used in enriching the soil and increasing the crops. As a deposit in the farmyard, nothing is found to exceed in value a covering of earth from a swamp. The custom in Belgium and Germany, where such a resource is available, is, when the yard is cleaned of manure to cover it with fresh vegetable mould or swamp earth, to the depth of a foot. This earth absorbs the urine, the wash of the yard, the salts of the manure, that would otherwise flow off and be lost, and in the course of the season, or the year, becomes the most valuable and efficient of manures. No farmer who understands his true interests, will suffer the wash of his stables and yards to be lost, and there is no way in which it is so effectually prevented, as by furnishing vegetable mould to absorb it.

With some farmers in this country who have adopted this mode of replenishing their cattle-yards, the rule is to return to the yard a load of swamp mud for every load of manure taken from it to the field. As a top-dressing for meadows or grass lands, this earth, impregnated with salts, is unrivalled for promoting fertility. Like all finely-rotted manures, its effects are more prompt and energetic than those of common manures, but the influence is not perhaps as durable. Instead, therefore, of considering a swamp as a useless piece of ground, the farmer should look upon it as a great magazine of vegetable mould; capable, if desired, of being converted into the best of manures; or if not required for this purpose, can be made where it is, to produce the best of grasses, and make the most productive of meadow-lands.

From the Genesee Farmer.

CATTLE—DEVONSHIRE.

While it may be affirmed with great truth, that the present beautiful and superior breed of improved short horns are strictly artificial, and while some fears may be justly entertained lest the valuable qualities for which they are so distinguished, have not become so fully constitutional as to be beyond the possibility of lapse,—we here bring to the notice of the farmer, a breed of cattle, scarcely inferior in quality to the short horns, and of which no apprehensions can be entertained that the type of these distinguishing qualities are evanescent, and not durably incorporated in the constitution and race.

The north of Devon has long been celebrated for a beautiful breed of cattle, in activity of work, and aptitude to fatten unrivalled. The place where they are found in the greatest perfection, is in the vicinity of Portlock and Biddleford, along the Bristol channel in the county of Devon. From the earliest records the breed has here remained the same, or if not quite as perfect in general as at the present moment, yet altered in no essential point until the last thirty years. No persevering successful attempts to improve the general character of British cattle were made until within some fifty or sixty years; and the Devonshire farmers were so well satisfied with their herds that they were about the last to dream that their beautiful red cattle could be improved, and they did not bestir themselves in earnest until the high prices and improved forms of the Collings short horns, convinced them that in estimating their advantages they were behind the age.

The most perfect specimens of the Devonshire cattle are found among the North Devons, and it is of these we shall speak. As the breed is of the middle horns the horns should be neither too high or too low, those of the *bull* tapering to the points, not very thick at the base, and of a yellow or waxen color. The eye should be clear, bright and prominent, showing much of the white, and ought to have a circle of a variable color, but usually of a dark orange around it. The forehead should be flat, indented and small, for by the smallness of the forehead the purity of the blood is much estimated. The cheek should be small and the muzzle fine, and the nose should be of a clear yellow. The *ox* has a small head, singularly so relatively to the bulk of the animal, yet it has a striking breadth of forehead. Its neck is well adapted to the yoke or the collar; the horns are small and fine; the fore-legs are wide apart, looking like pillars to support a great weight. Angular bony projections are never found in a beast that carries much flesh and fat. A narrow-chested animal can never be useful either for working or grazing.

The skin of the Devon of the pure breed, notwithstanding his curly hair, is very mellow, fine and elastic. Graziers know there is not a more important point than this. When the skin can be easily raised from the hips it shows that there is room to set fat below. The favorite color of the Devons is a blood red. The hair in some is curled, the curls running like ripples on water, and when dark giving a mahogany appearance. If the hair is smooth it should be fine and glossy. Few of good blood have any white upon them, and the pure Devon is as uniformly red, as is the pure short horn red and white.

The comparative smallness of the Devon cow, is one of the most remarkable traits of their character. The bull is much smaller than the ox, and the cow proportionally smaller than either. This is considered somewhat of a disadvantage, as it is almost impossible to procure large and serviceable oxen, except from a *roomy* cow. Owing to their peculiar build, however, the Devon cow is more *roomy* than most other breeds of cattle of the same size, which in a great measure obviates the objection. The Devon cow is particularly distinguished for her full, round, clear eye, the gold colored circle around it, and the same color prevailing on the inside of the ear. The muzzle orange or yellow, but the rest of the face having nothing of black, or even of white about it.

The peculiar excellence of the Devonshire ox, is a quickness of action in working, which few horses exceed, and no other cattle can equal. They have also a degree of docility and goodness of temper, and stoutness and honesty of work, to which many teams of horses cannot pretend. Mr. Youatt, who is great authority on the subject of cattle, thus describes their usual mode of treatment and aptitude to fatten.

The Devon steer is taken into work at about two years old; and they work until they are four to six; they are then grazed, or kept on hay, and in ten or twelve months, and without any further trouble, they are fit for market. If the grass is good, no corn, or cake, or turnips are required for the first winter; but of course for a second winter, these must be added. The grazier likes this breed best, at five years old, and they will usually, when taken from the plough, fetch as much money as at six. Lord Somerville states, that after having been worked lightly on hill land for two years, at four years old they are brought into heavy land of the vales, and used in hard work till six; and what deserves consideration is, an ox must be thus worked to attain his largest size. If he is kept idle until he is five or six, he will invariably be stinted in his growth. Mr. Youatt adds—In their disposition to fatten, very few cattle can rival them. They do not, indeed, attain the great weight of some breeds; but in a given time acquire more flesh, and with a less consumption of food, and their flesh is beautiful in its kind. It is of that mottled, marble character so pleasing to the eye, and to the taste.

As to the value of the Devon cow for the dairy, different and somewhat conflicting opinions are entertained in England. Mr. Youatt says:

"For the dairy, the north Devon must be acknowledged to be inferior to several other breeds. The milk is good, and yields more than an average proportion of cream and butter; but it is deficient in quantity. There are those, however, and no mean judges, who deny this, and select the north Devons even for the dairy."

Perhaps one of the most valuable crosses that has yet been made. is the one described by the celebrated breeder, Mr. Bolton, in a letter to the Farmer's Magazine.

"I have known many excellent beasts bred from improved short horn bulls and long horn cows; indeed I never knew one of these bulls put to any cow where the produce was not superior to the dam, but the cross which I advocate, and with which I am best acquainted, is that with the *Devon cow.* I have uniformly remarked that a cross here was attended with a proportionate improvement in size, quality of flesh, and aptitude to fatten. In every instance they have shown themselves superior milkers, and stand to the pail till within six or eight weeks of calving; and several instances have come under my knowledge, where they have never been dry since they first calved. So highly are they prized as milkers, that a friend of mine who hires out dairies informs me that the dairymen give him nearly £2 per cow per year more for the half and three-fourth breeds, than they would for cows of any other breed."

Judging from the expressions of opinions given by cattle breeders in England, by the course of the agricultural periodicals of that country, and by the fact, that at the late Smithland cattle show open to the whole kingdom, the first prizes were taken by Devon cattle, we should imagine that since the demise of some of the most celebrated short horn breeders, such as Collings, Berry, and others, the Devons were treading close on the heels of the short horns in public estimation. The first premium was given at the late Smithfield fair, to a pure Devon, the property of Mr. Coke of Holkham, and the second to a steer only 19 months old, of the improved Devon, or the Devon crossed with the Somersetshire breed. The ox weighed when dead, 1,122 pounds; and the steer when dead, weighed 1,332 pounds. The steer was a most remarkable one, and was owned by Mr. Giblett.

The Devonshire breed of cattle have been more extensively introduced into the United States than any other breed of foreign cattle, and they form a large portion, in different grades, of the cattle of New England and the middle states. Some fine stock of this breed were sent from Mr. Coke to Mr. Patterson of Baltimore, and two oxen from this importation, raised and fattened by the Messrs. Hurlbut of Winchester, Connecticut, weighed when killed as follows:

First Ox,		*Second Ox,*	
Carcass	1438	Carcass	1528
Hide	117	Hide	115
Tallow	175	Tallow	213
	1730 lbs.		1856 lbs.

Mr. Fisher of New York, addressed a letter to Mr. Coke, giving an account of these cattle, and received the following reply from that veteran agriculturist, which we insert as showing his opinion of the Devons.

Holkham, April 21, 1831.

Sir—I am this moment favored with your kind letter, and most flattering account of the Devon oxen. It is a pleasing reflection to me, that I was the first person that introduced them into America, through my friend Mr. Patterson. I thought them at that time, and I am still more confirmed in my opinion now, that they are the most superior breed of cattle in the Island, if well selected. But I beg to be understood, when I speak of the Devonshire red cattle, it is in praise of the *North Devon cattle*, with yellow noses and indented foreheads, and yellow around their eyes, which mark their character beyond that of the South Devons, which have black noses, or intermixed with black. These I beg to be distinctly understood not to recommend as a superior breed of cattle. Be so kind as to express my acknowledgments to Mr. Hurlbut, when you see him, and to assure him that I shall be at all times most happy to show him, or any of his American friends should they come to England, every attention in my power, in the agricultural line.

THO. WM. COKE.

From the Essex Gazette.

STEAM POWER.

The invention of the steam engine, and the various ways in which this philosophical and mechanical power is brought to perform the labor of men and other animals, is among the most curious and interesting subjects to which we can possibly turn our attention. Steam has already made a greater change in the pursuits of man, in the mode of travelling, and the easing of labor, than any other discovery or invention in all the history of past time, and is doubtless destined to a much more extended use; indeed, it is highly probable, that the time is not far distant, when steam engines of all dimensions and powers, will be in common use to perform domestic labor. The same fire which warms the mechanic's shop, will set his saw, his plane and his auger in motion; and we have no doubt but that the present generation will witness steam engines, perhaps not much larger than cooking stoves, driving washing machines, sawing wood, and performing many of the more laborious services of domestic life.

But it was not our purpose, in this article, merely to speculate on possibilities; but rather to state a few facts as to the power of steam and of coal expended in the generation of steam.

By a set of accurate experiments made in 1835, at the copper mine of St. Austel, in Cornwall, it was made to appear that one bushel of coal, weighing 84 lbs. consumed in the best constructed engine, exerted a force equal to raising 125,500,000 pounds one foot high, or equal to raising 1,255,000 pounds one hundred feet high; and every pound of coal exerted a power equal to raising 667 tons one foot, or more than 6 1-2 tons one hundred feet! Each ounce of coal was found to exert a power equal to raising 42 tons one foot, or 18 pounds to the height of a mile!

The largest pyramid of Egypt weighs, by calculation, 12,760,000,000 pounds, and employed 100,000 men twenty years in building it; but the whole required to elevate the stones to their present situation could be produced by the combustion of 479 tons of coal.

The Menai bridge is about 500 feet long, a single arch suspended on chains 120 feet from the water, and weighs 4,000,000 pounds; and the whole could be lifted from the water to its present situation, by the burning of 4 bushels of coal!

The burning of an ounce of coal being sufficient to elevate 18 pounds 1 mile, it requiring but 18 pounds' draught to draw two tons on a level railroad, it follows that the combustion of an ounce of coal is sufficient to draw two tons a mile, on such a road.

From these data, without any allowance for future improvements, it is easy to perceive that the principle is capable of endless diversification, and application to almost all the labors of life, and that whenever those improvements in manufactures are made, which shall afford small machines at a reduced price, they will become as common as turning lathes or grindstones.

There can be no doubt that whenever a permanent power is wanted for any laborious employment, steam is vastly cheaper than it is to employ either men or horses; and the only reason why it is not even more profitable than it is, on railroads, is, that engines of an expense and power are used, vastly beyond the labor they have to perform, and if any engine were so placed as to find employment equal to its capacity for labor, it could do that labor for half, and perhaps for a quarter of the expense of horse power; hence the utility of *extending* railroads, and bringing on new lines of travel, as almost every road in this country is furnished with steam power equal to double the amount of labor they can find to do.

ON FEEDING WET LEAVES TO SILK-WORMS.

Mr. George Fitch, of Bridgton, made an experiment last season, on feeding silk-worms on wet leaves. A few days after they were hatched he divided the worms into two lots; one lot was fed on dry or wet leaves as they happened to be, according to the weather; and when leaves were dirty they were washed and given to the worms; this lot grew faster, and became larger, and spun a week sooner than those fed on dry leaves. It required forty threads, before doubled, from the cocoons of those fed on dry leaves, to make a thread of sewing silk of rather a large size; it took eighty threads of those fed on wet leaves to make a thread about the same size. The cocoons from wet leaves were the largest and heaviest; some of them had threads 800 yards in length. The length of the threads from the cocoons of the silk-worms fed on dry leaves was not measured.

We publish these particulars, as it has been considered necessary to have dry leaves for silk-worms, and it has been recommended to pick leaves before a storm, in order to have a supply of dry leaves on hand. A few years ago, there seemed to be, according to writers on the subject, a great deal of difficulty in managing silk-worms and manufacturing silk. Close rooms, with stoves and thermometers to regulate the temperature, and dry leaves were considered indispensable; and several years' practice, with good and *costly* instruction, and an expensive reel, in order to prepare the silk for sale in a raw state. Now, silk worms are kept in barns or sheds, without any artificial heat, and they suffer no more from cold than they do from heat. So much nicety as has been practised in regard to their feed is not necessary.—*Yankee Farmer.*

MILK FROM COWS FED ON DISTILLERY SWILL.

[An animated discussion is now going on in the 'Journal of Commerce' of New York, as to the quality of the milk which forms the principal part of the supply of that city. We copy below one of the articles of the assailants. The "Committee of Milkmen" who have answered at great length to previous pieces, present but a very unsatisfactory defence, and a very poor recommendation of the commodity in which they deal.—Ed. Far. Reg.]

From the Journal of Commerce.

MILK.

The Journal cannot confer a greater blessing on this community than by producing a thorough reformation in the milk department. It is a subject in which the health and lives of thousands are involved. I have given some attention to it from the circumstance of having the constitution of a fine boy, the delicacy of whose mother compelled her to nurse from the bottle, entirely undermined, and scarred with blotches to this day; while my other children, nursed at the breast, enjoy perfect health. Uncertain of the cause of my boy's pining and drooping, it at length occurred to me to analyze the milk, which I found to be the mere dregs of a distillery; scarce one particle of nutriment to a pint. I found a pint of warm water, a teaspoon full of flour, and 2 grains of magnesia, to contain more nutriment than a pint of swill, called milk. On discovering this great secret in the milk trade, I immediately sent to Orange county and provided a young, healthy, and country-fed cow, which I have had for four years, furnishing abundance of good and wholesome milk.

It has often occurred to me as surprising, that while we have municipal laws to regulate the quality of bread stuff, the corporation should be perfectly reckless of what we administer to the delicate stomachs of our children. There is not a more sure and certain poison than this swill milk. Besides its deleterious properties, a pint does not contain sufficient nutriment to support a child. Did you ever make an estimate of the profits of the milkmen? If not, I will do it for you; having had occasion to investigate the matter. It is based upon feeding the cows on swill merely, from the distillery, which barely keeps the cows alive. The swill is given them warm, and passes through them with the same rapidity as through the stills, and is all converted into what is called milk. They are milked three times each day, and furnish at each milking from 8 to 10 quarts.

One barrel of swill costs 6¼ cents, and will keep two cows a day, which will yield on the average 24 quarts of milk. This, at 6*d*. per quart, is 1 50 cts. Every cow fed on swill yields a net profit to the milkman, over expenses of delivery, &c., of $1 25 per head *per day*. There is no branch of business so profitable, and none so baneful to a community of children. For myself, I would sooner pay 2s. a quart for milk from grass-fed cows, than take the swill at any rate.

Yours, V.

A gentleman who was formerly a distiller mentioned to us yesterday, that it was then his custom to feed cows on the slops, and that the quantity of milk, when he put them on that feed, was immediately just about doubled, but the quality ruined. He says such milk will not make butter at all. Churning only wrought it into froth.—*Eds. Jour. Commerce.*

From the American Silk Grower.

SILK CULTURE.

From information coming to us from various sources, we are inclined to believe that a disposition to try the experiment of the cultivation of silk has received a new impetus, and is prevailing in various parts of the country, with a power from which great results may be expected. The demand for the morus multicaulis, and other valuable kinds of the mulberry, has been unprecedented. The importance of the interest begins strongly to arrest the attention; and the actual importance, in our firm persuasion, is not likely to be over-rated.

The great cause of discouragement has been the destruction of the mulberry trees, by the severity of the winter. Not only has the morus multicaulis suffered greatly, but likewise the common white mulberry; so that by the unprecedented severity of the two last winters many of the standard trees in Mansfield, Conn. of many years' growth, have perished.

An experiment, however, has been made, which, by an improved mode, (for so it must be called,) of managing the plants, avoids the danger of the winter, and obtains an early return.

The land is laid out in furrows four feet apart. In these the plants, the morus multicaulis, are laid, the roots three feet apart, the roots being covered, and the branches fastened down and covered slightly with mould until they start. After this the covering is to be increased; and throwing up shoots from every bud, they form a hedge, the leaves of which may be used as soon as grown, for the feeding of the worms. In the autumn the shoots, which will then have formed trees, are to be separated by a spade or some sharp instrument, and taken up and deposited securely from the frost. The main roots, after all the shoots are cut from them, are to remain in the ground; and to be covered by turning a furrow upon them each way. These remain for a permanent plantation. The small plants which are taken up, and the shoots which are cut from the main root, may be used for forming a new plantation the ensuing season, and so on year after year. As to the trouble of taking up the plants annually and resetting them in the spring, it is not to be complained of compared with the advantages which such management promises; and is, in a great measure, compensated by the facility with which the foliage is gathered from a low hedge, compared with the labor of collecting it from high standard trees. As the foliage for the feeds of the worms will not be so early in this way as from standard trees, it will be necessary to delay the hatching of the worms. This may easily be done by keeping the eggs in an ice-house.

From the Genesee Farmer.

GEOLOGY AND GEOGRAPHY OF NEW YORK.*

The last number of Prof. Silliman's Journal, contains an interesting account of an exploration of the region around the source of the Hudson river, and a barometrical admeasurement of the principal peaks that constitute the nucleus of that elevated range, furnished for that work by W. C. Redfield, of New York, one of the exploring party, and thence copied into the Family Magazine, a valuable miscellaneous work conducted by that gentleman on somewhat the plan of the Penny Magazine, and which deserves an extensive circulation.

It is a fact no less surprising than true, that a range or rather cluster of mountains, by far the highest and most remarkable in the state, and, with a single exception, more elevated than any others east of the Rocky Mountains, should have remained for one or two hundred years, within thirty or forty miles of one of the greatest thoroughfares on the continent, without a suspicion of their great elevation, or scarcely a knowledge of their existence. The Cattskills had long been considered the highest range in the state; but it was now discovered that a part of the upper course of the principal northern branch of the Hudson was higher than the highest peak of that range, and that the source was no less then 900 feet above the Round Top. This is one of the results of the geological survey of the state—which, in addition to the great advantages to be expected from that investigation, promises to add much to our geographical knowledge, and correct many errors into which we have fallen with regard to our own territory.

The sources of the Hudson are spread over the southern part of the wild and unknown region that occupies that part of the state embraced between the settlements on the Black River, St. Lawrence, Lake Champlain and the upper Mohawk. Several thousand square miles are here nearly destitute of any settlements, without roads, covered with dense evergreen forests, abounding in lakes, and filled with animals that delight in the unbroken solitudes of nature. From Port Henry, on Lake Champlain, an apology for a road has been opened in a west direction across this region to the Black River settlements. This road crosses the main northern branch of the Hudson, about 40 miles from the lake and a few miles below the new settlement of McIntyre, which has been created by the owners of the immense ore-beds that there cross the Hudson River, and furnish a supply for the iron works in operation and erecting at that place; and it was to this place that the course of the exploring party was first directed.

The first visit was made in 1836. The party consisted of Archibald McIntyre, Judge McMartin, David Henderson, David C. Colden, Mr. Hall, state geologist, and Mr. Redfield. Thirteen miles from the lake they crossed Schroon River, the east branch of the Hudson; nine miles from Schroon they found a Mr. Johnson on the outlet of a mountain lake, called Clear Pond, the only dwelling on the road from Schroon to the Black River. Eight miles from Johnson's they crossed the Boreas River, and some eight or nine miles farther they reached the Hudson, about 8 miles below the Iron-works of McIntyre. These are situated immediately at the base of the cluster of mountains that divided the Hudson from the Au Sable.

The party immediately entered on the exploration of these wild fastnesses, which apparently had never been trodden by human foot; but the unexpected difficulties of the country, and the limited supply of provisions compelled the party to desist, after they had ascertained that the geography, natural and physical, of the district, was deserving a fuller investigation, and that the geology of that section of the state was of a most interesting character. At a later period of the year Prof. Emmons passed through that magnificent defile, the Notch, to the north of McIntyre, and measured the height of that stupendous precipice, the Wall Face Mountain, forming the west side of the defile. Nothing could equal the dreary and savage character of the country traversed by the party; and the following extracts will show the animals that range over it unmolested. "Traces of wolves and deer were frequently seen, and we discovered also the recent tracks of a moose, *Cervus Alces, L.* We also noticed, at the inlet of Lake Sandford, the fresh and yet undried footsteps of a panther, which apparently had just crossed the inlet." * * * * "Previous to reaching the outlet of Lake Colden, we had noticed on the margin of the river, fresh tracks of the wolf and also of the deer, both apparently made at the fullest speed, and on turning a point we came upon the warm and mangled remains of a fine deer, which had fallen a sacrifice to the wolves; the latter having been driven from their savage repast by our unwelcome approach. There appeared to have been two of the aggressive party, one of which, by lying in wait, had probably intercepted the deer in his course to the lake, and they had nearly devoured their victim in a very short space of time."

The second tour of exploration took place in August, 1837, and the party consisted of Messrs. McIntyre, Henderson, Hall, (state geologist,) Professors Torrey and Emmons, Messrs. Ingham, Strong, Miller, Emmons, Jr., and Mr. Redfield. They commenced their march from the settlement of McIntyre, on the 3d of August, and after a most fatiguing route reached the source of the Hudson, on the morning of the 5th. Mr. Redfield in his narrative, says, "At 8,40 A. M. we reached the head of the stream on the summit of this elevated pass, which here forms a beautiful and open mountain meadow, with ridges of the two adjacent mountains rising at easy slopes from its sides. From this same meadow which lies within the present limits of the town of Keene, the main branch of the Hudson, and a fork of the east branch of the Au Sable commence their descending course in opposite directions, for different and far distant

*This article was written in March. It having been mislaid is the cause of its late appearance.

points of the Atlantic Ocean. The elevation of this spot proves by our observations to be more than 4,700 feet above tide-water being more than 900 feet above the highest point of the Cattskill mountains, which have so long been considered the highest in the state. The course of the Au Sable to Lake Champlain, does not exceed 40 miles, yet its descent is 4,610 feet! This, according to our present knowledge, is more than twice the descent of the Mississippi proper, from its source to the ocean."

The highest peak of the mountains lies S. W. from the source of the Hudson one and a quarter miles; and the party reached the most elevated point about 10 o'clock. After clearing the zone of dwarf pines and spruces which surround the mountain, they found the open rocky surface covered only with mosses, lichens, and small alpine plants; and a clear view in every direction. On some small deposits of water in the rock, ice was found at noon, one-half an inch thick. "Around lay scattered in irregular profusion, mountain masses of various magnitudes and elevations, like a vast sea of broken and pointed billows. In the distance lay the great valley or plain of the St. Lawrence, the glittering surface of Lake Champlain, and the extensive mountain range of Vermont." Through a depression of the latter range the party discovered another, and more distant range, but whether the part seen was the White Mountains of New Hampshire, or the Franconia Mountains near the head of the Merrimack, they could not determine. The barometrical observations, on this peak showed an elevation of 5,457 feet, exceeding the height of the Whiteface Mountain by 600 feet, and the highest point of the Cattskill by 1,650 feet.

The party afterwards visited two or three other of the elevated points in this cluster of mountains, none of which equalled, in height, the one already noticed. Two of these points they named McIntyre and McMartin, and the name of Marcy has been bestowed on the high peak, a merited compliment to our worthy governor. The geological character of this nucleus of mountains is singular, as it is entirely different from that of the country or the mountains around it, and the peculiar rock which constitutes these elevated masses is not found in any other place within the United States. It consists of "dark-colored and sometimes opalescent feldspar, accompanied towards the exterior part of the formation with green angite, or pyroxene, but in the central portions the feldspar alone constitutes almost the only ingredient of the rocks. It is apparently destitute of mica, quartz, and hornblende, and also of any traces of stratified gneiss." * * "The nearest locality at present known of a similar rock, is about 200 miles north of Quebec, on the N. E. border of lake St. John, from whence it extends to the Labrador coast." It is from this coast that its name of *labradorite*, or Labrador feldspar, is derived.

The localities of this kind of rock derive more importance in a geological point of view than they would otherwise have, from the fact that the boulders so thickly scattered over the Oneida country, and more or less over the whole of the lake slope of western New York, are mostly of this kind of rock, and hence can be traced directly as it were to their original location. "The most eastern of these transported boulders, known to exist, is one of about one hundred tons weight at Coxsackie on the Hudson, one hundred and fifty miles south of the labradorite formations, and three hundred feet above the river." We have seen them of several tons weight reposing on the argillaceous range that runs through western N. York, and at elevations of from five to ten hundred feet above the Erie Canal. Prof. Hitchcock, in his valuable geological survey of Massachusetts, traces the boulders that occupy so much of that state, to their original beds, and finds the most conclusive proof that the current that deposited these masses of stone in their present location, must have flowed from the west of north; and the manner in which these labradorite boulders are distributed, not less clearly shows, when their present position and origin are considered, the action of currents powerful and extensive from the north-east. Mixed with these labradorite masses of feldspar, we have seen some few blocks of opalescent or flesh-colored feldspar, and some beautiful specimens that were a pearly white, needing but decomposition to form the valuable earth called kavlin, and used when pure in the manufacture of the finest porcelain. It may be remarked that these latter varieties of feldspar have less the appearance of rolled masses than the dark colored, or labradorite boulders, their angles being acute and apparently of recent fracture, when compared with the heavy blocks of the labradorite. From the researches of the state board of geologists, we anticipate much valuable information on all subjects connected with the geological formations of this state; particularly the position of the various strata, the localities, proofs of currents, superposition, &c.

To show the rank to which these newly discovered mountains are entitled, we have thought it might not be unacceptable to give a summary of the highest mountains yet known east of the Mississippi; we say yet known, because it is not impossible that in the tract of country we have described, mountains of equal, or even greater height, may not exist; and because the citizens in the vicinity of the Black Mountain, in North Carolina, are putting forward its claims to be considered the highest mountain in the United States. No accurate measurement of that range has, however, yet been made, so far as we know, and experience shows that the eye in estimating, or the feet in climbing heights, are not always to be depended upon. Those given are the result of barometrical observations conducted with great care by scientific men, and in most cases, repeated admeasurements have verified the correctness. We commence with some of those determined by Mr. Redfield and his scientific party.

Lake Champlain above tide-water,	90 feet.
West Moriah, Schroon River,	1,117
Johnson's, at Clear Pond.	2,000
Boreas River bridge,	2,026
Hudson River bridge,	1,810
McIntyre,	1,889
Lake Henderson outlet,	1,936
Lake Colden outlet,	2,851
Hudson River, above the Dyke Falls,	3,356
do. in the High Valley,	3,711
Source of the main branch,	4,747
Summit of Mount McIntyre,	5,183
do. Mount Marcy, or the High Peak of Essex,	5,467

The party estimated that there were not less than ten peaks within a short distance that would reach 5,000 feet; "and beside these there were not less than a dozen or twenty others that appear to exceed the highest elevation of the Cattskill group." Thus it appears that this cluster probably furnishes more peaks above 5,000 feet in height, than all the rest of the United States; though Mount Washington still deservedly wears the palm. We collect from various authentic sources the measurements of the following mountains in the United States.

Monadnock,		3,450
High Peak of the Cattskills,		3,718
Round Top do.		3,804
Mansfield Mountain, Vt.		4,279
Munroe,	White Mountain group.	4,356

Adams,		5,328
Washington,		6,237

Mr. Redfield remarks, "Owing perhaps to the lime and soda, which are constituents of the labradoritic rock, and its somewhat easy decomposition when exposed to the atmosphere, the soil of this region is quite favorable to the growth of the forests, as well as the purposes of agriculture." This opinion, so far as regards the soil, may be correct, yet it is evident that the vicinity of high mountains in such a northern latitude, must have a direct tendency, by reducing the temperature, to prevent the operations of agriculture to any considerable extent. Air cooled below the freezing point in August on the tops of mountains, easily finds its way to the valleys and plains below, producing early frosts, destructive to fruits and vegetables. Our impression is, that it is in the mineral riches of this region, and not in agriculture, that the true source of profit resides. Sprinkled with lakes, covered with the densest forests, abounding in the finest streams and water-falls, and possessing inexhaustible supplies of the most valuable iron ore, nothing seems wanting to make this mountain district the Wales of the United States, and from its furnaces and forges send forth the iron, for which millions are now annually sent abroad.

AGRICULTURE OF TUSCANY.

Extract from Simond's Tableau.

[Translated for the American Farmer, by a friend in South Carolina.]

XI. Sec.—*On the Assolemens.*—The assolement, or regular rotation of crops, forms one of the most interesting parts of the agriculture of Tuscany ; this rotation continues either during three years, and then the ground is planted five times; or four years, when it is planted seven times without ever being left in fallow. The three years' course is as follows : 1st. Wheat followed by lupines in the autumn. 2d. Wheat followed in autumn by turnips, or any other forage crop. 3d. Indian corn, millet or sagine, (holcus sorgum, Linn.) The four years' course consists of—1st. Wheat succeeded by French beans (haricots) intermixed with Indian corn. 2d. Wheat with lupines in autumn. 3d. Wheat with forage in autumn. 4th. Indian corn followed by millet or sagine.

XIV. Sec.—On turning in lupines as a manure. As soon as the wheat harvest is finished, the ridges into which the land had been previously thrown are divided into two parts, and a small harrow which is called by the inhabitants *spianuccio*, is drawn over each second ridge while the other remains untouched until the whole field is passed over. The lupine, lupinus albus, (Linn.) which is sown on the fields thus prepared, is a leguminous annual plant, which grows to the height of two or three feet, and requires no support; on the contrary, although its stalk puts forth a great number of branches, each is hard, strong, and of a very woody fibre; the flowers, which are of the size, form, and nearly of the color of those of the bean, are gathered together in large clusters at the end of each branch—and the long pods which succeed them contains the lupines, resembling large peas flattened. The lupines are planted in the month of August or September, on such of the ridges as have been harrowed, and are covered in with the hoe. The ordinary moisture of the plane is sufficient to make them germinate and grow; they are, however, commonly refreshed by seasonable rains which assist their vegetation. The lupine is generally well grown by the month of October, which is the seed time for wheat, for which it is intended to prepare the land. When it has grown to the height of 15 inches, it is ploughed in, and left to rot in the land, possessing more than any other plant yet known, the property of fertilizing by the decomposition of its leaves. The same operation of the plough, which buried the lupine, prepares the ridge for the seeding of the corn, which is then covered with a hoe; this operation of burning the lupine to fertilize the earth, is what is called by the Italians the soverciü or rovescü; it shows great knowledge of the best principles of agriculture, and succeeds wonderfully in fertilizing the earth. The peasants sow sometimes different plants for the same purpose, among others, they sow beans, but none rot so thoroughly or so fast as the lupine, nor possess the power of fertilizing in so high a degree. When it is heated in an oven or large kettle, so as to destroy its vegetation, it becomes the most powerful of all manures; it is said that three or four pounds of these lupines, buried at the foot of an olive tree, or a fruit tree that is decaying, will restore it to all its health and vigor. Careful gardeners use it, but always in very small quantities, to manure their orange trees, instead of horse manure—and produce from it surprising effects.

XV. Sec.—*Haricots, or French beans.*—Sometimes instead of lupines which enrich the earth, such farmers as have an abundance of manure, sow after the first year, French beans, which impoverish it. They are intermixed with some grains of Indian corn to support them, instead of sticks and branches. The kind of beans which bears the drought best, and is alone proper to be planted after the harvest, is marked with an eye about the germ, from which it is called faggiuole dall occhio. When these are planted, the course of cropping continues four years, because it is not until the year following that in which the beans are planted, that the farmer can sow the lupine for fertilizing the earth, by burying which, is conceived by all to be absolutely necessary.

Second year.—Forages.—After wheat harvest of the second year, the land is turned up afresh, in the months of July and August, and the forage crop is planted in September. The two kinds of forage crops most in use, are a mixture of lupines, flax, turnips, and the annual trefoil, or lupinella; it may appear strange to observe flax ranked among the forage crops, but its grain is very abundant, and easily gathered, the plant endures the winter extremely well, grows quickly, and furnishes an abundance of leaves, of which the cattle are fond. As the lupin grows much faster than the flax or the turnip, it is pulled up towards the end of autumn. When it is well grown, and after being washed, it is given to the cattle that are fond of it—notwithstanding its bitterness. The flax and the turnips, which are choked by its growth, prosper as soon as it is taken away; during the winter, these last are drawn as they are wanted. The flax is mowed in the spring, and towards the middle or end of May, all has disappeared. Among the turnips that are planted, not one half ripen, being relied upon, more for their leaves, than for their roots, in the nourishment of cattle. There are many varieties in Lucca; those that are cultivated are large and long, and of a yellow skin, such as the turnips which are called English turnips. In the planes of Pescia, they are large, flat, and colored red and rose, the produce of the seed removed from one place to another, does not resemble the plant from which the seed was taken.

In Parma and Milan, more turnips are planted than in Tuscany; in the two provinces, with the exception of the rice-fields, the assolement is for two years, and consists of wheat, turnips, and Indian corn; or if it is prolonged to three years, it is in order to plant beans or turnips, twice in the course of the third year, for the purpose of burying them in the nature of the severcio. The prodigious quantity of turnips, which covers these rich provinces, must have been very agreeable to Arthur Young, when he travelled over them. The lupinella, or annual trefoil, (trifolium incarnatum, Linnæi,) is one of the most beautiful plants, which is cultivated as a forage crop; its beautiful carnation oblong flowers, the deep color of its foliage, and the vigor of its vegetation, make it the ornament of the fields; it is planted in September, and mowed between the middle of April, and the middle of May, sometimes it is intermixed with lupines, which are taken up in autumn, its forage is more abundant than that of the flax, but it is mowed only once.

Third year.—Indian corn.—After the forage crop is gathered in, the ground is completely turned up with the spade; this work is commenced about the middle of April and is continued during the month of May; the preparation of the ground with the spade always precedes the planting of Indian corn, which constitutes the crop for the third year. It is planted during the three months of April, May and June, although it is sometimes planted as late as July, on moist spots, but there it is of a particular variety, which grows more quickly but produces less, and is called sessantino, because it ripens in sixty days. Indian corn planted in the plane, about the end of April, suffers little from drought, provided it has rain about the beginning of July, which most commonly happens. The corn is planted on large ridges with hoes, and although it is scattered with a great deal of economy, more is nevertheless put in, than is suffered to remain—this is done to provide against the attacks of insects, which often destroy it, as soon as it begins to sprout—when it is out of harm's way, the superfluous plants are taken out, and each plant is removed from the other about 10 or 11 inches on the rows, but each row is distant about 20 inches or two feet—it is moulded up twice during its growth; while it is growing it furnishes an abundant and excellent forage, of which the cattle are very fond. The Indian corn is a great resource to the people, and furnishes an excellent aliment. Mixed with wheat in bread, it gives the bread a reddish-yellow appearance, but does not injure the taste. The peasantry live chiefly on Indian corn, either in the shape of *farinata*, or *pollenta*. To make *farinata*, the meal is thrown into a kettle or porridge pot, containing boiling water, and seasoned with butter, oil, or broth, (couillon,) and salt; it is then stirred for five or six minutes, when the fire is withdrawn. It is served up as a soup, or thick couilli; the pollenta is made like the farinata, but without grease, and is more thick, so that in withdrawing it from the fire, it should be of a solid consistency; it is then cut with a thread, and placed on a gridiron over burning coals for some minutes. These two modes of using the Indian meal, have the advantage of rendering very little bread necessary; for this substance, without having too much taste, has nevertheless enough to render it palatable, without any other accompanying food. It is probable that it would be more nourishing, if it was better cooked, for the laboring people complain, that it fills them without strengthening them, while on the other hand, Count Rumford remarks that Indian corn, *well-prepared*, is the most wholesome and nourishing of all grains.

From the American Farmer.

PUMPKIN SEED OIL.

To the President of the Hampshire, Franklin and Hampden Agricultural Society.

Dear sir—As a member of your society, I deem it to be my duty to communicate to you the result of an experiment that I have made on pumpkin seeds, in the linseed oil mill.

A number of my neighbors furnished me this year with seeds, which, together with my own, made about nine bushels, and on making the experiment, I found that they produced about six gallons of oil, and probably when the experiment is tried upon a large scale, they will produce more. I tried the oil on the screw of the oil press, and find that it answers an equal purpose, to prevent friction, as sweet oil, and of course, it will be good to use on the axeltrees of carriages that are made of iron, either alone, or mixed with tar, to prevent friction. I have also tried it in the lamp, and find it to be as inflammable as lamp oil, and without the offensive smell of that oil; and the light emitted from it is of a greenish-yellow tinge, and is easier to the eyes, and, especially, when reflected from white paper, than the weak glimmering light of a candle, and of course the light is easier to read or write by, and especially to weak eyes.

I have been informed by gentlemen of medical skill, that the seeds of pumpkins have so great a tendency to promote urine in animals, as to render them unfavorable to their health; and a neighbor of mine informed me that his geese becamed so relaxed as to be unable to go, by eating pumpkin seeds. *These* circumstances induced me this season to cut open my pumpkins, and take out the seeds before I gave them to my cattle, and I found by the experiment last fall, and the beginning of winter, that my horned cattle, sheep and swine derived the greatest benefit, with the least expense to myself, of any thing that ever I tried in the agricultural line. And from the little experience that I have had as a farmer, I am induced to think, that there is no one article that is cultivated, from which so much advantage can be obtained, by so little labor, as from the cultivation and right use of the pumpkin. It is probable that the oil of pumpkin seeds may be made a complete substitute for tallow; and when it is once introduced into use, it will probably be worth at least $1 50 per gallon. Children can with the greatest ease take out the seeds when the pumpkin is cut open, with a spoon or their hands, and spread them on a floor where they will soon dry; and it is proper that they should be preserved clean, and without being suffered to mould. In the United States, where there is such an unbounded region of land, and labor above the price of produce, the main object of the farmer ought not to be the obtaining of the greatest quantity of produce, from the best piece of land, as in many places in old countries which are so crowded with population as almost to be in a state of starvation, and labor of no consequence; but the obtaining of the greatest quantity from the least labor and expense, taken together. I have no idea that fields appropriated exclusively to pumpkins would be profitable like those of corn and pumpkins planted together; for if they be planted too thick they are no inconsiderable damage to each other. There ought not probably to be more than one pumpkin suffered to grow to twenty hills of corn, otherwise they are apt to choke the growth of the corn, and not produce so many or so good pumpkins either. It costs scarce any more labor to raise corn and pumpkins in the same field than it does to cultivate it exclusively for corn, and perhaps the crop is worth a third more. On the whole, I am inclined to think that this subject is worth your notice. I am yours, &c., respectfully,

JOSIAH WHITE.

Northampton, March, 17, 1820.

From the American Farmer of 1824.

REMARKS AND INQUIRIES ON THE EFFECTS OF MARL AS MANURE.

Mr. Editor.—I find marl is becoming to be a subject of great inquiry, and is very generally growing upon the attention of the agricultural world. There is nothing which merits attention more, for in every instance where it has been applied it has been considered the most successful of all manures. There was a writer in your paper (Mr. Ruffin) who gave us one of the most correct accounts of the operation of marl on lands that I have ever seen; and further views from the same pen would still lay the agricultural interest under greater obligations to him. What Mr. Ruffin there asserts of marl correcting the acid quality in lands has been found to be true by all who have used it; and besides, he might add, that it is a great cleanser of lands, which manures are generally not—it certainly destroys all the noxious growth which puts up in acid lands, oftentimes to the great injury of the crop; and to the sheep sorrel it is certain destruction.

All the marl I have seen in Maryland is shell marl, which lies in large beds or strata, and has been generally found near the margin of the banks of rivers or creeks—this, I presume, is because it has cost less labor to find it there than elsewhere; but I have no doubt that the same strata can be found in the interior, if it was diligently searched for. They are generally from three to six feet under the surface, and present considerable variety in appearance. Some are composed of common oyster shells alone, which are very different from what are called shell banks—others are composed of what are commonly called clam shells—others of clam shells, muscle shells, and a great variety of scollop shells—others of shells so decomposed that it is difficult to class them, and these last are often intermixed and discolored with a sort of furruginous substance—others again present you shells completely broken down to lime, intermixed with sand, which of itself makes a pretty strong cement; and indeed the varieties are not only numerous and singular, but often very beautiful. The comparative effects of these different kinds of marl have not been ascertained, as they are generally different on different farms, but all agree who have used them, that the first year's product in wheat is increased to more than half as much more, but that the second crop, from one marling, is oftener more than double than less than double—this is easily accounted for upon the supposition that the marl does not become so well incorporated with the earth upon the first as upon the second tillage—but if the marl was strewed on fallow land, and two extra harrowings were given it after strewing, there can be little doubt but the incorporation would take place, and the product be improved. I find my marl acts better upon wheat succeeding my corn, than upon naked fallow, where the marl was spread on both the same year; and I account for this result, so different from what is experienced from all other manures, from the frequent harrowings I give my corn during its cultivation; for I cultivate corn principally with the harrow, as being the cheapest, most expeditious, and best implement; and my lands are stiff soils.

None but those who have been eye witnesses to the effects of marl can believe them—they are truly wonderful—old worn out clay soils, that were literally good for nothing, have been regenerated by marl alone, and present the appearance of our best and natively rich lands—and there seems to be no end to the improvement—under one marling the product increases at each cultivation, and a second marling is followed by results proportionable to the first. Such is the conviction here, as to the effects of marl, and the conviction arises from practical experience, that the discovery of a marl bank is supposed to double the value of the farm.

My principal object in making you this communication, is to endeavor to elicit Mr. Ruffin out upon this subject, whose experience, observation, and reasoning are far more satisfactory and useful than any thing I have ever met with.

AGRESTIS.

From the American Farmer of Feb. 27, 1824.

ANSWER TO THE FOREGOING.

Prince George, March 12th, 1824.

Having been some time from home, I did not until to-day, see the call on me in the American Farmer of February 27th, and the private note from you on the same subject. I feel highly gratified, that your correspondent, "Agrestis," has experience of the correctness of my opinions concerning the action and value of marl; and I am not only willing, but consider it my duty, to furnish any information in my power to give, which may be required on account of the imperfections of my former statement. I do not wish, however, to fatigue your readers, by repeating what has already been stated; and as the request of Agrestis for information, is *general*, I shall confine my remarks to the particular subjects suggested by his account, of the effects of marl noticed by him in Maryland.

Since my former communication on this subject, (contained in your 3d vol.) I have marled more than 250 acres, or about 400 in all—and my longer experience has more strongly confirmed my opinion of the value of this manure, as well as the truth of the theory of its action. But I have never obtained any results so profitable as those mentioned by Agrestis, "that old worn out clay soils, that were literally good for nothing, have been regenerated by marl alone, and present the appearance of our best and natively good lands." I still believe that the use of calcareous manures, will not be found very profitable, except on lands *not grazed*, or which are in some other way furnished with vegetable matter. On acid soils, (not grazed,) I expect a dressing of 500 bushels of marl to the acre, to increase the first crop from 50 to 100 per cent.; and under peculiar circumstances, have attained nearly 200 per cent. increase; but as all such land was very poor, even this great improvement leaves it much inferior to natural rich soils. Neither have I found that "a second marling is followed by results proportionable to the first," nor will its *mode of operation* justify such expectations. In every thing else stated by Agrestis, his experience of the effects of marl, agrees entirely with mine. The improvement is evidently progressive, and I believe, will continue to increase, until the soil is brought to its maximum of productiveness, or until the new accumulation of vegetable matter, and of acidity, cause a necessity for a second dressing of marl, which *then* will operate in the same way, and with as much profit, as the first application.

The cleansing effect of marl is also evident. The plants which are most abundant on acid soils, will thrive on no other kind; and therefore, are destroyed at once, when the soil is made calcareous. But your correspondent will not find this clean state of marled land to be permanent. One set of pests has been removed, only to allow another to succeed. *Wire-grass** is more benefited by marl, than any other plant that I know of; and the increase of this troublesome and indestructible grass, is the only injurious effect of marling, that I have yet experienced. Perhaps *blue-grass* may be considered in the same way, as I find it now on many parts of my land, where it never had been seen until within the last two years. This grass is scarcely ever seen in this part of the country, and there is not any where enough to be troublesome, except on the best neutral soils, which I suppose to have been originally marled by natural means.

Your's, &c.
EDM. RUFFIN.

[The two foregoing letters were published more than 14 years ago; and we had forgotten their existence until they were lately met with accidentally. Marling (or, properly, the application of fossil shells,) was then a novel mode of improvement in this country, and which had then been tried by but very few persons. It is, sometimes, both interesting and useful to revert to early opinions and practices, after the lapse of time may have served to test their value. It will be seen from the answer, above, that the writer even then, as since, and up to the present time, tried to abate the too exalted opinions of the *enriching operation* and *general beneficial action* of calcareous manure, no less than to establish its true action and value, and direct attention to its proper mode of application. The writer has now had practical experience of the effect of marl of more than thrice the length of time which had been gained before the foregoing answer; and yet there is but one opinion there expressed which he would now qualify, or limit, or deem it necessary to explain, to prevent its leading to error and loss. In speaking of the benefit expected of 500 bushels of marl, it should then have been stated, as meant, of the very moderate strength of the beds he had mostly used, which generally varied between 30 to 40 per cent. of carbonate of lime—generally about 38 per cent. Also—he had not then ascertained, that even of this poor marl, 500 bushels was too heavy an application for poor and worn land, and that much less marl to the acre is safer, cheaper, and much more productive of net profit. The summer of 1824 first showed the evil of the too heavy previous dressings; and the facts, and the corrected views of the writer, on this head, have been since published at length.—ED. FAR. REG.]

GREASE FOR WHEEL-AXLES.

"What is the best *grease* for wheels?" said one *whip* to another the other day. "*Tar*," said the other. "*Tar!* I despise tar, and grease *won't stay there.* Now had they put the question to our *grave selves*, we could have told them of a valua-

* The "wire-grass" of lower Virginia, is the "couch" or "twitch-grass" of England.—ED. FAR. REGISTER.

ble material to diminish friction, not only in carriage-wheel boxes, but in all machinery whatever. The composition, we believe, was first used in the iron-works on the Boston mill-dam, and consists of *soapstone*, finely pulverised, and mixed with grease or soft tallow. It is an excellent application—a real *anti-frictionist.*—Maine Farmer.

From the Newbern Spectator.

LETTER FROM THE SECRETARY OF WAR

In relation to the survey from the Southern Debouche of the Dismal Swamp Canal to Winyaw Bay.

May 28, 1838. Referred to the Committee on Roads and Canals. June 27, 1838.—Ordered to be printed.

Department of War, May 26, 1838.

Sir: With the accompanying report of the officer in charge of the topographical engineers, is respectfully submitted the report of the survey from the southern debouche of the Dismal Swamp canal to Winyaw Bay, in South Carolina, called for by a resolution of the House of Representatives of the 9th ultimo.

Very respectfully,
Your most obedient servant,
J. R. Poinsett.

Hon. James K. Polk,
Speaker of the House of Representatives.

Bureau of Topographical Engineers,
Washington, May 24th, 1838.

Sir: I have the honor to submit a copy of the report of "the engineer charged with making the survey from the southern debouche of the Dismal Swamp canal to Winyaw Bay, in South Carolina, with a view to determine the practicability of opening an inland communication for steam navigation from the Chesapeake bay to Charleston," called for by a resolution of the House of Representatives of the 9th of April.

Very respectfully, sir,
Your obedient servant,
J. J. Abert, *Lt. Col. Top. Eng.*

S. Cooper, Esq. *Acting Secretary of War.*

Washington City, May, 21, 1838.

Sir: I have the honor to report that, on the receipt of your orders of the 28th March, 1837, assigning me to the surveys near the coast of North Carolina, I proceeded to organize the requisite means for carrying them into execution. Some delay was necessarily occasioned by the scarcity of competent assistant engineers, and the necessity I was under of seeking them amongst such of the civil engineers not in the employment of the Government, as chanced at the time to be disengaged from other service. I succeeded, however, in forming two parties.

The act of Congress passed the 3d of March, 1837, required the survey to be made from the southern debouche of the Dismal Swamp canal, down the Pasquotank river to Elizabeth, thence to Croatan sound, Pamlico, and other sounds, near the coast of North Carolina, and thence by the most practicable route to Winyaw bay, in South Carolina, with a view to determine the practicability of opening an inland communication for steam navigation from the Chesapeake bay to Charleston, South Carolina. The reconnoissance of part of the line had been reserved by my original orders for another officer. Subsequently, however, the reconnoissance, as well as the survey of the whole of it, was assigned to me. No examination of the ground, however, was required before the parties began to operate in the field. The frequent professional tours of duty which I had formerly occasion to make near the coast of North Carolina, with the surveys already executed there for military purposes by officers of the corps of topographical engineers, viz: by Majors Abert and Kearney, and by Captain Bache, enabled me at once to draw up the requisite instructions to the chiefs of parties, and to assign to them the limits of their operations for the surveys requiring the earliest attention; and the time usually consumed in the preliminary examinations was whereby saved. One of the parties was directed to survey Joyce's creek and Pasquotank river, from the canal to Albemarle sound, very carefully, wherever especially there should be found a less depth than eight feet of water, and wherever any obstruction to the free navigation of the creek or river should present itself. A general examination of Albemarle sound was likewise required in the direction of Croatan sound, for the purpose of verifying the existence of a sufficient depth of water for the passage of steam vessels. This work having been completed, Core sound and the passage through the marshes were carefully surveyed, to ascertain whether any change affecting the navigation had taken place since the period of the surveys made there by Captain Bache. It was intended, also, that the same party should connect, at least by a chain of triangles, the work of Pasquotank river with that of Croatan sound, and the Roanoke marshes with Harbor Island bar—the limit of the surveys entrusted to the other party of engineers employed upon the sounds; and it was intended, also, to have taken soundings upon Long shoal, Bluff shoal, and other parts of Pamlico sound; but the advanced season, and a desire to preserve the health of the party for the prosecution of the surveys to be undertaken during the autumn of that year, joined to other circumstances, not necessary to be here stated, made it expedient, in my opinion, to postpone this part of the work to a suitable occasion. In consequence of this, the party was enabled to make the survey of that part of the line from Beaufort harbor to Swansborough and Bogue inlet before the sickly season had begun.

The other party of engineers surveyed with great care, and very skilfully, under the immediate direction of the intelligent and experienced assistant who had it in charge, the whole of Core sound; so that nothing further remains to be done there, to enable us to form the project and estimate the cost of its improvement in the greatest detail, unless it be at some suitable season during the prevalence of the storms which characterize the spring and autumn; for example, to make such observations as will enable us to ascertain the direction, velocity, and effect of the currents, which may possibly prevail there when the winds blow for a long time from the same quarter. On the termination of the survey of Core sound, I instructed the engineer in charge of the party there, to take rapidly some lines of soundings on the bar of Old Topsail inlet, the entrance to Beaufort harbor, for the purpose of ascertaining the correctness of an opinion advanced by the pilots, that since my survey of 1822 the depth of water on the bar had materially increased.

These operations being effected, and the sickly season at hand, the engineers were withdrawn from the field to plot their work, and arrange the facts which they had collected, preparatory to their resuming the surveys proposed to be made farther inland during the latter part of the fall and the beginning of the winter. We had, in a comparatively short time, collected much information; our work had extended itself to a distance of about 220 miles; and, taking into consideration the surveys heretofore made under the direction of the officers of the corps whom I have named, with the observations, the result of various professional visits to the coast, we are enabled to take general views of the character and extent of the improvements of which the sounds, at least as far westward as Cape Fear river, are susceptible; they enable us to form opinions on the question of their probable permanency; the advantages to result to the commerce of the country; and, for a great part of the distance, we have the means of estimating their probable cost. Especially is this the case with respect to the line from the Dismal Swamp canal to Swansborough. To the westward of that place, the very close reconnoissance which, in the year 1822, I made of the sounds lying towards Cape Fear river, enables us to appreciate their value with reference as well to commerce as to military defence.

The memorandum which I had the honor to submit to your consideration as the basis of a reply to the letter of the honorable C. Shepard and other members of congress from North Carolina, will have made you acquainted with my opinion upon the question of the improvement of Core sound, the value of such improvement to the coasting trade and to foreign commerce, and it will have shown the connexion of that sound with the navigable waters of the state and with the waters of Chesapeake bay. A copy of that memorandum is herewith transmitted, and I have to ask your attention to it in connexion with this report.

The practicability and importance of a navigable communication inland, between the Chesapeake bay and Beaufort harbor, viz.: by Elizabeth river, the Dismal Swamp canal, Pasquotank river, and Albemarle, Croatan, Pamlico, and Core sounds, are unquestionable. It would be out of place in this preliminary report to enter into a minute description of the sounds and rivers embraced by the surveys of the past season; nevertheless, we may state that west of Beaufort, the sounds, generally, are much narrower, and with a greater number of shoals than are those I have enumerated. Bogue sound, though broad, is very shallow. Those lying between it and Cape Fear river are, for the most part, full of marshes, through which we find the passage to be by narrow and tortuous creeks, with extremely shallow bars, wherever the tides meet in their passage from the numerous small inlets with which the line of coast is indented. The only barriers between these sounds, generally, and the ocean, are low and narrow sand-banks; over which, in many places, the waves are swept by the hurricanes; the sands are carried by the sea and the wind into the sounds; shoals are formed, and become the bases of salt marshes; the accumulation of matter over their whole area and in their channels is thus progressive. The communication between them is sometimes closed by the silt carried forward by the tides and by the encroachment of the marshes, and it becomes necessary to open small canals for the passage of lighters and canoes at high tide. To this description, which is very extensively applicable to the sounds west of Bogue, there are exceptions, which it is unnecessary for our present purpose to enumerate, unless it be required in the case of the portion of the sound lying near New river, to which I have referred in the memorandum already alluded to.

It is apparent from these facts, I think, that the question of the practicability and cost of opening a channel for steamboats west of Beaufort, or certainly of Swansborough, yields, in point of importance to the consideration of the practicability and expense of defending it against the inroads of the sea and the encroachments of the sands. The exposure, too, of this part of the route to the enterprises of an enemy, during periods when it would be most required for the security and accommodation of trade, became so apparent from the facts developed during our examination, that it was deemed advisable to inquire whether a route might not be found farther inland by which to connect the sounds and navigable waters east of Beaufort with some branch of Cape Fear river. Subsequent inquiry, supported by our previous knowledge of the country, led to the opinion that probably a canal might be constructed of the requisite capacity, and with a sufficient supply of water, from Neuse river to the north-east branch of Cape Fear river. The facts and reasoning upon which this opinion rested were verbally communicated to you; and as they received the sanction of your favorable opinion, one of the parties of engineers was instructed to make such surveys and examinations of the country, near the presumed line of communication, as would enable us to arrive at more accurate and distinct ideas of the adaptation of the ground to the project. On resuming the field operations, therefore, I organized a party for that purpose, in the stead of the one which had surveyed Pasquotank river and the sounds east of Harbor island, which had been broken up by circumstances unconnected with the service. This I placed under charge of an experienced and intelligent principal assistant, who had already served under my orders, and who performed the duty entirely to my satisfaction.

The survey commenced at a point on the north-east branch of Cape Fear river, 47 miles above Wilmington, and 5 miles below the head of navigation—8 feet water. The point of beginning was within a few yards of the mouth of Hollyshelter creek; thence it was traced nearly parallel with that creek, crossing in its course Shaking creek and several of the minor streams which issue from Hollyshelter swamp. It crossed Hollyshelter creek at Onten or Little lake, and thence followed the course of Big Sandy run to a location, the source of some of the tributaries of Cape Fear river on the one hand, and of New river on the other; thence it pursued nearly a direct route to Ward's landing, on the south-west branch of New river—length 25 miles 1,639 yards.

Thence the line coincided with the navigable waters of New river and its branches—the south-west and north-east—for a distance of 10 miles 616 yards, viz.: to Ball's landing; hence, it was traced by the way of Ethridge's mill to the head of Grant's creek, and with that creek to Whitock river, at Lee's landing, a distance of 9 miles and 1,683 yards; thence one mile and 100 yards with the river to Haywood's landing. From Haywood's the line passed through E. Jones's plantation, and along the north bank of Hunter's creek, by the southern shores of Big lake and Ellis's lake; thence down Spaight's canal and Slocum's creek to Rial's landing—20 miles and 1,012 yards. Rial's landing is one mile above the forks of Slocum's creek. From the forks to Neuse river, four miles. Slocum's creek is a broad navigable stream; it joins the Neuse 17 miles below Newbern.

The entire length of the line surveyed by the party is 67 miles and 1,429 yards, including the river and lake navigation; exclusive of these, 53 miles and 22 yards. The highest point in the experimental line between the north-east branch of Cape Fear and New rivers, was $41\frac{1}{2}$ feet above the surface water of the river at the point of beginning; but this may be materially reduced by following the course of Haw's run. Between New river and Whitock river the highest point was 43 feet, and between Whitock river and Slocum's creek it coincided with the lakes—Big lake being 38 feet, and Ellis's lake $33\frac{3}{4}$ feet. These lakes were surveyed for the purpose of ascertaining approximately their capacity as reservoirs for the supply of the summit and lockage of the canal; and we are warranted in assuming that a sufficiency of water may be found for these objects upon the summit-level.

The survey now described between Cape Fear river and Slocum's creek serves only to manifest the practicability of uniting the Cape Fear with the Neuse. Other surveys are required preliminary to the definitive election and location of the line of canal. These would probably be traced (one of them at least) between the north-east branch of Cape Fear and Trent rivers; and another, departing from Muster landing on the north-east, would follow the course of Haw's run to Shepard's mill, thence to Onslow Court-house, Moss's landing on the western prong of the north-east branch of New river, thence to Lee's landing on Whitock river, thence to Big lake, Ellis's lake, and Spaight's canal, to Rye landing on Slocum's creek. This line would be about $56\frac{1}{4}$ miles long. Its summit-level would coincide with one or other of the lakes, or, being separated from them, it would be placed in a plane sufficiently low to enable us to command for the supply of the canal as much of their water as might be deemed requisite. The summit-level would cross the navigable streams at points the least prejudicial, and it might be prolonged to any desirable extent between the points of termination of the canal.

Surveys should be made also to ascertain the practicability, the best means, and the cost of uniting the main trunk of the canal with the harbor of Beaufort by a branch traced in that direction. Its connexion with navigation on Whitock river and Neuse river would be directly effected by means solely of locks constructed at the point of passage of those rivers.

To the north-eastward of Neuse river it may become advisable to make other surveys, that we may have the means of presenting to Congress a view of all the routes by which a navigable communication might be established between Albemarle sound and the Neuse. In examining the relative merits of these, and their several claims to attention, the professional views which would most probably influence the mind of the engineer in his selection might not possibly be those to which the legislature would be disposed to attribute the greatest force. There are other reasons which may render it expedient not only to carry the surveys between the Neuse and Albemarle sounds farther inland, and which may even require us to examine more minutely than we yet have done the two great sounds, Pamlico and Albemarle. The result of such examinations might possibly even affect seriously the character for stability of a portion of the route by the sounds. How far the causes which have operated to close the inlets formerly existing in front of the sounds may have tended also to affect the depth of the sounds themselves, or whether they have had any influence, deserves to be investigated. If we compare the chart of Lawson with that of Cole and Price, we are led to believe that the depth of water off the shoals, at least, is much less than it was in Lawson's time, Nevertheless the soundings given in one or the other of these charts may be erroneous. It is desirable, I should think, to have this question settled before the adoption of any particular project involving great expense in its execution. A careful comparison of the present depth of water in all the navigable parts of the sounds I am now speaking of, with the depths noted by Lawson, Price, &c. will enable us to determine whether or not the depth is lessening in them, and if so, the periodical rate of diminution may also be ascertained. The solution of this question might possibly influence the location of the north-eastern debouche of the Cape Fear and Neuse division of canal; and however desirable it might otherwise be presumed to be to carry that as low down the Neuse as practicable, we might find it expedient, under the influence of the facts to be developed by the hydrographic survey, to carry it in the direction of Newbern, Washington, and Plymouth.

The line of canal, $56\frac{1}{4}$ miles in length, between the Neuse and Cape Fear rivers, which has been described, would suffice to open an inland communication for steamboats from the southern debouche of the Dismal Swamp canal to Wilmington, N. C., and to the ocean.

The proposed route, via the sounds and Slocum's creek, would lie parallel to the coast, and, crossing the principal navigable streams of the State of North Carolina, would be found to possess all the advantages of a general line of communication for the trade of those rivers; the rivers themselves not having usually such outlets as would enable the produce of the interior to find an exit by the way of the ocean to other parts.

The same observation will equally apply to the other divisions of the work, viz.: that of the Brunswick and Red-bluff division, as also that from Winyaw bay to Charleston.

It is obvious that such a line of improvement, especially when considered with reference to its direct connexion with some of the best harbors on the coast, is of general interest, being equally advantageous to the commerce and defence of the country.

Of the surveys made under the authority of the act of Congress of the 3d of March, 1837, there remain to be described those only which lie to the westward of Cape Fear river, between the Green swamp and the ocean. The surveys which I had formerly made near Waccamaw lake and the Green swamp, led to the opinion that if a navigable communication between the Cape Fear and Waccamaw rivers were at all practicable upon any line remote from the narrow sounds which border upon the sea, it must be traced between the ocean and the Green swamp, and that in all likelihood it should rely upon the water yielded by that swamp, and upon such as might be collected nearer the sea for the supply of the summit-level and lockage of the canal. With this view of the subject, and to test its correctness, the party of engineers which had been employed during the early part of the summer upon Core sound was, at the proper season, directed to make upon the ground I have just described, such surveys and observations as time and the means at our disposal would permit. Accordingly that party ran a guide-line of levels and a line with the compass from the Red bluff on Waccamaw river to Brunswick on the Cape Fear, 16 miles below Wilmington, and extended its observations into the swamps as far as the inundations would permit—for at that time the rains had set in.

The distance from the Red bluff to Brunswick, and consequently the length of canal, if it were constructed upon that line, would be about $56\frac{1}{2}$ miles. The examinations which the party was able to make with reference to the means of supplying the summit-level with water were necessarily very limited; nevertheless, such as they were, they were far from discouraging the expectations of success which had been created by the surveys formerly made farther inland. Whenever the necessary appropriations are made to enable us to resume the surveys, a close and extensive survey and examination of the Green swamp, and of the country lying between it and the sea, will be undertaken. When these will have been completed, and not till then, can we be authorized to form any decisive opinion upon the question, not of the sufficiency of the quantity of water yielded by the neighboring swamps and lakes, but of the practicability of conducting it to the summit-level of a canal to unite the Cape Fear with the Waccamaw. In the mean time, the probability that it is practicable is so strong, in my opinion, as to justify the department in prosecuting the inquiry.

Near Red bluff there is a shoal in Waccamaw river, at the head of tide; it is about 200 yards over, with a depth of but $1\frac{1}{2}$ foot at the lowest stages of the water. The canal would debouche below this; hence to Winyaw bay and out to sea, the only obstruction to the navigation of the river by steamboats lies five miles below Conwaysborough, at Cox's shoal, where, at the lowest water, there is a depth of six feet; the length of the obstruction does not exceed 150 yards. With this exception, there is in the Waccamaw river, below the proposed termination of the canal, at all times a depth of not less than eight feet of water, with a bold navigation, the river making good reaches, except at the "Wild Horse," about seven miles below the Red bluff, where for a mile and a half it is very rapid and crooked; and again about a mile below Conwaysborough, where the river, for about 200 yards, is also rapid and crooked, although deep.

Between Winyaw bay and Charleston we have done nothing, except to reconnoitre the country, for the purpose of becoming acquainted with the general character of the ground, and with the routes which may require to be surveyed.

From Winyaw Bay there is a passage to sea, over Georgetown bar, with a depth of $7\frac{1}{2}$ feet at low water. This bar lies far out at sea, the channel is very crooked and difficult of navigation, and the depth of water is represented to be decreasing. A project to connect Winyaw bay with North Pedee, by a canal, has been undertaken and partly executed. It is probable that the steamboat line might follow this route to the Pedee, thence to Charleston. Two lines at least ought to be surveyed; the one lying near the seaboard would avail itself of the chain of natural navigation now used occasionally by the smaller craft proceeding to and from Charleston, wherever such natural navigation might be found advantageously in the line of improvement; the other route, lying farther inland, might depart from Pedee, and following the best ground, which will probably be found upon a very direct course, to deep water on Wando river, a branch of Cooper river, on which is Charleston. The length of canal from Winyaw bay to Charleston would not probably exceed 45 miles. The ground it would occupy is but a few feet above the tide, and it would not, it is believed, require in any place a greater depth of cutting to tide-water than eight feet. It would therefore be a thorough cut, and would require none other than guard and regular locks.

I annex a schedule of maps, charts, and profiles of the surveys already executed under your orders of the 28th March, 1837. I purpose making a general map also to exhibit at one view the surveys which have been done by the department near the coast of North and South Carolina. The details of the plans for improving the sounds so far as we have the materials for so doing, as well as the calculations of the cost of the improvements, will be undertaken now, or at the conclusion of all the surveys, to accompany the final report, as may be required by your orders.

Very respectfully, I have the honor to be, sir, your obedient servant.

James Kearney,
Lieut. Col. Topographical Engineers.

Lt. Col. J. J. Abert,
Com. Top. Engs. U. S. Army.

24 sheets.

As stated in the letter addressed to the secretary of war by Messrs. Shepard, Stanly, and other members of Congress from North Carolina, I think most favorably of the importance of Core sound to that state, and to the United States, and am clearly of opinion that its channel ought to be improved, and to an extent beyond that contemplated by the act to which those gentlemen refer in their letter of the 24th of February.

The coast between Beaufort, North Carolina and the Chesapeake bay, for a length of two hundred and twenty or two hundred and thirty miles, is nearly, and in a few years, will be quite destitute of inlets capable of admitting even the smaller class of coasters. The closing of those which formerly existed, (and there have been at least as many as ten of them,) has been steadily progressive. In my opinion, (and it has been long and deliberately formed, and frequently expressed,) the maintenance of a direct navigable communication between either Albemarle or Pamlico sounds and the ocean is impracticable. I purpose in my final report, to attempt the demonstration of this proposition; and I think I will be able to show that Ocracoke, the only inlet now capable of admitting the passage of coasters, will probably also close in a few years. This inlet, which formerly had thirteen feet in low water upon its bar, was last summer reduced to a depth of 6½ feet at ordinary high tides, notwithstanding the efforts of the government to resist the encroachment of the sand upon it. By the storms of August, September, and October last, these efforts were paralyzed, and the hope of improving the inlet was abandoned.

Assuming the impracticability of re-opening and maintaining a communication between Albemarle and Pamlico sounds, at any point upon the coast between Cape Henry and Cape Lookout, we have only left for the trade of those sounds, and of Chowan, Roanoke, Tar, Neuse and other rivers, their tributaries, an opening to the north by the Dismal Swamp canal, and to the south by Beaufort harbor, at Old Topsail inlet. Between Pamlico sound and Beaufort, as stated by these gentlemen, intervenes Core sound, which is between 38 and 39 miles long, and in which are several shoals, some of them having little more than four feet of water upon them at times of very low tide

Beaufort, since the settlement of the country, has never had less than 15 or 16 feet on the bar of its inlet at high tides. It has now, perhaps, 23 feet at high tides. Certainly it has *nearly* that depth, and there are few bars to the southward of it with more; at low water it has 18 feet. A navigable communication for coasting vessels would, therefore, open for the trade of a large part of North Carolina; at least one of the best, and taking the depth of water at low tides, the character of the bar, and the safety of the coast near it, perhaps the best Atlantic harbor south of the Chesapeake bay.

Several routes have been proposed, some of them have been surveyed, and one of them has been attempted, by which to connect the trade of the sounds herein mentioned with Beaufort. It does yet not appear that any one of them combines as many advantages as that by Core sound, or that, if they were effected, the improvement of this sound should therefore be neglected.

The act of Congress to which reference has been made, proposes a depth of 7 feet at low water, and a breadth of 50 yards for the dimensions of the improved channel. The depth is, perhaps, as great as could be attained within the limits of any appropriation of money which could be reasonably expected to be obtained. The breadth is, however, insufficient for all the objects of the improvement. Two hundred yards would be required for a beating channel, and that breadth would also be necessary to enable vessels to continue their way during night as well as day.

The surveys of last year are in a state to enable me to frame a project for the improvement of the sound, and to estimate the cost of it. I have refrained from doing this, and had reserved it until all the surveys proposed by the act of the 3d of March last were completed, with the intention of presenting the whole of the subject of an inland communication south of the Chesapeake bay to the department at one view, not conceiving that I was authorized to report upon detached portions of the subject. I have, however, considered the question of the improvement of Core sound sufficiently to enable me to say, generally, that for a channel of the depth and breadth mentioned by Mr. Shepard, the cost would be somewhat about \$80,000; and for the one I have proposed about \$300,000 exclusive of any jettees or other works which might possibly be found necessary to protect the sides of the channel from abrasion, or to prevent the channel itself from shifting; but the probability of which I do not, with my present knowledge of the composition of the bed of the sound, by any means anticipate, if the larger plan were adopted.

We are not dependent upon mere speculation for our opinion of the importance of this harbor; it was made manifest by the war of 1812, '13, and '14, during which it became the depot of prizes for many of our cruisers, whence, by lighters, their cargoes were forwarded through the sounds, and by the Dismal Swamp canal, to the northern cities. Tobacco and other produce was sent by that route from Petersburg to foreign markets, whenever the Chesapeake bay was occupied by the enemy. The following extracts from the books of the treasury department will show the importance of Beaufort harbor to commerce at that period, and its contrast with the usual transactions of the port:

Years.	Gross revenue.	Tonnage.
1810	\$522	929
1811	2,681	909
1812	18,116	1,022
1813	105,214	1,041
1814	74,774	1,466
1815	4,809	1,538
1816	2,358	1,344

At the period we are now speaking of, the inland communication was embarrassed, not only by the extreme shoalness of Core sound, which still continues, but the Dismal Swamp canal had then but a depth of 18 to 20 inches, and a breadth of about 18 feet at the surface, and it was otherwise in so defective a state that the passage through it was sometimes altogether interrupted; the canal is now, or is proposed to be, — feet broad, by 6 to 7 feet deep. It is to be borne in mind, also, that Ocracoke had then about 4 to 6 feet in its channels over the shoals in the bay, and that there existed a navigable communication between Currituck sound and the ocean.

I subjoin the following statement to enable you to form some estimate of the value of the inland trade connected with the sounds which lie between Beaufort and the Chesapeake.

Amount of certain articles transported through the Dismal Swamp canal during the years 1833, 1834, 1835, and 1836.

Quarter casks wine	639
Barrels spirits	13,707
Barrels pork	5,540
Barrels flour	30,232
Barrels fish	24,522
Barrels tar	59,421
Hogsheads sugar	890
Hogsheads molasses	1,601
Bushels salt	150,905
Bushels corn	563,535
Bushels wheat and flaxseed	31,004
Bales cotton	24,091
Cubic feet scantling, plank, & lumber	960,672
Staves	23,450,211
Shingles,	100,154,475
Cords wood	8,495
Sundries, dollars	17,800

It should be remarked, that during the year 1835 the navigation of the canal was obstructed for ten weeks, and in 1836 it was totally suspended for seventy days.

The accompanying statement, prepared for me by the collector at Ocracoke, shows that 1,149 vessels, averaging 100 tons, passed through that inlet during the year ending October 1, 1836; of which 893 were bound coastwise, and 256 to foreign ports. In these last the expense of lighterage at Ocracoke was estimated at $100 per vessel.

It is known that, because of the difficulty of getting directly to sea from the northern ports of North Carolina, much produce finds its way to market indirectly through the three commercial cities of Virginia, I have not yet taken measures for estimating how much was the value of the foreign or other goods which enter the state through those cities.

I am of opinion that the improvement of the sounds of North Carolina, as a general channel of communication for the coasting trade, should not extend to the westward of Beaufort. These sounds are very shallow, and beyond Swansborough they are generally filled with marshes, through which wind narrow tortuous creeks, in which we find occasional shoals, incapable of floating at low tide a whale-boat with her crew on board. Besides which, some of them are very narrow, and the sand-banks which separate them from the sea are so low that they are equally exposed to the inroads of the elements or of the enemy.

It is along this line of coast that we find New river inlet, as well as Bogue, the inlet of Whitock river, on which Swansborough is situated.

The remarks which the gentlemen have made respecting New river are undoubtedly very sound, if their views are limited to the existing connexion of that river with the interior, and they measurably apply also to Whitock river. Should, however, a navigable canal be made, uniting the waters of Neuse river with the north-east branch of Cape Fear river (and my surveys of the past season have satisfied me of its practicability) then the importance, not only of New river and Whitock, but of Beaufort also, may be greatly enhanced by establishing a connexion between them and the canal—a connexion which their position in relation to it would invite, and one also which might be formed at an expense much below the value of the improvement to the coasting trade, and to the general commerce of the country, especially in time of war.

Memorandum of distances roughly estimated in statute miles.

	Statute miles.
Norfolk to Bogue point, Beaufort harbor *via* the Dismal Swamp canal and Core sounds,	206
Norfolk, *via* Core sound and Beaufort, to the main bar of Cape Fear river,	350
Norfolk to Wilmington, Dismal Swamp canal, Albemarle, Croatan, and Pamlico sound, Neuse river, Slocum's creek, and experimental line of canal surveyed last year ($57\frac{1}{2}$ miles) to north-east branch of Cape Fear river, and thence to Wilmington,	103
Norfolk, *via* Chesapeake bay and the ocean to Beaufort harbor, about	260
Wilmington to main bar Cape Fear river.	

An error appears to have been fallen into respecting the authority under which the surveys were made; that authority is altogether distinct from that for executing the work. But it was necessary that a survey should be made, and a plan of improvement be adopted, before the work was undertaken. It so happened that the appropriation for the special work on Core sound was made before the appropriation and authority for the general survey and plans for an inland communication between the Chesapeake and Charleston. The two duties were assigned to separate branches of the service; the execution of the work on Core sound, in the first instance, to the engineers of fortifications, as was likewise the special survey and improvement of New river; after which, and before the engineers charged with thesp ecial improvement had commenced operations in the field, came the authority and means for making the general survey &c., the execution of which was given in charge to the topographical engineers.

It would seem that New river (viz.: the obstructions to its navigation,) has been surveyed under the authority granted for its improvement; but that Core sound has not been, and that the work of improvement has not been commenced at either place, but that preparations have been made towards it, and that the work of Core sound halts for lack of a survey and plans.

Both Core sound and New river fall within the line of operations of the officer charged with investigating the general question of an inland coastwise communication to Charleston; and the sound has been surveyed, and the work has been for some time past in a state of preparation, to enable him to form a general plan of improvement, and to estimate the cost of executing it, at least so far as the excavation of the channel is concerned.

The plan of improvement which he would recommend exceeds greatly in extent and expense, as has been already intimated, the improvement contemplated by the act of the 24th Congress. It is connected with a general system for the accommodation of the coasting trade of the Union in peace and its protection during war. It has been questioned by the officer in charge of this duty, whether, on the one hand, his plans should be narrowed down to the limited object which the legislature was apparently contemplating at the time of the passage of the act of 1824; or, on the other hand whether he would be warranted in proposing his plan, or whether the department would undertake its execution without legislative sanction—a project so far exceeding in dimensions and cost the one which the act referred to had indicated.

Again, it was believed that the general interior coastwise navigation should abandon the sounds, and be carried inland, at least from the waters of the Neuse to those of Cape Fear river, although apparently the legislature deemed that it might follow the line of sounds upon the coast from Pamlico to the vicinity of the new inlet of Cape Fear. At the same time the engineer was persuaded that Beaufort harbor was so important to commerce, that it deserved to be made the principal inlet to the great sounds of North Carolina, and that Core sound should be improved so as to form an important branch of the general inland communication.

Upon so serious a subject it was to be questioned whether the department would be warranted in compromitting the legislature. It is yet a question for the department how far the selection of either of these routes for immediate execution may compromit the ultimate execution of the other.

The officer charged with the execution of the surveys asks the orders of the department to authorize his reporting on any detached portions of the work.

Should it be deemed expedient to open the channel of Core sound at as early a day as practicable, in anticipation of the destruction of Ocracoke inlet, or to provide against the contingency of war, an increased appropriation ought to be asked for so as to make the fund available for the current year amount to forty or sixty thousand dollars.

Very respectfully, &c.

JAMES KEARNEY,
Lt. Col. Top. Engs.

Lieut. Col. J. J. ABERT,
Chief Top. Bureau.

From the American Silk-Grower.

IMPORTANT TO SILK-GROWERS.

It gives us much pleasure to communicate to our patrons and the silk-growing public, the result of some experiments that we have made in the cultivation of the Chinese mulberry, considered by us of the first consequence. We have heretofore recommended, and now earnestly repeat the advice then given, that permanent plantations of mulberries should be managed according to the directions given in the leading article of our first number, viz.; to sever the trees near the ground late in the fall, and feed the worms with the foliage which will spring from the stumps and roots left in the ground the next season. We have cultivated the tree in this way, and can assure our subscribers, that it is attended with great conveniences and advantages, as it increases the quantity of leaves, and facilitates their gathering. We have about 1000 roots which have been cultivated in this manner, and they have prospered equal to our wishes, and more than fulfilled every expectation. The shoots are now five and six feet in height, bearing numerous large leaves, and the whole ground is nearly covered with their rich vegetation. Six, eight, and ten sprouts generally proceed from one stump, which will rise ten feet in height in one summer. By the middle of June the leaves will be large and sufficiently abundant to feed worms to advantage, and one man may, by passing along the rows with a sharp knife, cut off the sprouts near the earth, throw them into a cart, and thus collect food enough to supply a million of worms. In another month, there will be leaves sufficient to feed another crop of worms, thus doubling the profits of the business at a trifling increase of expenditure. We are not theorising, but stating what we have proved by our own experiments. The large profits to be derived from the silk culture, which have been promulgated by the press will be fully realized. This mode of culture almost demolishes the whole expense of collecting leaves, and increases the food for the worms 500 per cent. above what can be obtained from the cultivation of the white mulberry. But few of the American people have engaged in silk operations, and of these few, probably not one half of them have known any thing of it until the five last years. But small as their number is, they have effected greater improvements in the business than all the silk-growers of Europe have achieved in a century, and if we do not supply England with raw silk within 20 years, cheaper than she can obtain it elsewhere, it will be because there will be no country called America—no people denominated Yankees.

From the Mining Journal.

SMOKE-BURNER.

The following is a short description of Messrs. Chanter and Gray's smoke-burner, which has been publicly exhibited at their premises, in Earl street, Blackfriars, and inspected by their Royal Highnesses the Dukes of Sussex and Cambridge; the former attended by several Fellows of the Royal Society. It has also been inspected by many engineers and gentlemen interested in the progress of science, all of whom agreed in admitting the object of consuming the smoke to be fully accomplished. It will, therefore, really be a great neglect on the part of the Legislature, if manufactories and gas-works are longer suffered to darken the atmosphere of the metropolis with coal smoke. As to the parties interested in locomotive engines, they must decide for themselves; but if the estimate be correct, that they can obtain from coal a heat greater than they now obtain from coke, and at less than half the expense, it may readily be supposed that they will soon avail themselves of this patent.

Description of the smoke-burner.—It would be impossible to describe fully the nature of this invention within the limits of a prospectus, but it may be briefly stated that its principle essentially consists in so arranging the form of the furnace and position of the bars that the fuel is regularly advanced by gravitation upon inclined fire bars, without the aid of machinery, or any apparatus besides the simple instruments in common use for the management of furnaces; the carbon and various inflammable gases are set free in the process of combustion, and being more charged with the oxigen of the atmosphere and heat of the fire, proceed through and over the fire, which increasing in heat to its termination, gradually subjects the less combustible gases to perfect combustion. Saving in fuel is thus effected; for, in the present furnaces, these are not only passed off unconsumed, but, by preventing the ignition of more combustible materials, necessarily waste a large portion of the burning fuel. Thus the primary effect, in the operation of the patent furnace, may be stated to be that of obtaining, at the termination of the furnace, that intense degree of heat indispensable to the entire combustion of the various substances emitted from the burning fuel. It is needless to add, that this produces extraordinary economy of fuel. This invention is exhibited in the specification in 12 different forms, showing its application to every description of furnace. The details are somewhat varied; but the most important part of the principle, namely, the absolute combustion of the vapour is thus effected in all of them.

From the Richmond Enquirer.

BRIDGE ACROSS JAMES RIVER ON THE RICHMOND AND PETERSBURG RAILROAD.

The cars have for some weeks past been enabled to come from Petersburg to Manchester; but not to the depot in this city, in consequence of the bridge over the James river not being completed. It is, however, very nearly finished—and it is said, that the cars will be able to cross it on Saturday (to-morrow) or Monday—when the distance from Petersburg to Richmond, 22½ miles, will be run in about 1½ hour. It is impossible to speak of this splendid bridge, in terms that are calculated to do justice to our feelings. We walked over it yesterday morning—and struck as we had been, at a distance, by this imposing edifice, our astonishment and delight were augmented by a more familiar observation of the magnitude of the work and the beauty of the execution. It forms not only an ornament to our city, but it does honor to Virginia—there is no edifice like it in all America. It is 2,857½ feet long, from the abutment on the Manchester side to the one on the Richmond side. The terraced bank on the Manchester side, which connects it with the heights, is 650 feet more. The bridge is 61 feet above the low water mark of the river, and 22 feet wide—with a double rail on the top of it. It stands on 18 immense piers of granite, which was fortunately so convenient to the architect—and over the piers, is a chain of double lattice work, 17½ feet from outside to outside, and sixteen feet high, resting on the piers. These sides are formed of plank, 3 by 12 inches, crossing each other about 3 feet apart, and forming diamond shaped openings. At each intersection, they are firmly pinned with oak pins two inches in diameter. These sides are secured from the weather by closely weather boarding. Upon these the flooring rests, which is 22½ feet wide. This floor is made to raise in a curve from the outer edges of the floor to its centre, in order to cast off the water. The whole is coated with pitch and sand, making it both fire and water proof. A hand-railing is placed upon the outer edges of the floor for the whole length. The whole bridge is well braced, horizontally and transversely.

Many questions have been asked—What precautions are taken against the effects of wind, of fire and decay? The first is effectually guarded against by the mass of rock-work carried up and fitted closely between the sides of the bridge, at the top of the piers. This work is composed of stone weighing upwards of a ton and a half each, closely notched into each other, and joined with iron bands. The lateral bracing will also effectually aid in preventing the effect from wind or other forces. In addition to the security against fire by covering the floor with a composition, there will be 480 buckets hung upon the hand-railing of the passage immediately under the floor of the bridge, and kept constantly filled from the city water-works. A guard will constantly be kept to pass over the bridge before and after the passage of the trains.

The main timber will be as little subject to decay as those of an ordinary frame house, the water being excluded by the flooring acting as a roof, and the weather-boarding of the sides.

The two tracks upon the flooring will have guard-rails parallel, and raised somewhat higher than the ordinary rails, to prevent the Locomotive engine or cars from being thrown out of the tracks.

The whole cost of this bridge will be about $115,000.

The whole road and the bridge are under the auspices and superintendence of Moncure Robinson esq., a native, Virginia born, engineer. Its rock work was executed by Messrs. Benj. Green and Merrill, and the wooden work by Mr. Nisbett.

We defy any one to view this noble and stupendous bridge, without admiration. It makes one's head dizzy to look down to the river below. Around are those beautiful islets, which add such a charm to the river landscape—and above and below are picturesque views of the city, of the public buildings, and the most prominent of them, the capitol of the metropolis of the state, which will tempt the citizen to make it his favorite promenade.

This railroad, thus on the point of accomplishment, constitutes a new link in that immense railroad, which is destined to run from the Highlands of Maine to the Gulf of Mexico. It immediately connects the railroad to Fredericksburg, with the Petersburg and Roanoke road. When any one asks with a sneer, "what has Virginia done for internal improvement?" we say, "if at nothing else, look at these three railroads; and look at our noble bridge."

From the Genesee Farmer.

BREEDING OF BEARS.

The *Journal des Haras*, a French publication, in describing the breeding of cattle, horses, sheep, &c., in Russia and Poland, thus describes a source of profit but little known to the American farmer. "Some of these extensive establishments are provided with a third space, or court, enclosed by walls, and with little buildings protected by iron bars. This is destined to be a menagerie for bears of the rarest and most beautiful colors, and yielding the choicest furs. This speculation is a very profitable one. A cub of six months old with black hair pointed with silver white, yields a very light skin and fur, and which will obtain a considerable price, especially if there are others of the same variegated color and fineness sufficient to make a pelisse. A garment of this kind will sometimes be sold for $2,500 to $4,500. The skins of the old bears are employed for the carpets or linings of carriages, or the most supple of them form the clothing of the coachmen."

For the Farmers' Register.

PROCEEDINGS OF THE AGRICULTURAL SOCIETY OF NOTTOWAY AND AMELIA.

Published by request of the Society.

At a meeting of sundry citizens of Nottoway and Amelia, at Jetersville, on Saturday the 18th of August, 1838, for the purpose of promoting the improvement of agriculture in both counties,

The meeting was organized by calling Dr. James Jones, of Nottoway, to the chair, and Sharpe Carter, of the same county, was appointed secretary.

After the meeting was called to order, Mr. E. G. Boothe, of Nottoway, delivered a very handsome and excellent address, congratulating the farmers upon the increasing zeal and interest taken by them, in the improvement of their professional art, showing the value and importance of the object aimed at, the causes of the present neglected and depressed condition of agriculture, the obstacles that lie in the way of improvement, and how those obstacles and causes may be removed, to wit: By the association of farmers in every county, to consult about their own interest, which will increase their zeal, and enlighten their minds, and induce that public sentiment in favor of their profession, so essential a pre-requisite to future progress, or the obtaining of legislative aid.

After the address, it was moved by Mr. Thomas E. Jeter, of Amelia, that all persons desiring to form a united agricultural society, for Nottoway and Amelia, come forward and subscribe their names;

Thereupon, most of those present gave in their signatures.

On motion of the same, it was unanimously resolved, that a committee of seven be appointed to draft a constitution and laws for the government of this society, and Dr. Philip T. Southall, John T. Jeter, Thos. E. Jeter, and Dr. Wm. J. Cheatham, of Amelia; Col. Travis H. Epes, E. G. Boothe and S. Carter, of Nottoway, were appointed that committee.

The meeting then adjourned to meet again in the evening.

In the evening of the same day, the society met again, according to adjournment, when the committee reported the following constitution and laws, which were read and adopted by the meeting.

Article 1st. This society shall be styled "The Union Agricultural Society of Nottoway and Amelia."

Art. 2d. The object of this society shall be the improvement of agriculture, and all the arts and animals tributary to, and necessarily connected with it.

Art. 3d. Its officers shall be, a president, vice-president, recording secretary, treasurer and corresponding secretary.

Art. 4th. The president shall exercise the usual duties of his office, and enforce the rules of the Society. In his absence the vice-president shall do the same.

Art. 5th. The secretary shall keep the books and papers of the society and a record of all its proceedings.

Art. 6th. The treasurer shall collect all subscriptions, and make regular reports to the society.

Art. 7th. The corresponding secretary shall write and receive all letters pertaining to the objects of the society, keep them regularly filed, and report to each annual meeting, whatever, connected with those letters, may be important or interesting to the society.

Art. 8th. For the purpose of defraying the expenses of the society, premiums, books, agricultural instruments, &c., each member shall annually contribute not less than two dollars.

Art. 9th. Application for admission into the society, shall be made by some regular member; and the vote of two-thirds of the members present against the admission of any one shall prevent it.

Art. 10th. The president, at the opening of each meeting, shall deliver an address, or procure some other member to do it, on some subject connected with the society, or its objects; and shall appoint suitable persons, who are not competitors for the premiums, whose duties shall be to examine all animals and articles offered for premiums, and report the proper amount of premium to which each may be entitled, considering the finances of the society.

Art. 11th. No animal or article shall be entitled to a premium, unless it exhibit qualities above mediocrity.

Art. 12th. No person shall be a competitor for a premium, unless a regular member of the society.

Art. 13th. All animals or articles exhibited for premiums, shall be owned by persons living in Amelia and Nottoway, or who cultivate land therein.

Art. 14th. No animal or article shall be twice exhibited for a premium without the unanimous consent of the judges.

Art. 15th. The members shall subscribe the foregoing constitution and laws.

Art. 16th. No article of this constitution shall be altered or amended, and no new article appended thereto, except at an annual meeting, and by a vote of two-thirds of the members present.

The following is a list of animals and articles that may be exhibited for premiums, at the society's annual meeting and exhibition, which will take place for the first time, at Jetersville, in Amelia, on the second Thursday of October, 1839.

Animals.

1st. For the best stallion, considering blood, form, size and action.

2d. For the best brood mare, considering the same.

3d. The next best, regardless of blood.
4th. The bes colt under 3 years, considering blood, form and size.
5th. The next best, regardless of blood.
6th. For the best mule under 3 years.
7th. For the next best.
8th. The best jack.
9th. The next best.
10th. The best thorough bred bull, over 1 year.
11th. The next best, not thorough bred.
12th. The best calf under 1 year old.
13th. The best cow over 2 years.
14th. The next best.
15th. The best pair of oxen.
16th. The next best.
17th. The best ram, considering fleece.
18th. The next best.
19th. The best ewe.
20th. The next best.
21st. The heaviest hog under 12 months.
22d. The next best.

Articles.

1st. For the best double-turning plough.
2d. The best single do.
3d. The best large wagon.
4th. The best two-horse do.
5th. The best ox cart.
6th. The best tumbrel do.
7th. The best corn sheller.
8th. The best tanned side sole leather.
9th. The best tanned side of upper leather.
10th. The best pair of boots.
11th. The best pair of shoes.
12th. The best saddle.
13th. The best set of wagon gear.
14th. The best piece of winter negro cloth, over 20 yards.
15th. The best summer do.
16th. The best pair yarn stockings.
17th. The next best cotton do.
18th. The best piece of winter homespun, 10 yards.
19th. The best domestic carpeting, over 10 yds.
20th. The best pair of domesiic blankets.
21st. The best pound of sewing silk.
22d. The best acre of corn.
23d. The best acre of wheat.

Each article to be raised or manufactured by the exhibiter, or some member of his family.

On motion of Mr. Thomas E. Jeter, it was resolved, that four persons in each county be appointed to endeavor to induce all those favorable to the objects of the society, to join it; and the following individuals were appointed.

Nottoway.	*Amelia.*
E. G. Booth,	Dr. Wm. J. Cheatham,
S. Carter,	John T. Jeter,
Col. T. H. Epes,	Dr. Philip T. Southall,
Wm. R. Mills,	Peter Burton.

On motion of Mr. E. G. Booth, it was resolved, that the secretary furnish an account of the proceedings of this meeting for publication in the Farmers' Register.

The following officers were then unanimously elected for the year 1839. Col. Thos. W. Webster, president, E. G. Booth, vice-president, S. Carter, recording secretary, Col. T. H. Epes, corresponding secretary, Thos. E. Jeter, treasurer.

The meeting then adjourned.

JAMES JONES, *President.*

S. CARTER, *Secretary.*

LARGE LEAVES OF THE NATIVE MULBERRY (MORUS RUBRA.)

At page 275, some remarks were made on the usual delusive manner of comparing the size of the leaves of the Chinese mulberry with other kinds. We there stated that the leaves of the young native mulberry *(morus rubra)* were sometimes found of very large sizes, though the same trees, in their more mature state, would bring leaves of but ordinary size. The correctness of the sizes there stated rested upon memory only; and lest there should be some error, we have since sought an opportunity to test the facts by other and careful measurements. This opportunity was afforded a few days ago, in finding a young shoot with very large leaves, on Coggin's Point farm. It grows on one of the steep hill-sides which inclose a deep and narrow ravine. The land is covered with its original forest growth, and the young mulberry tree is over-shadowed by the neighboring large trees. The soil is not very rich, but is highly calcareous, being in fact the out-cropping of a bed of weak sandy marl. If cleared and cultivated, this part of the ground, while in its best condition, might bring five barrels of corn to the acre. It is evident that these were not the most favorable circumstances to produce the most rapid and luxuriant growth of a young tree so situated; and that if it had been on the richest soil, well cultivated, and not affected by the shade or growth of neighboring and larger trees—or, in other words, if it had been nursed as carefully as the Chinese mulberry usually is—that the growth would have been ranker, and probably the leaves would have been larger than the actual sizes, which will be stated below, and of which the actual specimens are preserved, of the four largest leaves measured.

No. 1, was 14¼ inches long, measuring from the junction with the stem, to the upper point of the leaf, and 9⅞ inches wide. Measuring by the longest straight line, which was on one side of the stem, the length was 14⅝ inches.

No. 2—	Length from stem,	12⅛ inches
	Length by longest straight line,	12⅝
	Width,	9½
No. 3—	Length, (longest straight line)	13⅜
	Width,	9⅜
No. 4—	Length, (from stem)	13½
	Width,	9¼

None of these leaves were lobed, (or cut out,) but were compact in form, and regularly rounded in general outline, except that the apex, or extreme upper point, of each was very narrow, and was from an inch to an inch and a-half long.

Of some of the leaves of each of the plants grown from seeds of the *morus multicaulis*, (described page 316,) we have made *fac-simile* representatives, by inking carefully the leaf, and taking the impression under the printing press. Of these copies the sizes of some of the largest are as follow:

Seven lobed leaves from different plants, measured—

Length	8¼ inches,	Width,	7¼ inches
"	8⅜ "	"	7¾ "
"	8¼ "	"	7⅛ "

Length	$8\frac{1}{4}$ inches,	Width,	$6\frac{1}{2}$ inches
"	$8\frac{3}{8}$ "	"	$7\frac{1}{2}$ "
"	$8\frac{1}{4}$ "	"	$8\frac{1}{4}$ "
"	$9\frac{1}{8}$ "	"	$8\frac{1}{8}$ "

Four leaves not lobed, measured—

Length	$6\frac{1}{2}$ inches,	Width,	$5\frac{3}{4}$ inches
"	$7\frac{1}{8}$ "	"	$5\frac{1}{2}$ "
"	$7\frac{3}{8}$ "	"	$6\frac{1}{2}$ "
"	$7\frac{1}{4}$ "	"	$6\frac{1}{4}$ "

The length of each was fixed by a straight line from the point of the leaf, to the junction of the leaf and the stem. The longest line, would have been to the shoulder of the leaf, and would have exceeded the central lines by from half an inch to nearly an inch. These leaves will compare well in size with any of the new varieties (except the *multicaulis*,) which have been so much puffed in nursery-men's late advertisements. Any one of these seedlings would serve, with good puffing and good luck, in skilful hands, as a stock in trade from which to sell some thousands of dollars worth of cuttings. Each one is the only individual of a new variety—its qualities totally unknown, and therefore may be announced as whatever the seller pleases—and there is no knowing how much profit may be made of its product, before it is sufficiently tried by purchasers to be known, and properly appreciated. If any one in the humbug line wishes to avail of such a chance, we will sell him our seedlings for $20 a-piece, and ask no questions. Along side of the row of seedlings, and at about three feet distance, is a row of young *multicaulis* trees, which have been treated precisely in the same manner. An impression of one of the largest leaves of these was taken, for comparison, which measures $10\frac{3}{4}$ by $9\frac{1}{4}$ inches.

From the (British) Farmers' Magazine.

DEEP PLOUGHING—TREADING IN SEED.—EATABLE PRIZE ANIMALS.

On Mr. Barker's health being given from the chair, this gentleman returned thanks, stated the great improvement in ploughing, which had resulted from the distribution of premiums, at ploughing matches, and which had amounted to £40, and after referring to other local improvements, he proceeded to say—

"I will detail to you an experiment, which I made last year in deep ploughing. I felt at first inclined to try the press, but some said try the drill, some the broadcast, and at last I selected the drill, and had the seed trodden in by my Lord Lordsdale's horses, when they were at exercise, and afterwards had a flock of 400 or 500 sheep driven over it. The produce of this land averaged seven quarters (56 bushels) and one peck an acre throughout 22 acres—(the total product amounting to £402 3s. 9d. = to $1,785, or $81 the acre,) and from two bushels and one peck of seed per acre sown; and I wish you would try the experiment of treading in the wheat, or fixing it firmly in the ground, which I am sure will lead to a similar result. As regards the exhibition of animals, I think we are still wrong in principle, and in endeavoring to produce so much fat. If we paid greater attention to the increase of *eatable flesh*, I am certain a great improvement might be effected, especially in the quality of Leicestershire sheep and pigs. When our prize animals are killed, what do we find? Why perhaps five or six inches of fat to one of lean. I intended, another year, to offer a premium for that animal which, when dead, shall show the most *lean*, and I hope that some one will offer a similar pig premium. I must beg you to take my hints about fat and lean into consideration, and see whether we cannot produce a greater quantity of *eatable meat*, than we have hitherto done."

From the Genesee Farmer.

SHEEP WORM.

There is a fly that deposits its eggs in the nostrils of sheep, usually in August and September, where it hatches, and then makes its way up into the head and often causes death. The frequent application of tar to the noses of sheep, is considered the best preventive. Put tar on boards and strew on salt, and the sheep will smear their noses with tar in eating the salt. The following method is recommended by some sheep master. Take a small log, dress it a little upon the upper side, bore holes into it with a large auger at short intervals, about two or three inches deep, fill these holes with salt, and with a brush apply tar as often as once a week around the holes, and give the sheep daily access to the salt. A small quantity of tar frequently given to sheep is considered conducive to their health. Alexander Reed, esq. of Washington county, Penn., observes, "we have long been satisfied that the use of tar as a medicine or condiment for sheep has not been duly appreciated. The cough and foul nose, I am disposed to think, are both produced from the same disease. When we notice them we lose no time in removing them from the flock, *and make a free use of tar*. It rarely fails to effect a cure in a few days, unless the animal is old or unsound."

ON THE SUGAR AND COTTON REGIONS OF THE UNITED STATES.

To the Editor of the Farmers' Register.

Alabama, August 16th, 1838.

I propose (as an inquiry of some interest) to give some general views of the most suitable regions for the profitable culture of cotton and sugar, and, incidentally, of corn and potatoes, wheat and the small grains. The sugar region may be considered from towards the equator to latitude 31°. The cotton from 31° to 35°. Corn, wheat, and the grasses, from 33° to 40° and beyond. A correct comparison of the profits of each, in their most suitable situations, will approximate them much closer than on a superficial view might be thought. I shall commence with the cotton region, as that with which I am best acquainted; and be more full on it, as my own opinions are at variance with what I believe the general opinion. That opinion is, that cotton will not be a productive crop below 31°, whenever it shall be the general crop of the country, and that beyond 35°, the climate is too cold for it. Suitableness of soil and judiciousness of cultivation combined, may make some exceptions; but it will be found generally correct. Light and free soils, in Virginia and North Carolina, above 35°, may make it occasionally the interest of the proprietor to cultivate cotton; but he must connect with it something else for market: for he cannot make one half as much cotton as an equally judicious planter, on an equally fertile plantation, under the best location as to climate. But why should this be so? Why, because the stalks will not produce so much; but the principal reason is, that the early frost does not as with us merely kill the leaves and tender limbs, and check production, but it kills the plant entirely, and all its sap, and sours it, and the wool dies, and loses its elasticity, and dries, and becomes very much lighter. It is difficult to say what is the loss in weight, and I have no means of correctly ascertaining. I feel very certain, however, that the loss is more than one-fifth, and, I believe, more probably one-fourth, where it remains in the field the usual time necessary in a good crop. When the stalk is dead entirely, the wool loses its vegetable oil, its weight, and its elasticity, and the trash adheres to it, so that it picks clean with difficulty. We know this so well here, that on the rusted parts of our fields, where the stalk is dead and dry, and all the leaves gone, notwithstanding a fine show of wool, it is passed over unpicked, where the crop is a large one; and the laborers seldom get half weights when they do pick it, though their baskets are nearly as full. It is usual to weigh in the cotton as it is gathered; and if we get one pound of clean ginned cotton to every five, we do well; and we know that dried seed cotton will give one pound for every three. Some allowance is to be made for the wet from the morning dews; but still much arises from the drying of the oil out of the cotton fibre. It dries much faster, of course, in the field exposed separately to the sun. When it has been long so exposed that all the oil is gone, the cotton becomes blue; and it is equally so where the cotton pod stands too high on the stalk to be affected by stains from the earth.

Another reason—we begin earlier to pick, and can continue to pick later in the year. We commence about the 20th of August, and in 35° they commence about the 10th of September; and that difference of time, when the cotton is heavy, and the days are long, is good for 400 to 500 pounds of clean cotton, or one bag to each laborer. We can and do pick more where the climate perfects the pods, if these fully open and eject the whole, or yield it to the slightest touch of the picker. Crops vary from 1500 pounds to 4000 pounds of clean cotton to each laborer; and I suppose them to range in 35° from 1000 to 1500 pounds. To speak of averages, I would say, in 35° the crop should be 1000 pounds, in 33° and thereabouts, 2000 pounds, both under reasonably fair circumstances. 3000 pounds and upwards have been but very rarely gathered without much additional assistance. I do not consider it difficult to grow that quantity on a really fine plantation; but I think it impossible to pick it with the same persons only that made it. I have seen 40 acres of unpicked cotton ploughed up in March, that would have given 1200 pounds or 1500 pounds of seed-cotton each acre; and the gathering, with much assistance, did not reach 3000 pounds to the hand. I therefore am incredulous as to these great gathered crops.

So much for the unsuitableness over 35°. Now let us inquire into the reasons why it should be so under 31°. I have supposed, that in northern latitudes plants depend more on the soil, and in the southern more on the climate. In the former, there is a general tendency to bear fruit; in the latter, wood and foliage: and that latitude is best where their mutual action best suits. Below 31°, the fruit-bearing tendency is overcome too much by wood and foliage. You must have a reasonable size of stalk, to have abundance of fruit; and the fruit-bearing tendency must not be too little. Another reason may be, that without a winter severe enough to destroy the larvæ of insects, you are more liable to their depredations. I do not know that I make myself understood; my reasons are but speculations, and are not very satisfactory to myself, and will probably be less so to you. In the warm climate of the West Indies, cotton was much more grown than it now is. Of South America we know too little to seek for examples either way. Formerly it was very much and profitably cultivated on the seaboard of South Carolina and Georgia; it is at this time very little cultivated. It has been rather a poor product in Florida, and is each year getting more so. It runs too much to weed, and the ravages of insects have increased. I shall adduce two strong facts from this and the adjoining state of Louisiana, and which first led me to this opinion. In 1819, a large and very fertile body of lands on the Escambia, just above the West Florida line, above and near latitude 31°, was settled by several of our very best farmers, and their crops, for several years, were large and remunerating. The general cultivation of that neighborhood, and its continuance, have occasioned the plant not to yield so well, though still exuberant in its growth; and it has introduced insects, that have preyed so much on their cotton, that almost every one of those planters has left that neighborhood and gone higher up into the country. The crops above 31° in this state, are less productive, and more injured by worms, than formerly.

The second is, that cotton, below 31°, is no where now cultivated to any extent. The fertile banks of the Mississippi, from the Balize to 100 miles above New Orleans, has but very few plantations where cotton makes any portion of the crop. It is a fact, to the notoriety of which I appeal, that it is considered there unsuitable for cotton. A more fertile soil, or better fixed plantations, or better cultivators on them are to be found no where. On the same river, from about Natchez, in, and upwards, it is a superb cotton country.

It is said Texas is a fine cotton country. This is rather an expression of an opinion of what it will be, than what it is. It has not had time to establish its exemption from what has been the fault of all the countries under a similar climate—that its cotton will grow too much to wood and foliage, and that it will be depredated upon, too much, by worms and insects. I allude to the seaboard of Texas. It is the true sugar region, (and the indigo country, for the same reasons,) and that in time, will be its staple product, so soon as the security of the government and the inconveniences of a new population, and a new country, shall overcome the prudence and caution of the more wealthy planters elsewhere. My paper and your patience are both about to give out, and I must be brief on the other topic, and exclude the last altogether. The sugar region, I consider below 31°, where the climate is very hot; the cut cane acidulates, heats and rots, and, therefore, you must haul as you grind. In Louisiana, on the approach of frost, you may cut a three weeks' supply, and will make sugar without rot, and without acidulation. In the United States, there is properly no sugar country; the plantations on the seaboard, beyond and on the Mississippi, to the parallel of New Orleans, can only, and can scarcely be called such. The crop is a hazardous one, and the sugar interest is a debt; it is a forced crop, and the mode of cultivation of the best planters shows it. They push the early growth, and drain well to keep from the cold occasioned by the transpiration water, through and under their levees, the river being then generally higher than the surface of their cane fields. Cane planted in October, is better than in the spring. The cane requires a strong soil and a long season, to give the maturity, and that degree of richness or saccharum to the juice, that makes the sugar. New land and late canes give equally large stalks; but the saccharum is not there, and sometimes so deficient, that it will only make molasses. Where, above New Orleans, sugar is successfully made, as in the La Fourche, the Terre Bonne, &c., there the soil is very free, and hastens the maturity. As I have said before, the true sugar country is Texas; and when society and security, and health and good government, shall have overcome the caution of the more wealthy, it will be a splendid country, and the future El Dorado.

A PLANTER.

From the Edinburgh New Philosophical Journal.

ON THE FROZEN SOIL OF SIBERIA.

By Professor Baer of St. Petersburgh.

It has long since been ascertained, says M. Baer, that over a great extent of country, the soil of Siberia is never entirely free from ice; during the summer, the surface of the ground is, to a greater or less depth, thawed; but at some distance from the surface, a bottom of perpetual ice is met with. Gmelin, the elder, in his travels in Siberia, states that shortly after the foundation of the town Yakutzk (in latitude 62½° north; longitude 130° east nearly,) at the end of the seventeenth century, the soil of that place was found to be frozen at a depth of 91 feet, and that the people were compelled to give up the design of sinking a well. Many other facts of this description were collected by travellers about the middle of the last century; but these facts seem not to have been generally credited; and even in 1825, Leopold Von Buch, a philosopher, whose opinion is of the greatest weight in all questions connected with the physical condition of the globe, rejected these statements as entirely erroneous; yet they have been corroborated in our days by the travels of Erman and Humboldt. Until very lately, nothing was known respecting the thickness of the frozen surface; but within these few years a merchant of the name of Schargin, having attempted to sink a well at Yakutzk, was about to abandon the project in despair of obtaining water, when Admiral Wrangel persuaded him to continue his operations till he had perforated the whole stratum of ice. This he did, and kept a complete journal of his work. The well, or pit, of M. Schargin had been sunk to the depth of 382 feet, and at that distance from the surface, the soil was very loose, and the temperature of the earth ½° Reaumur, (31° Fahr.,) but nearer the surface it had been much lower, and had increased as follows: Reaumur, 6° at some feet below the surface; 5° at 77 feet; 4° at 119 feet; 2° at 217 feet; 1½° at 305 feet; ½° at 350; ½° at 382 feet. As the soil had already become loose at 350 feet, and as the aperture of the well was eight feet square, and the work carried on partly during winter, when, of course, the column of cold air must have rushed into the pit and chilled the temperature, it is probable that the spot at which the thermometer marked the freezing point, was at the depth of 350 feet. This immense thickness of ground ice would prove that Siberia must have been for a long period in the same physical condition as it is at present. In the actual state of our information on this subject, it is impossible to determine how widely this layer of ground-ice is spread under the surface of Siberia; yet we know enough to say that it extends over an immense tract of country. Humboldt found the soil frozen at a depth of six feet at Bosgolowsk, near the Ural, in 60° north latitude. Near Beresow, Erman found the temperature of the earth at a depth of 23 feet, still+1°.6, (35½° F.,) but in 1821 a dead body was disinterred, which had been buried 92 years before; the earth around it was frozen, the and body did not show any signs of decomposition. It has long been known that at Obdorsk, in north latitude 68°, the ground is always frozen. Near Tobolsk, no ice is found in the soil, but as we proceed to the eastward, the ground-ice advances farther north. It is to be hoped that measurements of the temperature will shortly be made at different depths at Yakutzk, and by methods which M. Schargin was unable to employ; also it is desirable to institute an inquiry as to the depth at which the ice annually disappears near the surface, and collect information on the depth of ground-ice generally in Siberia. It would also be highly gratifying to me, and extremely interesting to science in general, if the Geographical Society of London, would collect information respecting the extent of the layer of ground-ice in North America, the thickness which it attains, and how much of it disappears by the summer heat, in those countries over which the factories of the Hudson's Bay Company are disseminated. At the termination of the reading of this paper, an animated discussion took place on the frozen soil of Siberia, in which the members stated their views on the subject. It appears to be generally considered, that the experiment at Yakutzk had not been made with sufficient care, to authorize the belief that the frost penetrates to so great a depth as 350 feet below the surface of the globe; also that the statements of M. Arago and Von Buch, and others in our own country, on the increase of temperature in proportion to the distance from the surface, were fully borne out by the observation of M. Schargin; and almost exactly in the same ratio as hitherto found. Captain Back stated, that in his many years' experience in the cold regions of North America, even in the height of an arctic summer, he had never found the ground thawed more than four feet below the surface; but that experiments on the subject were much to be desired.

From the Farmers' Cabinet.

MILCH COWS.

The attention of farmers is invited to the consideration of the character and condition of our milch cows.

How much ought a cow to yield to be worth her keeping? What is the average time that our cows are in milk? Is there much if any waste of fodder among us by keeping cattle that yield little or no return of profit? Questions like these, and there are many such, ought to be put and answered: it may turn out that our dairy stock is extremely low in character, and its management wasteful.

If something like an average quality of milch cows could be settled to afford a standard, and it should be understood that no good farmer would keep an animal for milk that fell below it, all the cows in the country would soon come up to the standard and go beyond it.

A milch cow of *medium* quality, in this state, will give, it is supposed, 12 quarts of milk per day for two months after calving, and 7 quarts per day on grass for the next 4 months, and 4 quarts per day for the following 2 months, and perhaps two quarts 1 month longer. Altogether 1500 quarts, in a year.

It takes 9 quarts of milk to make a pound of butter, and 4 quarts to yield a pound of cheese. The skim milk and dairy whey may be valued at $3 a cow per annum.

Now a cow that gives 1500 quarts of milk in a year, produces 166 pounds of butter, worth 16 cents per pound, $26 55
Skim milk say 3 44

$29 99

Or 1500 quarts of milk will give at four quarts to the pound of cheese, 374 pounds, which at 8 cents per pound will be $30 20
Whey, say 3 00

$33 00

Nothing is said of the worth of the calf, as all the milk the cow gives is credited. A milch cow's keeping one year cannot be short of $25 in the interior.

Suppose a farmer to resolve that he would keep no cow that did not hold out a good milker, 9 months in the year—and that did not give 16 quarts of milk per day for two months after calving, and 12 quarts per day the next four months, and six quarts per day the next three months, and two quarts per day the month following. Such a cow would yield per annum 3000 quarts of milk.

Here it may be remarked, that with the addition of five dollars per annum to the cost of food estimated for a cow, the net profit would probably be four-fold.

Is it not practicable to have throughout the country, as common dairy stock, animals as good as the last described?

This question is submitted to farmers for consideration. The probability is, that in taking some pains to get stock as good, they would get even better.

If the various modes of obtaining this object were resorted to at once with zeal throughout the country, there would be a prodigious improvement in a very short time. No young animal of promising appearance for milk would go to the butcher. More care would be taken of young stock. More young stock would be retained to insure a better selection for milch cows. Farmers would think more of the advantages of employing bulls of the improved breed. Heifers would be milked with great care and very thoroughly, to get them into the habit of holding out longer as milkers. If they once dry early, no care and keeping will afterwards correct this fault. Heifers with the first calf will be fed well, and with some additional care, the last three months they are in milk, to make them hold out.

The profit of a milch cow is not generally understood. Milk is not only the most nutritious, but the cheapest article of food. The food necessary for a cow in full milk, does not exceed in price, one-third of what is necessary in feeding for the butcher.

These few remarks are hastily made to draw out farmers on this subject. There is a great deal to be said upon it, and a great many facts to the purpose, which should come to light.

MEMORANDA OF LIMING. PROPOSED LEGISLATIVE PREMIUM.

To the Editor of the Farmers' Register.

Charles-city County, August 15, 1838.

In my memorandum book I find the following sentences, which, if they will be of any use to those who are using calcareous manure, or beginning to do so, they are very welcome to them.

I commenced the use of lime in the year 1823 at Weyanoke; put on at the rate of half a bushel of burned shells to every 18 feet square; do not think I ever had any increase of the corn crop the first year; have observed it always looked greener. Never failed in a crop of clover on limed land, no matter how poor, or how much galled or gullied. The most benefit ever received from liming, was on a broom-straw old field; first burned (the straw) then limed before ploughing, at the usual rate. Suffered to grow up again in broom-straw; ploughed in the spring and suffered to remain till the fall; fallowed and put in wheat; (a poor worn-out reddish soil, rather sandy;) it produced 15 bushels of wheat; a fine crop of clover succeeded—then wheat (lost by rust)—corn, a fine crop, about $6\frac{1}{2}$ barrels; (wheat entirely destroyed by the previous winter;) clover, a fine crop; wheat, 26 bushels to the acre; now in corn of an unusual large growth, much affected by the present drought, but will, I venture to say, produce between 5 and 6 barrels of corn; a good season would produce over ten; has never been manured; plastered once in the spring, the year after it was limed. Have been in the habit every year of mixing lime with manure, always with increased benefit. For the last four years have used marl in that way. I believe one hundred bushels of marl, such as is got from Cabin Point, or Coggin's Point, will do as much permanent good as 300 put on alone; it ensures a great growth of clover, and I think the sooner the vegetable matter is applied after the application of the calcareous matter, the greater, quicker, and the more permanent the advantage to be derived.

On an acre of land, in a field I have limed of 150 acres, I put one peck of lime or burned shells to the 18 feet square; on an adjoining acre I put one bushel to the same area, marked with cypress shingles; have never been able to discover any difference. The field has been in corn twice, in wheat twice, oats once, and clover twice since. I have showed it to a number of gentlemen. I have limed different pieces of land, twice for four years in succession, putting on the same quantity as at first; have never seen any advantage resulting to the crops. I think the use of lime has lessened our liability to autumnal diseases. On all crops lime is beneficial the second year; oats and peas, I think, it improves the first year. One hundred bushels of marl with the quantity of manure necessary for turnips, on one and a half acre, will produce twice as many as the same land with the manure only; the marl to be well incorporated with the manure, and mixed some 4 or 6 months previous. This mixture is the finest manure for celery; renders it sweet and very tender, increases the growth one-third.

I have put lime on the surface, harrowing it in only, ploughed it in with small ploughs, with four-horse ploughs, and at all seasons of the year; have never discovered any material difference; concluded it was only necessary to use it, no matter how, where, or when, and the tide-water region of the Old Dominion will rise, phœnix-like, with increased health, and wealth. Already has our assessor, Mr. William Tyler, affixed nearly one-third on the value of my land since the last assessment; and I assure you he is a judge in those matters, being one of our most intelligent and successful farmers, and one who has been intimately acquainted with my lands his whole life. As this is an instance of advantage to the state, and there are twenty such other cases in this county, would it not be advisable that the legislature should offer a premium equal at least to the increase of the amount of taxation for calcareous improvement of every ten, twenty, or one hundred acres? In twenty years, I would lay a wager, no farmer in the marl and lime regions of Virginia, would have a note in any bank, or any other note which he would not be able to liquidate at maturity. And it would do more to lessen the necessity of banks than any other law they could pass, for the very reason that farmers would have no necessity for them; and being able to be always punctual in their payments to merchants, it would lessen very much their (the merchants') demands on the banks.

JOHN MINGE.

From the Farmers' Cabinet.

DESTRUCTIVE INSECTS.

Not only thorns and thistles, but hosts of noxious insects have been inflicted on degenerate man. My attention has been chiefly directed against the latter evil.

The character of some of these insects will be described in treating of my warfare against them.

The Peach Insect.—The first in my series, is probably of American origin, as in no system of entomology can I find a description of the insect which has proved so destructive to our peach trees. I have to rely on my own observation for its history and description. It was probably unobserved by us prior to the present century.

In the autumn of 1800, I first saw the fatal malady in the peach trees about Philadelphia; the next year it had reached Burlington, and thence continued its march northward about twelve or fifteen miles a-year. In 1807, in a choice collection of fruit of my own, every tree had the premonitory symptoms of the yellows: a few miles north escaped that year. Having made a careful dissection by splitting and barking several trees, I could discover no cause, but ravages of the worms between the bark and wood. Collecting a number of the worms, I confined them in glass and hatched from them the perfect insect; moth or miller, small in comparison with the worm; white or light gray, with dark spots, wings convolute, like the section of a crow-quill split longitudinally. This phaleua or moth lays its eggs on the leaves of the peach tree; when hatched, the larva or maggot subsists itself first on the leaf, until it has acquired sufficient size and energy to migrate to a more suitable and permanent home for winter: this is between the bark and wood of the tree near the ground. Here it enlarges its domicil; a sickly state of the tree follows, and if they congregate in sufficient numbers to circumvent the tree, certain death is the consequence, by intercepting the communication between the root and body of the tree.

The larva of the peach insect is herbivorous, and in this state of existence subsists on the tender lining of the bark; living in a cleanly manner, it deposits all filth outside the door, by the dark powder appearance of which its abode may be detected. In its chrysaloid state, its appearance is smooth and glassy. It frequently happens when seeking these worms, a chrysalis very different is found; this is the sirex or tailed wasp, the natural enemy of the peach worm, the sirex is a restless, fidgety insect, resembling the wasp; its young, like that of the other wasps and hornets, is carnivorous. It may be observed about the neighborhood of the peach worm's habitation, at the door of which it lays its eggs; the product, a worm, creeps into the bowels of the peach-worm, feeds on its carcass, and occupies its coat. Its chrysalis, unlike that of the peach-worm, is rough and filthy, caused by the sweat and writhing of the victim of its rapacity.

I have been thus particular in noticing the sirex, because, being a usurper of the abode of its foster parent, it has been falsely accused of being the mother of mischief, instead of a friendly ally, which should be patronized. Among others, the Sussex New Jersey Register, had, about six years ago, a belligerent article against this supposed enemy.

Knowing that, even in a moderate degree, *heat* proves fatal to the cut-worm, I was led to try its effect on the peach-worm; having placed several in the hollow of my hand, I found that water not uncomfortable to my skin, killed them. I thence commenced applying boiling water from a watering pot, (without the nose,) pouring it around the tree, about 18 inches above the ground in sufficient quantity to heat the bark; the quantity was varied according to the thickness of the bark and size of the tree; this proved completely successful for several years, and as long as it was continued.

The time for using the heat, was the last of summer, and again the middle of the autumn, lest some might have escaped or more recently arrived.

The Cut-worm.—This is the offspring of the *phulana devastator;* wings horizontal; white with small dark spots; under wings orange; conceals itself from the sun during the day; lays its eggs near the root of grasses. These worms are of a bluish color, and they travel only in the night; they cut off young cabbages, beans and corn; the latter injured but not destroyed by them.

To shun its depredations in gardens, be careful to plant at a distance from any grass plot or lawn. I have lost an entire crop of late-planted beans by them, by planting near a grass plot. Frequent superficial hoing, in the middle of the day, by exposing to the sun, proves fatal to many of them.

Turnip fly, is another familiar enemy. I have witnessed many a crop of cabbages and cauliflower plants, also melons and cucumbers, destroyed by these minute insects. To obviate this, on the first mentioned small seeds being sown, I have wetted the ground to the depth of an inch or more with boiling hot water, thus destroying the flies and their eggs, and at the same time expediting the germination of the seed. For melons and cucumbers I sow and rake radish or turnip seed, on and around each hill; the flies are attracted by these, their more favorite food, from the melons, &c. Against the striped bug, another destroyer of melons, a brood of young chickens is a sufficient protection for a whole garden.

I do not persume to think the above the only or best means of abating the evils we suffer from insects; my object is rather to elicit from others the result of their observation and experience; the subject, in my view, is important. Has any one, more fortunate than myself, discovered the insect, for insect it most probably is, that produces the deforming warts and threatened destruction of our plum trees?

A knowledge of the agent might lead to the means of counteracting the influence. May we not hope that some means may be discovered for palliating the impending evils from the wheat insect, by fire or smoke of some offensive kind, as of horns or hoofs of animals, made in the evening, at a particular stage of the opening ear. Many remedies and some of much practical utility have been suggested against the Hessian fly. We ought not to submit to nor look lightly on these pests.—Ants, insignificant as they appear in our view, have been suffered to multiply to such an extent on the island of Granada, that a premium of £2,000 sterling has been offered from the public treasury, for the best plan of their destruction. Poison and fires are employed.

Let us exert our energies against the whole race of these *destructive insects;* let us devote a few hours each year to this warfare, and although we may not gather laurels, we shall assuredly reap a rich bounty. SENEX.

Kinderhook, March, 1836.

BULLETING AS A SUBSTITUTE FOR SPAYING.

[At page 285 of this volume we republished an article in recommendation of "bulleting" as a substitute for spaying. The following extracts, from another and more recent source, serve, the one to contradict, and the other to leave questionable, the utility of the substitute before proposed. But in addition to this ground of value of the letter of Mr. Smith, it deserves republication, with marked commendation, as exhibiting the rare merit in a writer of coming forward, voluntarily and readily, to confess that he had been in error in a previous communication, and that under that error, he had been aiding to deceive, when he meant to instruct his brother farmers. Many, in due time, have discovered that they had previously published erroneous opinions; but few have enough moral courage and sense of duty to make the proper atonement.—ED. FAR. REG.]

From the Franklin Farmer.

Midway, Woodford Co., Ky., Aug. 15, 1838.

Dear Sir—The object of writing communications for the public should be to diffuse useful information, and they should, therefore, only convey *facts.* Errors which are likely to have an evil tendency, should be corrected. False theories and half-tried experiments, though frequently promulged from the purest motives, often do great injury; and yet to hold the secret possession of facts, hoarded up for the purpose of selfish emolument, without regard for the good of others, is mean and selfish in the extreme. Taking the position, that it is the duty of every one, to do as little harm and as much good as possible, I hasten to correct, and thereby counteract the evil effect that might be produced in consequence of a recommendation which I made, of bulleting sows instead of spaying them, under the signature of "Woodford Farmer." Although Mr. Davis was successful, in his first operations, others have been unsuccessful, and I have undoubted authority to state that bulleting *will not answer* as a substitute for spaying, which, in justice to myself, as the author of that recommendation, and for the public good, I hereby make known the facts as communicated to me.

BIRD SMITH.

Remark.—We have known bulleting to succeed well. It would be an inquiry well worthy of attention, to ascertain the circumstances under which bulleting, as a substitute for spaying, both succeeds and fails.—*Ed. Fr. Farmer.*

From the Franklin Farmer.

RENEWING OLD HANDSAWS.

I am in possession of an improvement which, if you think worth communicating to the mechanics and farmers, is at your service. In the year 1813, in Harrison county, Ky., I had a very fine handsaw, which some of my apprentices rendered unfit for use. She had what is termed by mechanics, a spring or broken back, or joint in her, and was thrown by. I tried several experiments to remove the spring and at last fell on the following plan:—I took a blacksmith's hand-hammer with a smooth face and laid the saw on a smooth anvil, and hammered it lengthwise where the spring or joint seemed to be. I hammered it in the centre of the width, which removed the joint, and she was straight and stiff as ever, and was no more liable to have a spring or joint than any new saw, and performed as well as usual. If the hammer and anvil are smooth, no one will ever observe that it has been done. I have straightened a great number of useless saws thus and made them good as new, and have communicated this method of doing it, to many of my brother mechanics in Kentucky and other states. And now, as a mechanic and farmer, have thought for several years of having this information published to the world, for there are thousands of handsaws thrown aside as useless, for want of a knowledge how to restore them to usefulness.

J. H. WENTWORTH,
Millwright of Kentucky.

From the New Hampshire Silk-Grower.

PROFIT OF DEAR LIME USED AS MANURE.

Mr. Cooke—You requested me to be more particular in relation to my experiment with lime in growing wheat.

The cost of lime in this vicinity is from four dollars to four dollars and a half per cask. I obtained mine by going to Weathersfield with my own team for it. It costs from a dollar and a half to two dollars per cask at the kiln, with the cask. or fifty cents less without.

My mode of applying it in compost was as follows:—Having a quantity of meadow mud, chip manure, &c., on hand, I put a layer of that three or four inches thick, then a layer of unslacked lime, of perhaps an inch in thickness, then another layer of compost, and so on alternately until my lime was all worked up. It remained in this situation a week or two, until the lime was completely slaked by the moisture of the compost, when it was shoveled over and thoroughly mixed. It was then applied to the land; ploughed in and well mixed with the soil by harrowing.

How much of the crop should be attributed to the lime, I know not, but am of opinion that enough to pay the extra expense was obtained in consequence of using it—so that if it benefits the land hereafter, it will be net gain. I am decidedly of opinion that it is better to apply it in compost than any other way. I tried various experiments with slaked lime as a top-dressing, without any apparent effect.

I have used lime but one season, and that an unpropitious one; perhaps further experiments will modify my present opinion of its utility, as well as of the best mode of applying it. In that case you may expect to hear from me again.

J. K. SMITH.

Dublin, January 1st, 1838.

SEEDLING CANTON MULBERRY TREES.

To the Editor of the Farmers' Register.

Georgetown, D. C. Sept. 1st, 1838.

I send you above, an impression from a leaf of a new variety of mulberry; it is not so large as the leaf of the *morus multicaulis;* but I think thicker and softer, and will prove, I have no doubt, a valuable acquisition. I procured last winter, through the department of state, a pound of this seed, from the consul of the United States, at Canton, China—represented by him to be the mulberry most esteemed in that country, for feeding silk-worms. I had not much confidence in it, as I had heard and seen so many statements, that good kinds of mulberries could not be propagated from seed, or that they did not follow their kind. That doctrine may be true generally; but this plant is an exception, as they are all alike, as far as I can judge—though some are very tall and thrifty, and others, where they stand very thick in the seed beds, are low and delicate. The leaf of which an impression is annexed, is from a plant about three feet high; and there are thousands in the beds as good.

They have in Northampton, Massachusetts, a variety they call the Canton mulberry, more esteemed there than even the *multicaulis.* I know not whether mine be the same; but it certainly bears a larger leaf than any mulberry I have ever seen except the *multicaulis*, and much resembles this latter in so many particulars that I think it is probably the original tree from which the *multicaulis*, by artificial means, has been produced. These seedlings have withstood the heat and drought of this scorching summer, better than any thing else in the garden. I would sell a few thousand of them. Very respectfully, your obed't. servt.

J. MASON, Jr.

[The impression of the leaf is 6⅜ by 5⅜ inches, and not lobed. We have never seen any of the Canton mulberry trees of Northampton; neither that of Dr. Stebbins (described by him at page 257 of Farmers' Register,) nor Mr. Whitmarsh's famous "Chinese mulberry" seedling; and if it were otherwise, the identity or difference could not be pronounced upon, merely by comparison with the picture sent. But the description given by Mr. Mason, seems to agree very well with that of the Canton, as given by others. The reason why the latter is preferred in Massachusetts, is not because of its superior value, but because it is more fit to withstand the rigorous climate of that region. It will scarcely be preferred in any place where the *multicaulis* will grow well and safely. Though we have no faith, in general, in the seeds of any mulberry bringing with certainty the same variety as the parent tree, we admit that Mr. Mason has good ground (in the similar appearance of all the plants,) for considering that his kind is an exception to this rule. He is mistaken in supposing that the leaves of his kind are the largest of any except the *multicaulis.* This will be evident to him on referring to a piece in a previous part of this number, (at page 417,) in which the sizes of leaves of the native mulberry, and also of sundry seedlings, are stated.—ED. FAR. REG.]

From the Franklin Farmer.

HOES.

Many of our most thrifty farmers of the east grind their hoes, and take a file to their fields with them to sharpen them when dull, with as much regularity as they take a whetstone with them to the meadow. Those who have never used a ground hoe would be astonished at the comparative ease and expedition with which he can prosecute his work with that useful little implement.

SILK CULTURE AND MULBERRY SPECULATION.

The editorial article on this subject which appears in this number, (page 389) was in type (except the closing postscript,) before the reception of the communication of Thomas Hicks, esq., which was published in the preceding number (page 378); and the first-named article was expected to have been presented, in the proper order of time, before the latter. Our absence caused the omission—and the consequent awkwardness of appearance of our notes to Mr. Hicks' letter, which were written to follow, though in fact they preceded the publication of the older article.

It has happened upon several occasions, in this work, that a communication exhibiting errors and mistakes of the writer, has served to bring forth correct and full information on the subject, from others better informed. We hope, and have now reason to expect, that such will be the fruit of our remarks on what may be termed (in more than one sense) the *mystery* of silk-culture in this country. We have been seeking, by other means, as well as by the publication of the article referred to, (and its still earlier communication in the proof sheet,) to obtain information on this interesting subject; and we are promised, and hope to receive, in part, before the appearance of this number, from two very intelligent and well-informed correspondents, interesting and valuable information on different branches of this subject.

In the time which has elapsed since the printing of the article referred to, we have heard of circumstances which, if of earlier occurrence, would have varied the details, and some of the inferences, though they serve to confirm the correctness of the general views there presented. The demand for plants of the Chinese mulberry has indeed so greatly increased at the north, that every plant and cutting now in Virginia, may be sold this year to northern purchasers at the highest prices. To our previous views and recommendations, therefore, we would add the advice to all who have plants to spare, not to sell any to speculators lower than at the highest prices; to raise as many plants as possible in 1839, from the stock retained, and to be prepared then to supply the whole country, at greatly reduced prices, and yet at greater profits than the highest prices at present would give. Every single bud planted next spring, and well taken care of, will produce from 10 to 70 buds—say not less than 30 on an average; and therefore at a half-cent, or even a quarter-cent the bud, the stock of 1839 will yield a much greater sum than the present growing stock at 2 cents the bud, or 25 or 30 cents the rooted plant. But whether the sales are made this year at the present high price, or next year at much lower, it is gratifying that the course of trade is so completely turned, and that northern purchasers are now coming to the south for supplies, and that this year more money will thus be paid to Virginia, than all that the northern nurserymen have before got from us for their immature and defective plants, with which this state was stocked.

It is not merely the rage of speculation, stimulated by legislative bounties, that has caused this great demand at the north. There is a real and great scarcity of *morus multicaulis*, caused by the immense loss of cuttings by the wet and cold weather of last winter and early spring, and the drought of summer.

The following communication to the Petersburg Intelligencer shows that our late correspondent, Mr. Hicks, of Brunswick, has already been well paid (and it was by northern purchases,) for his enterprise. Agents of sundry large dealers and speculators have already gone through lower Virginia, and have engaged (and, we fear, generally at half the price they were willing to pay,) all the plants of the *morus multicaulis* they could find for sale.

Lawrenceville, Aug. 28th, 1833.

"I think the public ought to know that Mr. Thomas Hicks, of this county, the year before last, and last year, laid out $245 in Chinese mulberry trees; and this fall will have for sale 30,000 trees. Two days ago he sold 20,000 to some gentlemen in Pennsylvania, at 25 cents a tree—the residue he reserves to sell in this vicinity; having realized the handsome sum of $7,500, from so inconsiderable an outlay, in so short a time. Mr. Hicks expects to have, by fall twelve months, 150,000 trees more for sale, and in all probability will get nearly or quite as much per tree. He has also commenced, the past season, making silk, and has succeeded beyond his expectations, demonstrating that our country is congenial to the production of that beautiful and valuable article. Mr. H. deserves the thanks, and has the congratulations, of the community, for his enterprise and success in introducing a new source of revenue and profit to the country."

Having written to Mr. Hicks to know whether this statement was entirely correct, he has stated in reply that the writer had made some mistakes, which he corrects, as follows:—"The outlay for my plants was $345 instead of $245; and the time allotted me to raise the trees is one year more than I have been employed. I never saw a Chinese mulberry tree until last year, (summer of 1837.) I think it probable I may be able to plant 200,000 cuttings next spring, instead of 150,000. The balance of the letter is all correct."—"If I had not sold the 20,000 trees, they would now bring me $1000 more than I am to receive."—This letter is dated September 8th, which was 12 days only after the sale had been made.

Since the 20th of August, the agents of at least five different and distant *multicaulis* dealers have visited this place, for the purpose of purchasing the plants which are in and near Petersburg. Most of these agents have come since the first of these lines were written. So rapid and violent has been the rise of the *multicaulis* speculation, that our monthly publication can give but a faint idea of its progress. For the last month, almost daily reports would have been necessary to show the state of the trade and the extent of the demand. Considering that the northern states are the original seat, and still the principal scene, of this speculation—the great void which still is to fill, throughout both the north and the south, for actual as well as speculative demand—the difficulty with which young *multicaulis* plants are raised in the north, and the far greater vigor in growing and after-value of those raised in Virginia—it will not be more strange than the present state of things, if very high prices should continue to be maintained through another year. But all prudent holders and planters here ought so to act as to be prepared to meet a great reduction of price. The few persons who are so fortunate as to have many growing plants, of course, will do right to make the most of the present demand for their surplus stock. But with a view to all interests, it will be better to plant next spring than to sell *abroad* now; as 8 cents. or even 6 cents the tree, in 1839, will pay a far better profit, than to sell the stock grown in 1838 for four times those prices—which may now be readily obtained. Much money must be brought into Virginia from other states by the mania for this trade; and so far and to effect a general spreading of the *multicaulis*, which this mania certainly will, it will produce much benefit to public interests. But when the violent fever shall have subsided, it is to be feared that as great a reaction (or non-action) will follow the unnatural excitement; and that the proper business and regular and good profits of silk-culture will be scorned and neglected.

From the (British) Quarterly Journal of Agriculture.

THE CULTURE OF RHUBARB.

My notice of this exquisite vegetable shall be comprised in a few lines; but these, I trust, will avail to extend its culture more and more; for any thing more productive, salubrious, profitable, and expressly suitable to the purposes of the cottager, can scarcely be found in the entire list of vegetable productions. A few years only have elapsed since the rhubartic hybrid, *green* rhubarb, was cultivated for tarts; and held in very slight estimation: but since the introduction of the larger (giant) varieties, the demand has increased with surprising rapidity. Of the two sorts which I earnestly recommended, one is called, if I mistake not, *Radford's scarlet Goliah ;* and the other is a small *red* variety which is crimson throughout when boiled or baked. These will supply the table from April to August, and suffice for every purpose.

Culture.—Let the ground be prepared precisely as for asparagus beds. Select clean offsets, with two or three bold eyes: the first week in March is a very suitable season. The eyes or buds of the Goliah will be of a deep, rich red, hence its name : the leaves, however, and stalks are green, though of different hues, and the latter are spotted and streaked with red. In the smaller pink variety the red tint prevails throughout.

The plants of the great Goliah should be set firmly in the soil, five feet apart, or five feet one way and four feet another : the smaller kind may be set three feet asunder, plant from plant, giving a free watering to each to settle the soil among the roots. Dry weather, an open condition of the ground, and a temperate unfrosty state of the air, should be preferred. When the growth becomes established, the ground must be kept free from weeds ; and if dry weather supervene, water ought to be freely given round the roots, two or three times, with intervals of four or five days.

Not a leaf or stalk ought to be touched during the first year : and in autumn, when the leaves are all decayed, they should be laid in little trenches formed along the centre of the spaces, between the rows, sprinkled with a handful or two of salt, and covered with the earth that had been dug out. Thus the plant will itself furnish a portion of the manure that will be annually required. As winter approaches, a coating of well decomposed stable manure or leaves, or a mixture of both, two or three inches deep, should be laid round each plant, to the extent of two feet ; and in the open weather of February and March, the whole bed must be forked over.

As a proof of the excessive productiveness of the *scarlet Goliah*, I need only mention, that, in the 2d week of March, 1831, twelve plants were set in ground prepared for asparagus. In June, the leaves met and the whole plot was covered. In 1832, the plants yielded profusely, many leaves measured above a yard and a half over the surface, the foot stalks being an inch and a half broad, and from two to three feet long. The outside leaves were, as required for use, stripped off by an oblique pull, not cut ; the family was amply supplied till July and August, and yet the plants increased; the neighbors also were furnished with *leaves*, throughout the summer, and with *offset plants* in the succeeding spring. During the two past seasons the root stocks increased to such a size, that when it became needful to remove some, it required a barrow to contain the weighty mass that was raised, after great labor, from the soil. If any one try the experiment in a favorable soil, and with any thing like judicious management, he will scarcely fail to discover that the growth and production of the plant will exceed every demand that can be justly made upon it.

From the Farmers' Cabinet.

ROOT CULTURE.

No crop is so important to the farmer as roots, and yet they are seldom appreciated, either as a means of enriching the soil or of supporting stock. The produce of an acre of roots with the hay that may be cut off the ground previous to sowing the crops, will feed six or seven cows during the winter season, which, with a reasonable allowance of litter, will make thirty cart loads of manure. To try this experiment, we sowed an acre of ruta baga turnips, last season, in the following manner. The ground had been laid in clover the previous season, which we mowed the 20th of June, and yielded two tons of the first quality hay. We then ploughed it down immediately and spread upon it sixty bushels of lime. In a few days we harrowed it and spread over it 30 loads of compost, which had been collected through the winter, and turned twice ; the consistency and cost of which were as follows :

2	loads of bone dust, say 50 bushels at 30 cts. . .	$15 00
2	do. ground oyster shells, 50 bushels at 10 cts. . .	5 00
2	do. leached ashes, 50 bush. 8 cts.	4 00
2	do. glue-makers' offal, .	4 00
4	do. well rotted stable manure, at $1 50, ...	6 00
18	do. shovellings from under fences and old houses, 75 cts. .	13 00
60	do. lime at 18 cts. . .	10 80
90	bushels. Total for manure	$58 30

To ploughing the ground, . . .	1 50
do. harrowing several times,	1 50
do. sowing the seed, . .	75
do. half bushel seed, . .	1 50
do. 20 days' work clearing, thinning and hoing three times through the summer, 62½ cts. . . .	12 40
do. 6 days' gathering, drawing and covering, ...	4 50
do. interest on the value of an acre of land, . . .	3 00
Cost of the crop, ...	$83 55

There were over 850 bushels of turnips at 56 lbs. to the bushel, and 4 tons of tops.—Several cart loads of the turnips were sold in the market at 16 cts. per bushel, but the principal part of these was consumed upon the farm in feeding milch cows. The hay was sold for $20 per ton, which, after allowing $6 for expenses of moving, making and taking to market, leaves for 2 tons,

	$34 00
By 850 bushels of turnips, at 16 c.	136 00
do. 4 tons tops at $2 per ton,	8 00
Total value for the produce,	$178 00
From which deduct the expense,	83 55
Leaves the net proceeds,	$94 45

The ground last spring was in a fine condition, one half of which we put in with the mangel wurtzel beet, the other part with the parsnip. The crop was put in with very little manure—the beets look in a very flourishing condition, but the parsnips are poor, they did not come up in time to make a crop.

We have this season about 4 acres of the ruta baga, but planted in a different manner; the particulars of which I will reserve for future.

A COMMUNICATION.

Wilmington, Del., 8 *mo.* 20, 1836.

From the Genesee Farmer.

SQUASHES TURNING TO PUMPKINS.

Mr. Buckingham, the able editor of the Boston Courier, appears to appreciate the importance of the agricultural interest to the prosperity of the country, and devotes a column or two of his journal weekly to the dissemination of information on this topic. Besides evincing much skill in his selections, he gives some original papers of value. In a late number of his paper is a communication signed 'Ruricola,' who requests an explanation of the fact that squashes do sometimes change to pumpkins, or rather that squash seeds will when planted produce pumpkins. Ruricola selected his squash himself, took out the seeds, and planted them; they grew freely, and when he was expecting a feast of this excellent viand, he found they had been metamorphosed into pumpkins. Ruricola asks if this is any thing new under the sun? and requests Mr. Buckingham to explain "this singular freak of nature."

Mr. Buckingham in reply makes in part the following remarks:—"We would observe, however, that it is not an unvarying law of the vegetable kingdom, that like ever does, and ever will produce the like. It is a well known fact, that the seed of apples, pears, peaches, and other fruits, seldom, (perhaps not once in a hundred times,) produce fruit like that of the parent tree. But perhaps our correspondent will say that these are not parallel cases, and to make them so, we should cite one in which the seed of an apple should produce a pear, or that of the peach a plum. We will not attempt to remove this difficulty. It is beyond the reach of our knowledge. And we submit it to those whose better experience, and deeper research into the mysterious laws of vegetation qualify them to unravel and explain the same."

Without any pretension to 'better experience' or 'deeper research' than Ruricola or Mr. Buckingham, we think the matter can be explained very easily; and we give what we conceive such explanation, the more readily, as the transmutation of squashes into pumpkins, a well known fact, has by many been considered a proof that wheat could be changed to chess, an event which we think never has been, and probably never will be, proved.

To make the matter plain we may remark that botanists divide all plants into species, and these into varieties. Of the species we may give as examples the cucumber, *(cucumis,)* and the squash, *(cucurbitis.)* Of the first there are several varieties, as is known to every gardener, and that these varieties will intermix by the seed is also well understood. The squash is another species of plant, with numerous varieties also, among which we may enumerate the *lagenaria*, or gourd; the *ovifera*, or egg squash; the *verrucosa*, or club squash; the *citrullus*, or water-melon; and the *pepo*, or pumpkin. The musk-melon belongs to the *cucumis*, or family of cucumbers.

Now it is well known to the naturalist that while *varieties* will intermix by their seeds, a result caused by the impregnation being performed by pollen from another variety of the same species, *species* never do this; but that while all the varieties of the squash, if planted in the vicinity of each other, are liable to have their seeds affected in this way, so that no certainty can be placed on their producing plants precisely like the parent, there is no danger of change in the cucumber or musk-melon from being planted in the vicinity of any variety of the squash. In the varieties of the squash, therefore, great care is necessary to keep the kinds distinct, or prevent, in the way assigned, their intermixing with and degenerating each other. The probability is, that the squash from which Ruricola took his seed was impregnated by pollen from the flowers of pumpkins in the vicinity, and hence the fruit was of course a hybrid, or one in which the pumpkin nearly or entirely predominated. To preserve seed like the parent plant, in the squash or cucumber species, it is found best to save the fruit that grows nearest the root; as in this case the male and female flowers, or those that produce fruit and those that do not, are brought into immediate contact, and the impregnation more likely to be performed with pollen from the same plant, than with that from abroad. Thus we see that the changing of squashes to pumpkins, or vice versa, belongs to the natural order of events, and is nothing new under the sun.

The same rules that regulate the impregnation and production of the cucumis and cucurbitis, will apply to the plants *triticum* and *bromus*, or wheat and chess. Experience shows that an endless variety of shades can be produced by sowing different varieties of wheat in the same field, or so that the pollen can intermix freely with the different flowers, the product however as we believe being some variety of wheat, and never chess or any of its varieties. We have never met with any evidence that the musk-melon has changed to the water-melon, or the cocoanut squash to the cucumber, though frequently planted in the vicinity of each other; the changes are confined to the varieties, and rarely or never reach the species. The remark, therefore, of Mr. Buckingham, that in the vegetable kingdom like does not always produce like, is correct if restricted to varieties, but incorrect if extended to species.

From the New England Farmer.

THE QUEEN BEE.

Having read some of the various theories on the honey bee and compared what I read with my own observation on the bees themselves, I have become satisfied, that notwithstanding so much has been written, very little is known of the government, police, or interior arrangements of the inmates of a bee-hive.

Writers informs us that a "*swarm of bees contains one queen, five hundred drones and nineteen thousand four hundred and ninety-nine neuters.*" Who knows any thing about this? Could we at pleasure examine the inside of an inhabited hive and closely watch the movements therein, we might form some opinions as to this army of neuters marshalled by a queen and drones, but human ingenuity can devise no way in which this can be done with any degree of exactness; we can only look around us and see how it is with other insects and animals that can be examined with impunity. Where throughout animated nature can we find a parallel? Does nature usually form neuters, or are bees an exception?

But neuters are not my object in this communication. I am even so much of an infidel as to doubt the existence of a queen bee. My doubts are caused in part by the following circumstances. I have carefully examined several swarms of bees after suffocating them with fire and brimstone, without being able to find *her majesty of "about eight lines and one-half in length, her wings so short as scarcely to reach past the third ring, and her color a deep yellow.* The present season, one of my hives swarmed and settled on the limb of a young apple tree near the ground. In a few minutes after, another hive swarmed and collected on the same limb nearer its end, leaving a space of about two inches between the swarms. The additional weight of the last swarm brought the limb so near, that the winds swung it against the ground so as to incommode the last comers. They began to gather up the limb nearer the first swarm and finally formed one cluster of bees, which I put into a flour barrel. They commenced working, and have now every appearance of prosperity. In this case where were the two queens who "*are infused with the most deadly hatred and the most insatiable thirst for each other's life, which nothing but actual death can appease?*" About sunset on the sixth of the present month I accidentally noticed a great stir amongst my bees, and on examination found a constant passing and repassing between an old hive and a late swarm from the same old hive, standing some eight or ten rods apart. The following morning at daylight the same intercourse was continued. The bees passed by thousands, and both hives appeared alive with bees. Although very anxious to find out what they were about, yet as there was every appearance of perfect harmony in their proceedings, be they what they might, I left them to settle their *own business in their own way*, and on my return after an absence of two days found that the old swarm had abandoned their hive to the bee moth and gone to reside with their children, having removed every particle of honey to their new habitation, leaving comb, bee bread, and moths in the old hive. Where were "the rival queens, who always lead the swarms, and cannot dwell in the same hive?"

In what age of the world the discovery was made that a hive of bees contained but one female and that one *the ruler of the swarm*, is unknown, probably when a great taste for the marvellous was in fashion, and Huber and subsequent writers could adopt a plausible theory with much greater safety than to thrust their heads into a bee-hive and watch the bees for some days.

J. B. T.

August 18, 1838.

THE PEACH TREE.

From a desire to encourage the culture of the peach tree, we offer the following as the result of experiment and observation.

It is generally known that worms, near the surface of the earth, destroyed them by eating the bark; the object is, therefore, to find a preventive, in order that the trees may become aged in a healthy state.

It is evident that these worms pass through the common change and assume the form of *millers*, early in the summer, and deposit their eggs on the bark as low as they can find access to it; and that the worms proceeding from them begin to operate in the latter part of the summer, when they have been found the size of a common pin. If suffered to remain they grow to the thickness of a rye straw; each of them girdles the tree about an inch, and the wood from the wounds to the heart dies. Hence it is, that a single wound impairs the vigor of the tree and a number of them will kill it. The point to be gained, is to protect the tree from the millers, and by a simple method, we have succeeded for several years, which is recommended with full confidence.

About the first of May remove the earth from the body of the tree, and shift it to the height of 15 or 16 inches, in such manner as to exclude the millers, burying the lower part of it in the earth. We have used straw cut to the length and about half an inch in thickness, bound on with twine. This should be removed about the first of September, as we have sometimes found the young worms in the upper part of the straw, being then readily discovered on the surface of the bark, covered by a little gum. The process should be commenced when the tree is young—they have been found n a rapid growth the first fall after it sprouted. Thus a few minutes in a year devoted to a tree will protect it against this cause of decay—a very trifling expense compared with the value of this healthy and delicious fruit.

Hartford, Conn. Sep. 8, 1830.—*Conn. Paper of 1830.*

For the Farmers' Register.

TREATISE ON THE CULTURE OF SILK.*

BY GIDEON B. SMITH.

NO. I.

Prefatory Remarks.

The introduction of the culture of silk in the United States has been an object of great interest for some years past, and has been steadily on the increase, until it has now become almost, if not quite, a mania. In 1826, a silk-worm was a curiosity in most of the states of the union; and but little was known or said about it. At that time the writer of these remarks commenced calling public attention to the subject, and for seven years kept a laboratory expressly for the purpose of obtaining and diffusing information. He had access to all the books then extant on the subject, but they afforded little practical information. Every thing was new to him, and every thing consequently was to be learned from experiment. Happily, the simplicity of the whole routine was such, that careful observation and diligence enabled him to acquire the information he sought without material difficulty. From time to time he has published the result of his experience, on the subject generally, and on particular branches; but as the public feeling has now become more generally enlisted in its favor, the demand for information has increased. The writer is almost daily applied to for his opinions and the result of his experience. He has therefore determined to publish the following treatise.

The subject conveniently divides itself into three parts, viz.: The *culture of the mulberry*, *rearing the silk-worm*, and *reeling, twisting, and preparation of raw silk.* And these three divisions can conveniently be discussed in three numbers of the Farmers' Register. The following pages complete the first part, *the culture of the mulberry*, and it is hoped with sufficient clearness to enable any one to understand the subject distinctly. On the whole subject we shall endeavor to avoid disputations, entering into no critical discussions or controversies on disputed points; but giving our own opinions freely. If we describe one practice and say nothing of another, it is because we know the one to be the right one, and therefore say nothing of the other; for why should we take up our own and the reader's time in describing that which we know to be useless? With these introductory remarks we submit the first number to the public.

The Mulberry, Multicaulis Culture, &c.

The first thing to be done in the commencement of the culture of silk, is, of course, to provide a full supply of mulberry leaves. The leaves must be abundant, that no stinting of the worms may occur from any cause, at a moment when the whole crop depends upon a full and ample supply of food, which is during the last ten days of their feeding. The mulberry orchard must be convenient to the laboratory, that the expense of attendants for gathering leaves may be as small as possible. There are many accidents that may cause the loss of leaves; during rainy weather it is necessary to gather a supply for a few days ahead, that they may be dried before feeding them to the worms;* these may become spoiled, and thus lost. Therefore we should generally make provision for double the quantity of leaves that we expect to consume; for if we lose none, the cost of this extra provision will be trifling, compared to that of a whole crop of worms, from a deficiency. This is the only mode by which we can effect an *insurance* against such loss.

The kind of mulberry to be employed, is the next object of attention. When I published my 'Treatise on the Culture of Silk' in 1830, I had very little experience with the new Chinese variety, the morus multicaulis. It had at that time been but three or four years in the country, was not known at all except to very few individuals, and had of course not been propagated to any extent. It is true, I had the tree in my possession, and knew its value from a brief experiment in 1828 and 1829; but my supply of leaves from it

---

* This new treatise, furnished from a source of such high authority, would, under any circumstances, constitute a very valuable portion of the original matter of the Farmers' Register; but more especially interesting, and useful for practical instruction, will it be at this particular juncture, when so many persons, who are totally unacquainted with the business, are about to commence the planting of the Chinese mulberry tree, and expect to commence the rearing of silk-worms. To supply the manifest want of such a manual of instruction as could be relied on for truth, and sound views, from a writer having much practical experience, as well as knowledge of all that has been published in this country on the subject, was the object which induced our request to Mr. Smith to write a treatise on silk-culture, as much in detail as his arduous engagements would permit him to prepare. This first number of the proposed series, is the commencement of his fulfilment of our request.—ED. FAR. REG.

* I have seen with much surprise a statement in the newspapers that a gentleman had made experiments in feeding silk-worms with wet leaves, and that the result was very favorable, the cocoons made by worms thus fed containing 800 yards of fibre, &c. If the statement be not a hoax, and one calculated and intended to do injury, by causing the destruction of whole crops of silk-worms, it must have been founded upon a very insufficient scale to test its merits. I have seen the evil not only of feeding with wet leaves, but even with leaves too succulent. I would therefore caution silk-growers against such statements; and advise, that, if they wish to try the experiment of feeding with wet leaves, to do so with a single hurdle, and not risk the loss of the whole crop; for be it known that the *tripes*, the disease usually produced by wet leaves, will generally spread over and destroy all the worms in the largest establishment, in a very few hours from its first appearance.

was necessarily very limited, and though I was satisfied of its superiority as food for silk worms, I was not prepared by sufficient practice and observation of its character, to say that it was capable of supplying the place of the white mulberry. I was not sure that it was sufficiently hardy; nor, even if every way preferable to the white, that a supply could be obtained sufficient for this extensive country. I therefore said nothing about it in that treatise, but gave the white mulberry the preference. After the publication of my treatise, however, in 1830, I satisfied myself of the superiority of the multicaulis over every other variety in every point. I found that it could be propagated more rapidly than any other tree, by cuttings and layers, that it furnished a supply of leaves in one-fourth the time required by the white mulberry, and therefore could be made to make returns for capital invested in it so much sooner; that a pound of its leaves contained as much nutritive matter as a pound and a quarter of the white mulberry; that the expense and trouble of gathering the leaves was not one-tenth as great as those attending the white; that the worms consume the whole leaf, thus leaving the hurdles less encumbered with the refuse; that the silk made from it was of a very superior quality, in strength and lustre; and finally that the worms in all cases gave it the preference over all other kinds. In my experiments I had the advantage of using fifteen different kinds of mulberry, and have often placed leaves from all of them together upon the hurdles; and the silk-worms invariably seized upon and consumed the morus multicaulis first. Up to the present time I have found no reason to change my opinion of the valuable qualities of this tree in any of the above particulars; on the contrary, every year has confirmed it.

One point of comparison between the morus multicaulis and other varieties I have reserved for separate discussion; not from any doubt remaining in my mind, but from its importance, viz., its *hardiness*, or capacity for resisting the effects of our severe winters. I have now had ten years' experience, and have had the tree exposed to all the severities of the last ten winters, (near Baltimore,) and have never yet lost a tree, nor the limb of a tree of the morus multicaulis, from winter killing. Fortunately, the situations where I first planted my trees were high and dry, and the soil composed of sandy loam. The trees throve remarkably well there, grew early in the season, ripened their wood early in autumn, and withstood the inclemencies of the winter, without a bud perishing. But some of my friends to whom I had given trees, and who planted them in rich low-ground, lost them entirely, or had the tops killed to the ground; and this fact led me to the conclusion, that high, dry, sandy, or loamy soils, were the proper situations for them; and all my future experience has confirmed me in it. All who formerly lost their trees in winter, and have removed them to high situations, have experienced the benefit of the change. The conclusion is, that the morus multicaulis is a *high-land tree*, and when cultivated on high grounds it is perfectly hardy, and capable of withstanding our winters, as much so as any of our native trees. During the winter of 1831–2, my old tree, (the first one that ever came to the United States, and which I yet possess,) was removed to the premises of a friend for safe keeping, (as I was removing to a farm in the country, and not knowing how long I might remain,) and was exposed to all the severities of that most inclement winter. I felt sure that it must have been killed, if not by the winter generally, certainly by that most terrible visitation of frost on the 17th and 18th of March, 1832. But to my surprise and great pleasure it did not lose a bud on that occasion. What is very singular, there was a white mulberry tree standing within 50 feet of it, six or seven years old, that was killed entirely by the winter. Both were equally exposed. I do not intend to infer from this, that the morus multicaulis was more hardy than the white; nor can I account for the death of the latter; the fact however was before my eyes. The trunk of the white mulberry, which was about three inches diameter, was split to the heart from the ground to the limbs. This old multicaulis tree was again removed to its present site in my garden, in the autumn of 1835, and of course now receives considerable protection from the house on the north, and high fences on the other sides. It makes generally young wood from 6 to 8 feet high every year, and the leaves on the young wood are generally 12 to 14 inches long, and 11 to 13 wide. Besides this old tree I have always had others in various situations. Those I had on the farm in 1831, '32, were planted on a hill, perfectly exposed to the north-west blast. The farm is at an elevation of 3 to 400 feet above tide. They withstood the effects of the winter perfectly. From all these considerations and facts, I think I am authorized in pronouncing the multicaulis perfectly hardy, when cultivated on high ground—its proper situation. But it is said that the multicaulis is not generally adopted in France and Italy in the silk establishments; and therefore there must be some fault in it. Some say it does not live long—soon decays—the silk made from it is weak and of a flimsy quality. All of which I know, from my own experience and the experience of all who have given it a trial, to be incorrect. That it is not generally adopted in France and Italy is easily accounted for. The demand for trees has always been so great that it was found more profitable to sell them than to keep them to feed silk-worms with; as they could get more money for one young tree than a dozen would produce in silk. They have also their ancient prejudices to contend with, and their ancient customs to combat in France and Italy. There the mulberry trees are owned by land-holders, and the leaves are sold to the raisers of silk-worms by weight. These land-holders have their old white mulberry trees on their estates, and they of course will be compelled to get rid of them before they adopt the multicaulis. These facts render it quite probable that the multicaulis is not generally adopted there; it would be a wonder if it were; for it is not often that we find any people, French, Italian, or American, willing to manufacture an article, worth when made only a penny, from materials that he can sell for a shilling. And it is the same in the United States. How many societies have been incorporated for the culture of silk, and how many individuals have commenced plantations of trees for the same purpose? And yet where is the silk they have produced? We, it is true, occasionally hear of this, and that person having produced his hundred bushels of cocoons;

and of this and that fine specimen of silk; but generally these silk societies and individuals have found they could raise and *sell* trees to more profit than they could realize from feeding silk-worms, and they have generally adopted that course. This will do no injury to the public, for soon the whole country will be supplied with the trees, and then both societies and individuals will fall back to their original object, the culture of silk.

Description of the Multicaulis.

The morus multicaulis is a dwarf tree, or more properly a large shrub, with *many stalks*, as its specific name implies, growing like the hazel, lilac, &c. It is continually sending up young shoots from the crown of the root, and when these become numerous, and the tree 6 or 8 years old, some of the oldest stalks die out; but whether from natural decay or being perished by their vigorous young brethren, I am unable to say. My old tree has been as high as 15 feet, 6 or 7 feet of which was young wood; but as I generally cut off most of the young wood for propagation, it has never exceeded that height. The leaves when full grown on the vigorous wood are 12 to 15 inches in length and 10 to 13 inches wide. The rapidity of their growth causes the ribs to grow faster than the *web* of the leaf, and hence the large leaves, are always *concave*, so that they cannot be spread out flat without tearing them from the edges to the mid-rib. The leaves are so heavy that they always hang, penduleus, and folded somewhat like a towel hung upon a nail. The surface of the leaf has a somewhat glossy appearance on the outer surface, but is a little rough to the touch. The fruit of the multicaulis is very black when ripe, and when crushed yields an intense purple juice, the stain of which is exceedingly difficult to wash out. The fruit is about the size and form of the white mulberry, but generally contains very little good seed—probably my old tree never produced more than 20 at one season.

It is a remarkable fact that all the species and varieties of mulberry tree are exempt from the depredations of all insects except the silk-worm. During ten years that I have been a close and daily observer of the morus multicaulis particularly, I never saw an insect of any kind upon it. The common caterpillar seems to be omnivorous—with the exception of the mulberry only—it never attacks that. The elm a few years ago was considered exempt; but it also is now annually stripped of its foliage by insects; and the *linden* also suffers more or less, but the mulberry remains untouched. Even the grasshoppers of the present year, 1838, more destructive than they were ever before known to be, pass by the mulberry, seemingly in acknowledgment of the great law of nature which devotes it as food for the silk-worm exclusively.* On the other hand there is *no other* vegetable that I ever was able to make the silk-worm eat as food. I have starved them, it is true, till they would eat lettuce; and ultimately till they would nibble at oak leaves; but they ate them and all other substitutes, as human beings, in a state of starvation, eat old shoe leather, not as their proper food, but in the hope of sustaining nature a few moments longer. The *Osage orange, Maclura*, is an exception. They eat that freely; but it is so like a mulberry in all its characters, that it required considerable ingenuity in the naturalists to call it by another name.

Having given my preference for the multicaulis, over all other kinds, and my reasons for it, it will not be expected of me to say any thing of other kinds; for, if the reader puts confidence in what is here written, he will adopt the multicaulis without inquiring about other kinds; and if he do not thus confide in my statements, any thing I could say about other kinds would be of no avail.

The mode of cultivating the multicaulis, is the next subject for consideration. The simplest and most common plan is as follows. Prepare the ground in the spring as for corn. Run furrows four or five feet apart, as preparatory to planting corn. Then take the limbs and young wood that grew last year, cut off close to the tree, and lay them lengthwise in the furrow; the but-end of one limb a short distance, a foot or so, from the top-end of the last laid down; cover the whole limb, with a hoe, about one or two inches deep; generally every bud on each limb will grow, and make a tree 3 to 5 feet high by autumn. The ground should be kept free from weeds and grass, by cultivation, as in corn. About the last of July, it is best to take a sharp spade and separate the young trees, by driving it down midway between them; but this is not essential; they can be separated when taken up the spring following. The next spring they should be taken up and planted in regular form in the orchard, where they are permanently to remain. The best method is to plant them 6 or 8 feet apart in the row, and the rows 10 to 15 feet apart—the rows running north and south, or north-west and south-east. By this mode of cultivation it will be perceived that eight or ten times as many multicaulis trees may be raised on an acre of ground as of *corn-hills*, and that, as the crop is ready for the market, (when they are raised to sell) as early as a crop of corn, there is no reason for the extravagant prices demanded for them. They would be a very profitable crop at 5 cents a tree.

There are other modes of cultivation which it may be well to describe here. Where cuttings are scarce, and the loss of any of them is of much consideration, a hot-bed should be made in the usual way, and the cuttings started in it as follows: Cut all the limbs and young wood into short pieces, with *one bud* on each; lay them flat on the surface of the hot-bed, in lines lengthwise, the ends of the cuttings a quarter of an inch apart, and the lines of cuttings two inches apart, with the bud uppermost. Then sift rich garden mould over them, half an inch deep, and put the glass frames on the beds. Every night and morning water them with a watering-pot, merely enough to keep the earth moist. They should be planted in the hot-bed one month before the usual disappearance of frost. In and around Baltimore, about the 1st of April is the time, as frost usually

* The fact stated in the text is without doubt very *generally* true, but not *universally*. Within a few days, we have seen several young multicaulis trees, partly stripped of their leaves by broods of caterpillars, which had spread their webs over the part of the plant of which the leaves were already devoured, and whose depredations were in full progress, when they were discovered and killed.—ED. FAR. REG.

disappears altogether, about the 1st to the 10th of May. By the time the frost disappears the young plants will be about the size of cabbage plants, and may be taken out of the bed and planted in the orchard where they are permanently to grow. During the time they are in hot-beds, care should be taken in warm days to give them air, by raising the glass frames; and if severe frosts occur, to cover the glasses with straw, or matting; and when set out in the field they should be well watered for a few days, in the evening. The practice of propagating as above from single buds was first adopted by me, and followed for many years to very great advantage; and I am not sure but that it is still the best, as it often occurs that a cold backward spring rots a great portion of the cuttings planted in cold ground as first recommended above. Besides, in the hot-bed single-bud system, the trees get a month the start and make larger and finer trees. But in very extensive plantations it is "*too troublesome.*" A convenient hot-bed may be formed by those who are not provided with frames, &c., and are not acquainted with forcing gardens, as follows: Dig a pit two feet deep, four feet wide, and ten to twenty feet long, or as long as you please, if you have manure enough. Fill it with fresh horse dung six inches to a foot above the top. When you perceive it getting hot and settling down, cover it with six inches of rich garden mould, and rake it level and smooth. Let it remain for two or three days, till the heat begins to decline, and then put in the cuttings as above. At night, when cold, lay some light brush over the bed, and spread straw or mats over them, and water them as in the regular hot-bed. This method will generally be found to answer all the purposes of a perfect hot-bed.

Another method is by layers. Instead of cutting off the limbs and tops, bend the whole tree down to the ground, and cover it, limbs and all, two or three inches deep, with good mould—it would be well to turn up the ends of the limbs, so that the points are just above ground. All the buds on the whole tree that are under ground, will generally grow and each one make a tree by the autumn, when they are to be taken up and separated. The objection to this plan is, that the young trees are apt to be too crowded, and consequently do not grow as large as when the limbs and young wood are cut off, as in the first mode; and I do not find that it is any more certain, or possesses any one advantage over that mode. All other modes of propagation, grafting &c., are perfectly useless, and therefore nothing need be said about them.

It seems, however, proper to remark, in explanation of the omission to give the mode of raising the multicaulis from seed, that this tree produces seed very scantily. Probably an acre of trees of full growth would not produce an ounce of good seed. It is generally the case with all plants that are readily propagated by other means, that they do not produce much, if any seed. But though the multicaulis were to produce seed as abundantly as the white or any other variety, its propagation by cuttings would still be the most eligible mode. The mulberry seed lies a long time in the ground before it vegetates, generally 5 to 8 weeks, and in the mean time the weeds get the start, and smother the young plants as fast as they appear, unless the most untiring vigilance and care be observed in keeping the beds clean. Even then, in spite of care and industry, many—a great proportion—of the little plants will be destroyed in the process of weeding. Even after you have raised the plants above the influence of weeds, they are tardy of growth, and do not produce leaves of full size till they have been repropagated by cuttings, layers, &c., for three or four years. All idea of raising them from seed will be abandoned by every one as soon as they become acquainted with the facility with which they are propagated by cuttings, the scantiness of seed produced by them, and the difficulty of raising them from seed.

I cannot omit the present opportunity of again cautioning the people of this country against the impositions that have been for several years practised, and are yet continued, of *selling morus multicaulis seed.* No such seed ever has or probably ever will be for sale here or elsewhere; and those who pretend to sell it are imposing upon the public a worthless article. The tree does not bear seed enough to pay for the trouble of saving it, even if it sold for its weight in gold. That the seed will produce the genuine multicaulis, I have no doubt, but it will require some years of successive propagation by cuttings to develop its peculiar characters, large leaves, &c. But this question is a matter of little moment, as no person will resort to seed when they can obtain cuttings.

The soil, situation, &c., best adapted to the morus multicaulis, have already been mentioned in a previous part of this paper. The soil should be such as will yield a fair crop of corn; if made richer, the trees will grow larger, but the advantage will not compensate the extra expense. It should be sandy loam, if possible; but gravelly or stony soil answers well: heavy clay soils do not do so well. The situation *must be high land*—that is, it must not be low bottom land. Hill-sides are best; the tops of hills next; level lands are good, provided they are eight or ten feet above the streams of water, and not subject to water standing on them after heavy rains; but if they are surrounded by hills they will not do, being more subject to early and late frosts than if not thus surrounded by hills. It must be borne in mind, that we are discussing the subject of soils and situations best adapted for the permanent occupation of the multicaulis. Where the trees are raised to sell, or to be removed in autumn, then rich alluvial or loamy bottom land is best. The trees will grow larger there; and as there is to be no risk of winter-killing, there is no other objection. In cold seasons, however, and especially in cold late springs, bottom lands are too cold for them, and consequently the trees will be small. In all cases when they are grown on bottom lands, they should be taken up in the month of November, and *buried* root and branch on some high dry situation, covering them about one foot deep. This will preserve them effectually till spring, when they should be planted out, as above directed, in a proper soil and situation. Cuttings are preserved in the same way: cut them off close to the tree in November, dig a pit two feet deep in a high situation, put them into it, mingling earth among them, and finally cover them up a foot deep at least; filling the pit entirely, and arching it as in burying potatoes, &c. Those who fear the loss of the cuttings if left remaining on the trees, can certainly save them in this way; but if trees are in proper situations there is no danger of the cuttings being killed; unless indeed from late planting in the spring, or some other cause, the wood of the cuttings has not been properly ripened. In that case, all the unripe wood will of course be killed by winter if left on the tree, and it will be proper to take the cuttings off and bury them as above.

Much has been said about making *hedges* of the morus multicaulis. As a barrier against cattle or other stock it will not do. Cattle are very fond of it, and will eat the leaves and even branches as large as the finger of the young wood. It may be used as an ornamental hedge, however, and planted in hedge form in fields, to great advantage. The distance between the rows or hedges in the latter case may be from 12 to 20 feet; the latter will admit the passage of a cart for conveying leaves to the laboratory.

In conclusion, I believe I have said every thing that need be said on the subject of the mulberry, its culture, &c. In the next number we shall discuss the rearing of silk-worms, the laboratory, &c.

STRICTURES AND REMARKS UPON FORMER ARTICLES.

To the Editor of the Farmers' Register.

Sept. 6th, 1838.

As marvellous assertions, and alleged discoveries, if published in our agricultural papers, without comment, may often lead the sanguine and inexperienced of our brethren into serious errors, it seems to me that they should always be noticed. This remark has been suggested by two articles in your highly useful journal; one in the August No. (p. 269), and dated Houston county, Georgia, which you have copied from the 'Southern Agriculturist.' The other in the Sept. No. copied from the 'Watertown Standard,' a New York paper, which appears to be editorial. The Georgia planter, speaking of the treatment of their negroes, says, (I give his own words,) "*they have their weekly allowance each, of three hundred pounds of bacon, or its equivalent, and as much hominy or corn-flour as they can consume, ground at the mills, delivered to them. When potatoes and peas are in season, they are permitted to use all they may want.*" Now this must either have been a great, but unnoticed slip of his pen, or he must be a near relation of the celebrated Baron Munchausen. Counting seven days to the week, this allowance is just forty-two pounds and six-sevenths per day, which, to say nothing of their hominy, corn-flour, peas and potatoes, ought to have enabled his negroes, instead of merely doubling Mr. Frost's cotton crop of four thousand pounds to the hand, as he states they did, to have made at least three hundred times as much.

The second article which I beg leave to notice, is published to prove the wonderful efficiency of soaking seed-corn in a solution of saltpetre. This, the editors pronounce to be "*one of the greatest discoveries of modern times in the neglected science of agriculture.*" On examination, however, of this highly interesting assertion, we find nothing whatever in their statement to support it, but merely *their* own belief produced by one single inspection of an experiment made by a Mr. Massey, who planted five rows of corn, the seed of which had been previously soaked in a solution of saltpetre, (it is not said whether or not it was a saturated solution,) while the adjacent rows had not been soaked. These disseminators of useful facts in husbandry proceed to affirm, without any apparent doubt in regard to the accuracy of their own judgment, that "*the five rows planted with corn prepared with saltpetre, will yield more than twenty-five rows planted without the preparation.*" That these gentlemen believed what they said to be true, I will not permit myself to doubt; but before any general credence can be given to such an assertion, a well authenticated statement of actual measurement must be exhibited. It certainly may be imagined as a possible thing in this age of almost incredible inventions; but a five-fold increase of crop, from so simple and cheap a process, approaches too near the miraculous, to be generally taken for any thing more than the extravagant opinion of persons of very little experience in such matters, and one, therefore, but illy calculated to induce practical corn-planters to repeat the experiment.

A word or two now, as to what these gentlemen call "*one of the greatest discoveries of modern times.*" Almost from my earliest recollection, and that reaches back more than half a century, I have known the soaking of seed-corn in a solution of saltpetre to be practised. Indeed, it was once common in some parts of Virginia; but that was at a time when I paid little attention to such matters, and therefore I do not recollect how far it succeeded. The fact however is, that the practice has long been discontinued among us, and consequently it is a fair inference that the increase, if any, of the corn crop by this process, could not have been generally thought to be even double, or we should still find the saltpetre solution in general use. So much for this asserted discovery. But since the constitutions of mankind often undergo such changes, that food, which does little or no good at one time, may fatten at another, the same may happen to the constitution of plants. Many still more extraordinary analogies have been actually traced out, or imagined to exist between the animal and vegetable kingdoms. By all means, therefore, let us all feed our seed-corn next spring, with saltpetre and water, for it is not quite impossible that we may equal or beat Mr. Massey's five rows so marvellously fattened upon that food. I, for one, am determined to try the experiment should my life be spared; and you shall have, not my opinion merely, but an accurate statement of the quantity, by measure, of the corn fattened upon saltpetre and water, and that which I shall leave to seek its food from the ordinary sources of supply. In this determination I assure you that I am perfectly serious, for I have been a corn-soaker for many years, in full faith of its efficacy to an extent which renders the practice well worth continuing. My solution, however, now very common in Virginia, has heretofore been nothing more than tar and water, in the proportion of about one pint of tar to ten or fifteen gallons of water, after which the seed-corn has as much plaster of Paris or lime mixed with it as will adhere to each grain. This protects it, in a considerable degree, from moles and birds, and probably benefits the subsequent growth and product, although I know of no experiments yet made to ascertain whether this supposition be correct or not. I remain, dear sir,

Your old friend and fellow laborer,

J. M. G.

[The article respecting the wonderful (and, as we fully concur in pronouncing, the incredible) increase in corn, from merely soaking the seed in a solution of nitre, is justly obnoxious to our correspondent's strictures. It was inserted during our absence, or it would have been accompanied by remarks, showing that the article was selected as a scrap of agricultural news, and as furnishing subject for experiment, but not as ground for belief, or confidence, upon merely the present statement. We can scarcely suppose that the editor of the paper from which the article was copied, and his friend the farmer, both being named and known witnesses, could have deliberately combined to tell so monstrous a lie, as a severe judgment *may* pronounce upon the statement made, viz., that simply soaking the seed-corn in saltpetre-water, increased the crop fully 400 per cent. We infer, that there *was* an increase, (greatly exaggerated perhaps by the guessers,) but that it was owing to some indirect benefit, and in a manner not stated, and not amounting to any noticeable addition to the fertility or producing power of the soil.

So far we agree with our friend J. M. G.; but not so in his harsh strictures upon the words of another selected article. It is very true, that the phrase quoted is not grammatically or critically correct; and, if subjected to be construed literally, and according to the strict rules of composition, that it would (if the contrary were not evident,) bear the meaning that our correspondent charges to have been conveyed. But the manifest absurdity of a man's weekly allowance being 300 pounds of meat, ought alone to be enough to acquit the writer of any intention of making such a statement. To our reading and understanding, it was so plain that the writer meant a *weekly proportion* of 300 pounds of bacon allowed for the year, that it was not thought necessary to add any editorial note in explanation. If such an inaccurate mode of expression had been seen in a manuscript communication, it would certainly have been our duty, as it is our usage, to correct it; but it is not our practice, nor would it be justifiable, to alter the text of articles selected from other publications.—Ed. Far. Reg.]

PROFIT FROM CLOVER. THE DROUGHT. SEA-ORE AND SALT. COULTERING NEW GROUND. IMPROVEMENT OF LAND AND HEALTH, &c.

To the Editor of the Farmers' Register.

Old Point Comfort, Elizabeth-city County, September 10, 1838.

The wheat crops in this neighborhood have not realized the sanguine expectations entertained before harvest. The growth of straw, was most luxuriant; but the heads small, and generally light. The fallowed wheat was infinitely superior to that sown on corn-land. I sowed 45 bushels in a field of 42 acres, 12 of which had been in clover turned in in September. The exact yield I have not ascertained, as I have got out yet but three stacks, averaging 80 bushels each; but I obtained ten stacks, and of these, four and a half were cut from the twelve acres. It is proper to state that the fallowed land was naturally the best part of the field, and would, under any circumstances, have produced the best crop; but nothing like their difference would have resulted, without the aid of the clover. A gentleman in this neighborhood, of great accuracy in such matters, told me, that last year his fallowed land yielded 26 bushels, and his corn land 13 to the acre, just one-half; and that this year the difference was full as great, if not greater; the land in both instances of equal quality. Can there be a stronger argument than this, to exhibit the benefit to be derived from clover, to say nothing of the excellent pasturage it affords for two or three months, if, like myself, you are compelled, occasionally, to turn your stock upon it, until the harvest fields are ready for them.

But, says one, my land will not produce clover, and what am I to do then? Why marl it. I don't believe there is an acre of land below tidewater, that will produce any thing, that cannot be made to produce clover. Lime it, and if you have not the means to buy the lime or marl, sell one-half of your land, and apply the proceeds to the other, and with a light top-dressing of vegetable manure, my life upon it, you will make the clover grow. I have tried it, and know it to be true. Four years ago I sowed a field in wheat, and the following spring put it in clover, at the rate of a gallon to the acre. The wheat was indifferent; the clover seed thrown away: for, except here and there in small spots, not a leaf was to be seen. The following winter I dressed this field from a deposit of burned shells, which had been on the farm from time immemorial, at the rate of about 100 bushels to the acre, and gave it a light coat of vegetable manure. In the spring it was planted in corn and yielded several bushels to the acre. In the fall it was again put in wheat, and clover sown on it in the spring: and this year I had as luxuriant and well-set a crop of clover, as I ever saw in Virginia.

We have suffered this year from the drought and heat, equally with most other parts of the country. We had no rain from the 21st July, to the 14th of August. It may not be uninteresting here, to give a comparative statement of the mean temperature, and the amount of rain that fell in the last three months and the corresponding month of last year.

1838.	Mean temperature.	Inches of rain.	1837.	Mean temperature.	Inches of rain.
June.	76	$4\frac{5}{10}$	June.	75	$3\frac{5}{10}$
July.	83	$2\frac{4}{10}$	July.	79	2
Aug.	82	$1\frac{1}{10}$	Aug	79	$9\frac{5}{10}$

The thermometer is noted at sunrise, 2 P. M. and dark.

We cannot but be struck with the difference in the quantity of rain that fell in August last year and this; and although the farmer has suffered ruinously in the curtailment of his corn crop, he has abundant reason for rejoicing on another score; for the same cause that shortened his crop, has preserved his family in the enjoyment of earth's greatest blessing, health. I have never known the country so healthy at this season; and I doubt very much, on balancing accounts at the end of the year, if the farmer doesn't find himself as well off with a short corn crop, as he has heretofore been with a good one: for when there is no sickness and death, there is no toll to pay the doctors, and no reduction in the capital of his estate.

I obtained a very satisfactory result from the application of sea-ore, on a part of my corn-field this year. Whilst the neighboring corn was fired above the shoot, that to which the sea-ore had been applied, suffered comparatively little or nothing. Independent of its general fertilizing properties, then, (and I have fully demonstrated them,) this additional one of attracting moisture from the atmosphere, renders it a most invaluable manure, especially upon high sandy lands.

In a former communication, I mentioned the beneficial effects I had experienced from sea-ore on wheat and oats. I was in some doubt, whether they did not depend mainly on the salt contained in it; and this year I have fully satisfied myself on the subject.

In the month of March last, I top-dressed a bed of fall wheat, one of spring wheat, and one of oats, with salt scattered by the handful, as you would sow oats. I watched the effect closely until harvest, and could at no time perceive the least benefit from the application.

I was occupied a good deal last winter in getting up new ground, and my experience may be of some use to others. I was desirous of testing the relative value of the grubbing hoe and coulter for the first breaking up of the land; and am convinced, that the labor can be performed infinitely better, and at less than one half the expense, with the coulter than with the hoe. This may be no news to many of my readers, as I know the coulter to the north and in some parts of our own state is extensively used for the purpose: but it will be to some of our low-country farmers, who have never used it, or seen it used. I first cut around the stump, and cut out the large surface roots, then run a strong coulter drawn by four or six oxen, (I used two oxen and two steady horses,) thoroughly over the ground, and afterwards cross it. A man should follow with an axe, to chop any root that may be too strong to be pulled up.

Mr. B——, an intelligent gentleman of my acquaintance, residing in this county, is this year making an experiment on the comparative expense of keeping his hogs up, and letting them run at large, until taken up in the fall to fatten. He found that his penned-hogs required something more than food, to make them thrive. He gave them sulphur and salt, which he thinks much more highly of, and asked my opinion on the subject. I advised him to give them ashes without limit: he did so; and when I saw him a few days ago, spoke in the most rapturous terms of their effects, and insists that so valuable a remedy should be generally published. I replied, it was no discovery of mine: I had heard it, and used it with great success, and presumed it was generally known. He said, it was new to him; and as it may be to many others, I communicate it for general information.

The ashes plan, however, did not take with my friend, without some opposition from an unexpected quarter. The "old lady," whose province extended to the lie-stands, entered a formal protest against this encroachment upon her domestic economy, as she should have no ashes to make soap. But when it was proved by figures, (and figures cannot lie,) that though she might be the loser in ashes, she would be the gainer in grease, like a good wife, she gave in, and is now content to abide the experiment.

This gentleman, a practical mechanic, told me of a cheap and effectual method of rendering smoke-houses and dairies rat-proof. He has repeatedly tried it himself, and induced others to try it, and always with the fullest success. After digging out your foundation, lay the first course of bricks, to extend four and a half inches all around, beyond the wall. The operation is this: the rat always burrows close to the wall, and continues to descend until he meets the obstruction of the projecting course at the bottom; finding he can go no lower, he desists. Let not the simplicity of this plan deter any from adopting it. I will, however, add one suggestion: Do not, as I once knew a gentleman to do, who, at great labor and expense, erected what he supposed would be a rat-proof corn-crib. It was placed upon eight posts, nicely hewed and smoothly covered with sheet copper. The rat could not climb here, because there was no place to stick his claws in; and it was so high from the ground, that he couldn't by any possibility jump up, and get a foot-hold: but it was also too high for the gentleman to get into, without a pair of steps; so they were put, and the enemy had no longer any necessity for blunting his claws against the copper.

Mr. B—— is an instance of what enterprise and industry will effect. He purchased his farm fifteen years ago: it was a dense forest; not an acre of cleared land attached to it; it was low, and, consequently, sickly; but he determined to make it a productive and a healthy farm, and he has succeeded. He has cut down the forest of centuries, exposed a fine, rich virgin soil, and ditched in every direction. Mr. B——, jr., who has now taken upon himself the direction of the farm, has this year cut a canal eight feet wide and four deep, upwards of a mile, and will continue it as far again. This canal will bring into cultivation as fine a body of land, when cleared, as there is in the lower country, which has heretofore been worse than useless, as it served but as a hot-bed of malaria. A portion of it is already in corn, high and dry, and suffering from the drought. The homestead embraces every building necessary for the convenience or comfort of the farm: a large mill, worked by oxen; extensive sheds, capable of covering every article of stock on the farm, from which he raises abundant supplies of best manure; stacks with shingled roofs, for the protection of his artificial grass hay; and the best corn-house I ever saw. A few such examples, and the tide of emigration from east to west would cease to flow: for land like this was can be purchased for $4 an acre.

I sowed, in February, two bushels spring-wheat, procured from Thorburn, in New York, on corn-land of fair quality. The produce was twenty-one bushels, the grain very good, better, I think, than that sown. The general opinion here is much against it. I am satisfied it never can be adopted in this climate as a substitute for winter wheat: but I think it may be sown to advantage instead of oats, on land that will produce wheat. I also procured from Thorburn, in December last, a quart of a new white wheat, recently sent out from England as a sample, with a few of the stalks, called "Ealey's gigantic." It well deserves the name, for it was the largest stalk, largest, fairest and heaviest grain, I ever saw. I drilled it in my garden and cut it on the 6th July: it yielded three bushels and a peck. The stalk was as large as the original, the heads very long and apparently well filled, but the grains were shrivelled and evidently injured whilst in blossom, by a heavy rain and wind, from which the other wheat, being more advanced, almost totally escaped.

R. Archer.

THE CULTIVATION OF MIDDLE SOUTH CAROLINA. ADDRESS OF JOSEPH E. JENKINS, ESQ., TO THE AGRICULTURAL SOCIETY OF ST. JOHNS, COLLETON, S. C. THE LOUISVILLE, CINCINNATI AND CHARLESTON RAIL ROAD.

To the Editor of the Farmers' Register.

Sir: "*In passing through the upper country,* " the planters are *astonished*, on inquiry, at learn-" ing how little use is made by us of the plough; " an instrument of *indispensable necessity* to " them !!!! but, it is easy to be accounted for; two " systems of agriculture can never be more dis-" similar, than the one used by them, and that " which obtains in this section of country. *There* " (I speak of the section through which I passed " this spring, *videlicet*, from John's Island to Co-" lumbia,) 'twould be *preposterous* to speak of ma-" nuring; from 12 to 15 acres and upwards of land " are *commonly !!!!!* planted of cotton alone; *here*, " $3\frac{1}{2}$, and, in some *rare* instances, four of cotton, " and one of corn. We have not the facilities of " shifting our fields from a worn-out spot, to a " virgin soil, *exhausting* that, and then again " *pursuing the same process*. * * * * * " Our system approaches nearer horticulture " than farming; comparatively, "*our fields are* " *perfect gardens.*" * * * * * I did not " see a field of cotton on my return from Colum-" bia, on the 5th of June, which had the appear-" ance of having had a single working, from the " time the seed had been deposited for planting, " (the planting averaged the 15th April, in 1838,) " to that day. In most of them, *the weeds and* " *grass were taller than the cotton*. * * * * * " Do not misunderstand me, gentlemen, as con-" demning their system; to them, it may be most " profitable; to us, one thing is certain, it would " be ruinous. Therefore, the hoe is the imple-" ment of husbandry with us; and a powerful in-" strument it is, in the hands of a strong and vi-" gorous people"—a people, to subsist whom and all other bipeds and quadrupeds on a plantation, one acre of corn is planted [to the hand.] !!!!! This, at least, is the average of the low country. On Mr. J.'s plantation, it is probable his servants have of fish *quantum sufficit*.

Merely observing, that the italics and marks of admiration are mine, and not the addresser's, I cannot avoid expressing my "astonishment" at a representation of middle and upper country cultivation, so grossly erroneous, and only to be excused, because it originates in innocent ignorance. For I assert, without fear of contradiction, that 12 to 15 acres are, in general, the *maximum* of good planters, for corn and cotton: that there is not a respectable planter in middle or upper Carolina, who not only does not think manuring "preposterous," but whose conduct is diametrically opposed to it, and who does not "shift his fields," not as above described, (a circumstance now wholly out of the question,) but, from one *improved* spot to another; that there are annually to be found fields of cotton on the Wateree, the Congaree, &c., which will vie with any on John's Island for horticultural neatness; that as to "the weeds, grass," &c., I know not what road this eloquent addresser travelled; but, this I know, that, in 1838, barring a short space of time, when the grass got a little ahead, most of the cotton in the middle country was very clean; and, that in the same section, there are as fastidious amateurs, fully as well acquainted with the operations of the hoe as the most astute planter in the low country.

But, what is the fiscal fact—in short, the real value of land in the middle and low country—(always excepting the sea-island cotton and the tide-rice plantations, the latter diminishing 33 per cent. in the produce for 1837-38, and Manilla and East India rice finding a profitable market in Charleston—) literally nothing—wholly abandoned. It has been sacrificed to the "precision and peculiar elegance of the hoe," to the introduction of horticulture, *vicè* agriculture, to the abandonment of the plough, to the starvation system, which arose from the substitution of cotton for rice, and the relinquishment of the inland swamps, where cattle to any extent might now be raised. Indeed, if lawyers could be driven from the public counsels, and engineering, instead of oratory, be taught at the colleges, South Carolina has the means of producing millions she does not now do. But, to return to the price of land. Tracts in the low country, sold after the revolution for guineas, are not now worth as many dollars. On the other hand, in the middle and upper country, the price is constantly increasing.—2,000 acres have recently been sold, on two years' credit, for $20,-000, which, in the low country, would not produce a tithe of the sum—8,000 acres, sold by an emigrant for $2 50, are now worth $5, if not $10 per acre. The simple reason, the superior cultivation, greater produce of provisions, infinitely better treatment of negroes, and the employment of respectable overseers; for, planting, as they do, five acres of corn to the hand, —— acres of oats, wheat, potatoes and peas, (with the corn,) so to act is no matter of difficulty, any more than there is to be discovered an impediment to an allowance of half a pound of good bacon *per diem* to a laborer, or the payment of an adequate salary to a humane manager. [*Vide* an article at p. 269, Farmers' Register.]

In consequence of this system, the planter makes his three, four, or five bales to the hand; and, remembering the facilities of shifting fields, &c., I would observe, that I have known a bale to the acre, produced by a planter, who manures with cotton-seed, clay, leaves, &c., from land that has been cleared thirty years; and, it is not more than four years since, that on discussing the subject with four planters, in the same neighborhood, it was determined that, for every bale produced a few years before, four were now sent to market—the plough, the agent. Fields thus productive, do not permit the growth of grass, &c., though after the fodder is gathered, good crops of crow-foot grass are reaped from the corn-field.

The editor of the 'Southern Agriculturist,' (p. 414, Aug. number,) alluding to an idea of your's, laments the want of county agricultural surveys. Their want is evident in Mr. Jenkins's errors; and, while such universal ignorance, so great a disposition to cherish that ignorance, and entertain such monstrous misconceptions of the more correct management and the greater wealth and equal civilisation of the upper and middle districts, prevail in the low-country, the prospects of the south, and South Carolina especially, are dark, dark indeed. In the expenditure of the public money, it has given rise to an absolute proscription of all east South Carolina, and a denial of instrumental surveys to sections loudly and fairly calling for them. The rail-road has been made to run in such a direction as to exclude any access to the provisions of the west from east South Carolina. It has been carried, at an enormous and increased expense, to Branchville, *via* Orangeburg, in fact, to a rail-road, that cannot carry cotton down at any reasonable charge, and receives and spends $1,000 per diem, or only $320,000 per annum. This is the rail-road that is to compete with the almost completed scheme of Georgia and Tennessee—a scheme, in which, *nolens volens*, the "ancient dominion" must join. There will soon be free access, from the Atlantic at Savannah to Knoxville, which may be said to be equi-distant from the James at Richmond and Petersburg, and Charleston and Savannah. On its north-east *terminus* and in the more populous and productive character of its whole line, (lessening it to one-third if not one-quarter the distance,*) the full and forcible effect of western commerce will be felt; for, nothing can prevent a road from Knoxville to Abingdon, and thence to Lynchburg. Again, North Carolina will aid by a road along the Piedmont route to Danville, thus opening another highway to Petersburg and Richmond. To these outlets for western commerce, we may add the Baltimore and Ohio rail-road, the Mercer, (Chesapeake and Ohio) canal—ensuring to the Chesapeake bay, &c., the GREAT DEPOT; also, the Pennsylvania and Erie canals—canals coming, as well as the Mercer, into competition with an overwhelming power, if, as is said to be the case in Great Britain, boats can be towed at the rate of six or nine miles an hour by steam.

But, what is "the dominion" about? In the Knoxville Register, in a paragraph, most probably written in Charleston, we find "the main ob-" ject of the Augusta convention is to establish a " *direct* trade *from the south* directly to Europe. * " * * * East Tennessee is particularly and " vitally interested. It is important to her, *be-" cause* it throws *our* exports and imports into the " same channel." Now, gentlemen of Knoxville, permit me to ask you, for what "exports and imports" you can find a market in Charleston, (the very existence of which, as a harbor, according to the engineer Holmes*, is threatened,) equal to that on the borders of the James? None, whatever; and you would have done better by an access to Sumpter, &c., districts in South Carolina, than you possibly can in Charleston, the market of which, in bacon and corn, is to be glutted by a single train of cars; and, indeed, you had better now pray the board to take this route into its serious consideration. But, I forget myself; that is not the object of your paragraph, or of the meeting—the intention being to puff the bank and prepare the speculators to plunder the public, and fill their own pockets. It is to this effect, that they tell you their mighty agent is to sell the South Carolina bonds, bearing five per cent. interest, at par, in Amsterdam, when five per cent. New York stock is worth but ninety in London; or rather, that he can get *a premium* for them, and get money for three per cent. They have also *said* Mr. Biddle has pronounced the charter worth millions. But, there are other *becauses*—"*be-" cause*, after the establishment of the south-" western bank, (five-sixths of which are held in " Charleston and Columbia,) the rate of exchange " will be reduced *to almost nothing;* and, *because* " by a direct shipment of the great southern sta-" ples, and a direct re-shipment of European fab-" rics, the factorage and commissions now paid at " the north, *will be entirely taken off* !!!!! and " our foreign fabrics made, *by so much*, intrinsi-" cally cheaper."

It is for the sage of Knoxville to demonstrate, how exchange is to be reduced by an issue of paper, and this only payable in Charleston, the capital of a state, not having more than 300,000 whites. I have been even stupid enough to believe it was regulated by the material passing to and fro, sold and consumed. What the latter is of 35,000 persons, two-thirds negroes, in Charleston, had better be first ascertained, as well as whether, should cotton fall in price, South Carolina will not necessarily be compelled to supply herself. But the *direct* shipment is the reliance; as if it did not and had not existed for years. Only the home consumption may be said to be consigned (in 1837-8, 54,280 out of 279,957 to the 25th August, from Charleston,) to the north.† This year, Georgia and South Carolina have shipped nearly 600,000 bales, little of it going to the north. How the factorage and commissions are to be saved, is beyond my humble comprehension. Is Charleston to do the business for nothing?

I will conclude this paper by a reference to the

* See a paper as to the New York canal, and what it brings *from* the west, in a late Farmers' Register.

* "Should the uninterrupted passages of water, by the course thus formed, continue, it is greatly to be feared that a few years, if not months, will effect a total change of the currents passing by our wharves; that Hog Island will become the north channel, and the channel in front of our wharves be obstructed by large sand deposits; that the entire western portion of Sullivan's Island, including Fort Moultrie, will be swept away, thus widening the entrance to our harbor, which must substitute *sand flats* for *the channels on the bar*, and leave the city and harbor "exposed to the unchecked violence of destructive storms." Three forts at the site of Fort Johnson, and three at Fort Moultrie, have already been destroyed.

‡ A tabular statement of direct and indirect shipments for a few years back, would be instructive.

8th section of the bank act, "declaring directors and capital distinct and separate;" and, that the bank "shall never be liable for the debts of the " rail-road company; but the rail-road company " *shall be liable for the bank* in case of failure;" and, then add, in nearly General Hayne's own words, how, after all the dramatic management in Nashville and Columbia, the affair of the bank was concocted. Eight millions were to be subscribed by the 31st December, 1837, to secure the charter. After Tennessee had assented and paid to the amount of $650,000 for roads in her own state, the subscription amounted to but $5,300,-000. The only means of effecting this important object, was the purchase of the Charleston and Hamburg road, the stockholders of which becoming subscribers in the Louisville, Cincinnati and Charleston road, added a subscription of 20,000 shares, leaving a deficiency of only 7,000 shares, or $700,000, to make up the $8,000,000. But $8,000,000 were necessary for the first instalment due to the Charleston company. Of this sum, there was borrowed $700,000 of the banks, and $100,000 city stock was *liberally* advanced by the corporation of Charleston.

The company have restricted themselves to 35 cents per 100 lbs. for 100 miles, as charge for freight. In Georgia it is 50 cents. Thus, a barrel of flour by the Carolina road, will, for 400 miles, pay but $2.80—by the Georgian $4.00. Now, the Pensylvanians bring flour from Pittsburg to Philadelphia for $1.12½. What will be the freight when the Mercer and Pennsylvania canals, the Baltimore and Ohio rail-road and the James river improvements are completed? What too, will be the difference of the shipping expense on the Patapsco and the James, and at Charleston and Savannah? These, which I take to be facts, give us the reason why Georgia can go to New York and get money at five per cent. and South Carolina be compelled to go to England, and possibly for—nothing.

President Hayne, in his call, (1838,) talks of lower rates. "The charge, (he adds,) for cotton " from Hamburg to Charleston, has never, we " believe, exceeded 25 cents (per 100 lbs. or for a " bale, $1,) and has been as low as 18 cents, (or " 75 cents per bale,) or one-half the rates allow-" ed by law." (pp. 14, 15.) Now, what says President Tupper? He states the power on the road to be equal to the business, "except cotton " down, *when the steamers were stopped for the " want of water*. Their charge was 75 cents; " that of the rail-road in 1837, $1.50 cents—of " course, the latter never carrying any important " amount. For the last three months, we have " been obliged to send up empty cars to bring " down cotton, there not being up-freight enough. " This has increased the expense without ade-" quate profit, *the expenses being about equal " to the amount received, when the cars are only " loaded with cotton down*." (Report 1st January, 1838.) The cost of the Charleston road was $125 per share in old stock, (now worth $112,) 25 per cent. on new stock payable for every share sold, in one share in the Louisville, Cincinnati and Charleston company's stock, with £5 paid thereon.* The balance one-third in cash, one-third in one year, and one-third in two years with interest and mortgage. The property apparently not yet rendered. G. L. C.

* By the 8th section forfeiture is allowed. General Hayne, in his 1836 address, said, "*he will always be at liberty to forfeit his shares;*" so that the Charleston and Hamburg rail-road company may do the same. In three years they will get $2,400,000, and $5 per share, reducing it $100,000—but what is obtaining $125 for what is worth but $112, and clear of a crazy concern?

From the Farmers' Cabinet.

CULTURE OF ONIONS.

The town of Wethersfield (Conn.) has long been famous for the large quantities of onions which are annually raised and exported to the West Indies and the southern states. It has been superstitiously supposed there is something in the soil of Wethersfield peculiarly adapted to the culture of onions; and this whim has no doubt discouraged many from attempting the cultivation of this valuable root, in other sections of the country, equally favorable to its growth. It is true the soil of Wethersfield is a rich gravelly and sandy loam, well adapted to horticultural purposes; but the success of its inhabitants in the culture of onions, is attributable in a much greater degree, to a particular virtue in the fingers of its females, than any peculiar properties in its soil.

The business of raising onions in Wethersfield, is reduced to a perfect system. The following is the method of cultivation. Early in the spring the land is manured by ploughing in fine manure from the stable or barn-yard, in the proportion of about ten loads to the acre. That of neat cattle is preferred, as that of horses is considered of too heating a nature. After the manure is ploughed in, the land is well harrowed and laid out into beds five feet wide. The beds are laid out by turning a furrow towards them each way. This raises the beds above the aisles and gives an opportunity for the water to run off should there be occasion for it. They are then raked with an iron-tooth, or common hay-rake, and the aisles suffered to remain as left by the plough. Thus prepared, the beds are ready to receive the seeds.

As early as the season will admit, the seed is sown in the following manner. A rake, with teeth a foot apart, is drawn crosswise of the beds, for the purpose of making drills for the reception of the seed. The seed is then sowed in the drill, with the thumb and fingers, and covered with the hand. From ten to twelve pounds of seed is put upon an acre. After the plants come up they are kept free of weeds, which generally require four weedings. A hoe of a suitable width to pass between the rows is used in weeding, which saves much labor. When ripe they are pulled and the tops cut off with a knife. A sufficient length of top is left to tie them to the straw in roping. They are then roped, or bunched in ropes or bunches of 3½ pounds, as required by the law of the state. An ordinary crop is from 6000 to 8000 ropes to the acre. The quantity annually raised in the town, is estimated from 1,000,000 to 1,500,000 ropes which are sold at an average price of $2 a hundred, amounting to from $20,000 to $30,000.

Most of the labor in raising onions in Wethersfield, is performed by females. The cultivation of an acre requires from fifty to sixty days' labor of a female, whose wages, including board, is about forty-two cents a day. Though many of the young ladies of Wethersfield spend a portion of their time in onion gardens; yet in personal beauty, education and politeness, they are not excelled by females of far less industrious habits.—*Connecticut paper.*

From the Pittsburger.

FOUL AND POISONOUS EARTHEN WARE.

Mr. Editor.—Sir: Will you permit me to acquaint the public, through your valuable journal, that there is a kind of crockery ware, manufactured in almost every city in the union, which is dangerous to use—and which the public will understand by the term common red pottery. This ware is made of common clays from the brick yards, and when formed, is coated with a liquid called glaze, which is nothing less than a coat of lead. The clays being of the commonest kind, cannot be subjected to any heat in the burning that will make them safe for family use—*being porous*—and it is very unsafe to deposit any articles of family use in them, such as milk, butter, or in fact water, as a portion of the lead glazing will be extracted, and the article will, in consequence, become dangerous to use. I have noticed no fewer then ten instances within the last twelve months, of familes sustaining injury by the use of such ware.

In selecting the article of crockery that is suitble for family use, it is only necessary to ascertain that the body of the ware—the clay—has been hard burnt, which any person can understand by the sound of it—if well burnt, it will have a clear sound. The poorest kind will not ring at all, and therefore can be easily detected. An article of this kind will, in the course of a month's use, become very foul. Let any one who doubts this break the vessel, and they will ascertain the fact. There is a kind of ware, however, that is manfactured in almost every city in the union, called stone ware, which is perfectly good for family use. This ware is formed of strong and superior clays, and undergoes a great heat in the burning,—and moreover, the glazing is not a thick coat of lead, but is accomplished by throwing salt into the kiln. All kinds of Liverpool ware are adapted to all purposes of family use, being made of sound clays and well burnt. As a preventive is better than a cure, if I should be the means of preventing any person suffering from the use of the poisonous article—lead—this advertisement will answer the ends I design.

C. S.

From the Farmers' Cabinet.

DIFFERENCE OF PLANTING CORN ON GRASS AND STUBBLE LAND.

It has been the prevailing custom with the farmers of New Jersey, for many years, to plough their sward for corn, that they might raise more than in tilling otherwise. I admit it is a good mode to till on the sward, and has always been allowed so by first rate farmers; but I find it greatly to my advantage to reverse the practice, in order to prevent the worm making such sad havoc in my corn-fields. About six years ago I planted twenty acres on the sward, and out of that the worms took eight, scarcely leaving a hill to be seen. The tenth day of June I had it planted over again, thinking the worms would not disturb it so late in the season, but still they preyed upon it, leaving about one half to grow. The next spring, I came to the conclusion to farm differently; instead of ploughing the sward, I ploughed up my stubble field, gave it a good harrowing, furrowed it out both ways, marled and manured every hill, and then planted the corn. In about a fortnight, I made a visit to the field for the express purpose to see if my corn had got up, or if the worms were taking it as they formerly had. I must acknowledge, that never since I have been a farmer, have I had my corn to come up as well; and I am fully satisfied, that is the best manner to farm where we are harassed with worms and other insects. Although the field which I farmed had two crops in succession; yet, notwithstanding, the third crop was much better, sounder corn, than I had raised for many years till I adopted this plan.

The manure I had left was considerable, after taking out enough to go over the corn-field; and of the remaining part I made a compost, mixed with marl or lime, which make it much better for wheat than to put it on in separate bodies or portions.

The field that came in regular rotation to plant with corn, I ploughed up for wheat and rye. After the process of ploughing was over, I took a three horse harrow, gave it a thorough harrowing both ways, to make the furrows lay level, that the grass roots might rot. Before the usual time of sowing came on, I took what manure I had, put it on regularly, till it was gone. The part of the field which had no manure, I sowed in rye, and the part which was manured I sowed in wheat. Thus I have farmed for five years, with much better success than I ever did in the same length of time previously.

From the Baltimore Farmer and Gardener.

CARROT FIELD CULTURE.

We had a conversation a few days since with a Yankee farmer, on the above subject, and being pleased with the course of his remarks, we prevailed on him to commit them to writing, in the hope that as the season is now approaching when this fine vegetable may be sown, we might, by bringing the topic to the notice of our readers, induce some of them to try the experiment of raising a crop for feed for their milch cows. The parsnip too, should command attention; the same mode of culture will serve for them as for the carrot, with these exceptions—that the drills should be about 18 inches apart and the plants stand about 4 inches asunder. Thus planted in the month of April, in suitable soil manured with well rotted manure, or a compost of spent ashes and mould, kept clean and hoed three times, they would yield from 500 to 1,000 bushels of roots to the acre, which might be left in the ground all winter to be dug as wanted for feeding.

To those who desire to have butter in winter, possessing all the virtues of that article made from cows fed on May pastures, it will be only necessary to say that by a very little trouble they may realize their wishes.

The communication alluded to above will be found subjoined.

"The carrot flourishes best on a loam or sandy soil. The ground should be prepared by ploughing very fine to the depth of ten or twelve inches, fine manure, in quantity sufficient for common crops should be ploughed in, and the ground harrowed merely sufficient to level it, the seed should be sown in drills from twelve to fourteen inches apart; a machine made for the purpose is the best for sowing: four or five plants to a foot is sufficient to be left to come to maturity; a good day for planting corn is a good day for sowing carrot seed. The crop is usually from four to five hundred bushels to the acre. There is not a more profitable crop for feeding stock, raised in the N. England States, than the carrot, where the soil suits the crop; with a little more labor, you will get as many bushels of a much richer vegetable than the potato. One experiment has been made, by putting six cows into the stalls in December, and feeding five with corn-meal and hay, and one with corn-meal and carrots, and when slaughtered, the one fed with carrots was pronounced the fattest and handsomest beef. They are equally good for milch cows, increasing the quantity, and adding color and richness of flavor to the butter, but little, if any, surpassed by the best pasturing. They can be profitably used in many others ways by a farmer."

THE DROUGHT. THE GREEN SPRING LANDS OF LOUISA COUNTY.

To the Editor of the Farmers' Register.

Fluvanna, Sept. 10, 1838.

In compliance with a request in your last number of the Register, that reports of seasons and crops might be made to that journal from the different sections of country in which it circulates, I give you one which I am sure cannot be surpassed in melancholy of detail by any that may appear from other quarters. Confining myself to the section of country between the James and Rappahannock rivers, parallel with, and extending thirty miles below, the South-West Mountains, I can say from ocular proof and certain information, that no drought has ever come under the observation of the oldest inhabitant, that will compare in severity with that which has visited this country since about the middle of June. Within this range, I have heard of but one neighborhood, (about New Canton, on James river,) in which the corn and tobacco crops have been at all benefited by rain. On other water-courses, and on good highlands, they have been curtailed from more than half to *nothing* on inferior grades of soil. Pastures and meadows are burnt up, and the most luxuriant green-sward turf in our yards destroyed even to the root. To add to these grievances, the little fodder that had escaped being entirely blasted by drought, and a sirocco-like wind, which has prevailed throughout the summer, was killed on most flat lands by a *frost*, which occurred on the night of the 3d instant biting also, and in some instances destroying, a portion of the tobacco on low situations, particularly in those wanting sufficient circumambient moisture to protect them. For a week past, there has not been a mill within fifty miles of my residence that can grind more than a few hours in the mornings, and very few of them *at all.* Indeed, such is the impracticability of procuring meal, that I keep a man constantly beating coarse meal and hominy for my negroes, having neither potatoes nor peas from large plantings, to substitute for bread. *I* shall not want another such season to admonish me of the importance of a horse-mill on every farm where water-power cannot be relied on. Wheat crops have been fine throughout this country, but for want of corn the *small* farmers and planters and many of the *larger* ones will be compelled to use from the whole to a part of what is made, for bread and horse feed. By the way, could not your *disinterested* Baltimore correspondent R., *extend* his benevolence to our starving community—after first taking care of Maryland—in telling us whereabout in Virginia he ever saw such abundant crops of corn at $1 and $1 50 per barrel? Or might he not be induced to *change* his trade for the sake of a profit of two or three hundred per cent., which *I* (who am also "well known") will ensure him?* On a late visit to the Green Springs neighborhood, in the county of Louisa, I found that this *truly* green and fertile country had been visited by the same desolating evil, to a degree which an acquaintance with it of nearly thirty years had not allowed me to conceive. Still, it was refreshing to one whose sight as well as *hopes* from the soil had been seared by the presence of a universal desert, which had taken the place of luxuriant fields and green meadows at home, to witness even the partial contrast presented to the eye by the more flourishing appearance of vegetation here, where, superadded to the superiority of soil, there had been *one* shower more than was general in the parched region, which is the subject of my remarks. Had other evidence of the favored condition of this delightful country been wanting, the comparatively fat herds of *improved* cattle and flocks of Bakewell sheep with their creased backs and well-covered ribs, were enough to satisfy me of the superior richness of its grasses. By-the-by, *sheep* delight in and will fatten most kindly on grass partially killed by drought.

It may not be unacceptable to you, Mr. Editor, who feel, I know, a fostering interest in all that concerns the agriculture of Virginia, to receive some accounts of this garden-spot of it, which I believe you have never visited. The cognomen, "Green Springs," is, I suppose, derived from the mineral springs in the heart of this tract of country, on the property of Dr. James M. Morris. They were once very much resorted to, and with great benefit to invalids. Their constituent properties are said to be, (as the flavor of the water

---

*The piece referred to was not a communication to this journal, but to a Baltimore paper. It was copied (for exposure) in the report on the "Season and state of crops," which accompanied No. 6, in an extra sheet, and which will be republished, immediately following this communication.—Ed. Far. Reg.

indicates) sulphate of magnesia, iron and sulphur; the springs are as bold and salubrious as they ever were. The wealthy proprietor has thought fit to suffer the improvements to go to decay, or they would doubtless be again the fountain of resort to many of the thirsty pilgrims who now seek health and pleasure in our mountains, where I think the waters little or no more salubrious, and the *mutton, certainly*, not as fine as at the Green Springs. This valuable body of land is, so to speak, a basin of about 10,000 acres, which seems, by a sport of nature, to have been dropped into the midst of one of the most barren districts of Virginia. Its upper margin reaches to within about ten miles of Peter's mountain—the tallest in the south-west range—is watered by five creeks and the river South Anna; the latter bounding its north-eastern extremity. One of the creeks, (the south-eastern,) and a barren ridge, in which most of the creeks rise, reaches across the north-western boundary. The fine character of this soil, is doubtless owing, in great part, to these water-courses, which all (but one, and on that lies very little of what is called Green Spring land,) disembogue into the South Anna at one point, in the farm of the late Major Watson, sen'r. In further proof of the intensity of the drought, I will here remark, that the beds of all of these usually bold streams, including the river, are now as dry as their banks, except here and there a stagnant pool, scarcely sufficient to slake the thirst of the cattle, which depend on them for existence. The principal farms in this tract belong to the descendants of Major Watson, dec'd., to Dr. J. M. Morris, and to the descendants of Mr. William Morris, dec'd. Of these, the Watson estate is considered the best; containing in all about 3,000 acres. Dr. Morris's may be rated next; and I cannot overlook, in this classification, a small, sub-divided tract, belonging to a family of Branches, equal, by *nature*, to the best. Mr. Wm. Ragland's, and a small portion of a farm lately sold by Richmond Terril, Esq., include nearly the whole of this body of land. The most interesting, and by far the most important feature in these lands, is, their remarkable adaptation to plaster, which has produced in the last ten or fifteen years a change in the face of this country, that is really miraculous. Dr. George Watson, of Richmond, owns, I think, the most beautiful and fertile farm, (with a few exceptions on James river,) that I know of in Virginia. He has been the most liberal user of plaster and clover, as well as improver in the exclusion of stock, in the neighborhood, though all are now reaping, in the fullest sense of the term, a rich harvest from these measures. There is no part of Virginia on which plaster acts more powerfully than here. The soil is generally of a dark-gray color, intermixed with small, round, ferruginous gravel, lying on three varieties of clay, red, yellow and blue—all tenacious. It has been analyzed, I understand, by Professor Rogers, and found to contain a large proportion of lime. On the surface of the country, is to be seen a quantity of grayish-black hornblende, the disintegration of which gives a very rich yield of lime. In conclusion, I cannot say more for this delightful body of land, and its peculiar susceptibility to improvement from clover and plaster, than that the Watson estate and Dr. Morris's have produced this year 19,000 bushels of wheat, at 23 bushels to the acre, when, 15 years ago, one-fourth of that quantity would have been considered a very fine crop. The crops of corn and tobacco on these estates are sufficient for their consumption—tobacco better than I have seen off of James river—and one of their great staples, (the finest bacon and mutton in the *world*,) as promising as it can be. H.

SEASON AND STATE OF CROPS, IN AUGUST.

[Republished from the supplement to the last No.]

During the latter part of August we were absent from home and from editorial labors, for ten days, on a visit to the Fauquier Springs. It was the first time, since undertaking these labors and duties, that we have taken even half so much time of absence, for pleasure, health, or relaxation and rest; and we find that this, in spite of all precautions taken, has been productive of inconvenient omissions. The most important of these will be partially supplied by the issuing this extra sheet to accompany No. 6 of the Farmers' Register, of which the last pages had been printed before our return.

Reports of the season and state of crops, from the subscribers and correspondents of the Farmers' Register, have become so rare and irregular, and their receipt so little to be counted on, that we had ceased, (though with much regret,) to look for them, as matter for each monthly publication. Such reports are always the most numerous under the most disastrous circumstances; and the recent unprecedented state of heat and drought, and the general suffering of all growing crops, have served to bring more information than would come in half a year of prosperity and good prospects. At some cost and trouble, the failure to attend to these favors will be supplied by this extra publication, which will be sent with every copy of the September number, now ready to be issued, and the same will be also copied into the next succeeding number.

We shall copy below a few of the most distinct and full statements which formed parts of letters that awaited our return. But far more full and general information was gained by personal observation on our journey, and from the numerous intelligent farmers whom we met at the Fauquier Springs, from various parts of lower and middle Virginia, and from adjacent states. It is needless to particularize. The hot and dry weather has been more or less mitigated in numerous places by partial rains, some of which fell heavily and abundantly, for the time, when the country around generally remained parched, and but a small extent was even sprinkled. But scarcely any where did these partial and limited supplies of rain come soon enough to prevent a great diminution in the growing corn-crops; nor did the effects continue as long as was necessary to prevent renewed damage from drought afterwards. Reports of great and certain injury from the drought are heard from almost every part of lower and middle Virginia, (with the exception, perhaps, of very small sections that have been peculiarly favored,) and from the northern valley counties, west of the Blue Ridge mountains, from the Eastern Shore of Maryland, New Jersey, and Pennsylvania. The newspapers are now full of such reports, which would extend the damage much farther; but we limit our views to what has been either seen or heard of in conversation with well informed and highly respectable observers of the scenes described, or obtained from correspondents, as much to be relied on.

In Gloucester only have we heard of even average crops of corn being expected; and two gentlemen from that county are the only persons heard from, who expect themselves to make better than average crops. The letter of one (August 4,) is given below; the other was seen as late as August 24. Also, on a few of the best farms on the lower part of James river, fair crops of corn are expected. Some of the poorer lands by the railway between Richmond and Fredericksburg do not seem to have suffered so much by drought, as by other causes of unproductiveness. Elsewhere, no estimate of any county would put the diminution of the corn crops at less than one-fourth below an average, and more frequently the estimate of loss would be one-half or more. We hope and trust that very few parts of the state have suffered half as much as the generally poor country of Stafford and lower Fauquier, which stretches from Fredericksburg to the Springs. The damage here must amount to 75 per cent. unless the land is totally worthless for corn in the best of seasons. The greater number of acres seen on the whole route of 36 miles will not yield three bushels of corn each—and many acres will not make even one bushel to each. The drought extends, with its worst effects, over the rich grazing lands of upper Fauquier, Albemarle, and the other Piedmont range of lands generally.

We know by experience the difficulty of forming in advance estimates of the product of growing crops; and also it is certain that the greater the calamity, the more it is magnified and exaggerated by the imagination and the fears of even the most cautious and judicious, as well as the most respectable and veracious farmers. Therefore we strike off a large amount of the usual estimates of general loss when we suppose that the present corn crop will be from one-fourth to one-third below an average gross product; and that through all the great regions spoken of above, there will be certainly no surplus, even if not a great deficiency to be supplied by importations from distant and more fortunate places. Gloucester, the only county in Virginia from which any *good* crops are reported, is part of a fine corn-producing district. From the next adjoining counties, and from the Eastern Shore of Virginia, nothing has been heard. The northern neck, or peninsula between the Potomac and Rappahannock, has shared in the general drought.

Even in places where heavy rains have fallen, and more than once, the injury is very great. The prevalence and unremitting action of great heat have been such, that the heaviest rains seemed to be entirely evaporated in a few days. During parts of July and August, and for several weeks, with very short intervals of cooler weather, the thermometer was from 90 to 95 degrees, at the maximum height, in the shade, in the country places in lower and middle Virginia, and from 95 to 100 degrees, and sometimes more, in the towns.

By information from North Carolina, the crops have suffered as severely by drought, in the upper parts of Northampton and Halifax, and in Warren, Granville, Caswell and Wake counties. On the low-grounds of the lower Roanoke (a very rich and highly important corn district,) the season has been favorable enough to promise average crops.

In Kentucky, as late as August 17, the season had been highly favorable to corn and other crops.

The crop of wheat, as stated in the notice in No. 5, has fallen much short of early expectations, and over a much wider extent of country than was then known. The unusually large proportion of straw, caused the general error of estimate. For the corn and other growing crops, we beg leave now to add the following particular statements of correspondents, to the general digest above.

"Gloucester, Va. August 6th, 1838.

"I have just shipped my crop of wheat, which averaged nine bushels to one sowed, all of it on corn-land. The promise from the amount of straw on the land was much greater. The quality of the grain is fair. The season has been favorable for the corn crops in Gloucester; and I think a full crop must be made, even if there should be no more rain, the ground being now thoroughly soaked. But in this favored region the rains come with such regularity and frequency, that the poor and backward lands will no doubt be visited to the hearts' content of the farmers."

—

"Buckingham, August 10th, 1838.

"The drought throughout this region is fearful. A bushel of corn to the acre will not be gathered from thousands of acres of the hill-land crop. May you not render a valuable service to the community, by a condensed exhibition, in your next or an early number of the 'Register,' of the most economical means of feeding stock, &c. How hogs are to be fattened this fall, and how a stock for the future is to be maintained through the winter, are important inquiries, in the solution of which you may afford important aid."

—

"Lunenburg Co. August 10th, 1838.

"Our agricultural operations are quite at a stand for the present; we are now experiencing the most distressing drought I have known for many years, if in my life. For several miles around my neighborhood, and in the vicinity of Mecklenburg Court-house, it really looks as if many, whose prospects were good a few weeks ago for an average crop of corn, will not now make scarcely a third or a fourth of a crop—some say scarcely seed—if it does not rain soon. The tobacco-crop cut short, I think, half, if not more."

—

"Halifax, Va. August 12th, 1838.

"As I am at leisure this evening, I will drop you a few lines, partly on business, and for the purpose of giving your readers, through the medium of your 'Register,' a faint account of our crops that *are* made, and those that are not made, and, I fear, never will be, to any sort of perfection. Our wheat-crop was thought by some, previous to its being cut, to be very fine in quality, and promising good quantity; but, I believe, all, or at least the greater part, now admit themselves to have been deceived. The grain is generally small, and rather shrivelled than otherwise. The quantity is generally below the common estimate. As far as I have seen or heard, our oat-crop was next to a failure. At this time the corn-crop is suffering more from drought than I recollect to have ever seen one. It is nearly spent: in fact, I fear that it is entirely so. If rain does not come in a few days, I think we may not expect but little over half a crop in this upper part of the county; indeed, I do not know or hear of any part of this county, Pittsylvania, or Campbell, where the drought does not prevail to an alarming extent. Our tobacco-crops, of course, are very backward, and are beginning to burn more at bottom than they grow at top. Tobacco, however, is a part of our crops that will recover from the effects of drought, when all hopes are *apparently* gone. If it should shortly rain plentifully, and be a late fall, we may yet make respectable crops of tobacco; but, at present, the prospects for corn and tobacco are dreadful—defying all accurate description."

—

"MIDDLESEX, N. J. August 13th, 1838.

"Our farming prospects in this section of the country are *very* dull. Up to the middle of June, the prospect never was so flattering. Corn, potatoes, barley, oats, all as promising as could be desired. Since that time, however, we have had no rain that has done any thing but scald—the mercury ranging from 80° to 98° in the shade. The corn half way up the stalk is dead, one-third destitute of ears, and the residue so miserable, that no calculation can be formed of the result. Potatoes, of which many thousands of acres have been planted, will be an entire loss. Barley and oats half a crop. Rye very poor and shrunk. Buckwheat, on which great dependence is placed for winter bread, in many cases never came up, and on the whole only one-fourth of an average crop can be realized. Last night we had a thunder-shower, and slight rain from the south; but all is bright and hot again. Thermometer 91° at 10 A. M."

—

"PRINCESS ANNE, VA. August 14th, 1838.

"We have had the driest and hottest weather I have ever seen or felt here. We have not had a good rain since the 18th of June, and only one or two light showers since that time. A great deal of our corn is burned up to the ear, and we cannot make more than half or two-thirds of a crop."

—

"QUEEN ANN'S CO., MD., August 17, 1838.

"While writing, I will take leave to add, that never, I believe, within the memory of our oldest people, has this section of our country been visited with so early and destructive a drought as that which we have lately experienced. Our crops of corn, potatoes, &c. are nearly destroyed; and it is generally thought, so far as I have heard, and so far as my own observation extends, it verifies the opinion, that this peninsula cannot now, whatever rains may come, even the most favorable, make any thing like corn sufficient for its necessary consumption. Our clover fields are burnt up, with scarcely the appearance of vegetation upon them, even since the late rains. Indeed, the whole face of the country wears a most melancholy aspect. We made large crops of straw, in proportion to the ground sown in wheat; which was less, probably, from a fourth to a third of that which, some years ago, used to be put in that grain. The yield from the straw, however, is much less—say from twenty to thirty per cent.—than a fair average, owing principally to rust. The rye and oats crops also turn out badly. But enough of this lugubrious matter."

—

"FROM LOUISVILLE, KY., August 17.

"We have had through the months of June and July, and so far in August, the most favorable weather; plenty of rain and the crops of wheat, corn, &c., are superabundant. Owing to the scarcity of plants, the coldness of the spring, and the low prices last season, there will be a small crop of tobacco made."

—

COGGIN'S POINT, PR. GEORGE, VA., Aug. 26.

"Our corn crop, I much fear, threatens to be even worse than I had anticipated. The stalks had made so much improvement in growth, that I thought some weeks back, there might be some approach to an average crop made on this farm. A careful examination yesterday confirms my later and worst fears. Though the stalks look generally well, the number that are without ears I would suppose to be nearly one-third; and the remaining two-thirds are very indifferent. This is what I feared would be the result, from the burning up by the extreme drought (as formerly stated,) of so great a proportion of the tassels, before the exhibition of the silks; but the extent of injury from this cause is much greater than I had anticipated. All prospects of even half a crop here, I fear, are now dissipated.

Directly in contradiction to all such accounts, from these and numerous other less authentic sources which all the newspapers are full of, the following communication appeared in the 'Baltimore Patriot' of August 17th. We know not whether it was to this very positive, and seemingly very plausible statement, or to other causes, that was owing the latter part of the remarkable occurrence in the Baltimore market of a sudden rise in the price of corn, of 15 cents or more, in the bushel, and as sudden a fall to the first mark, and all within a few days.

[To the Editor of the Baltimore Patriot.]

"I having seen a dreadful account given in the public prints, concerning the failure of crops, which by all appearance, has caused a great rise in the price of grain. I, as a well known citizen of Baltimore, deem it my duty to let the commercial part of the citizens know the true state of the crops of grain in Virginia and North Carolina. I was continually travelling in the above states, from the first of June to the first of August, and have been accustomed to travel in the same states for the last eighteen years, and do say, I never saw such fine crops of corn and wheat before, in any place; and I heard it asserted, they excelled the crops of any season ever recollected, by the oldest farmers—the corn was getting hard then, and considered as good as made. Some of the farmers had succeeded in engaging their growing crops of corn at one dollar and fifty cents per barrel, but that price could not be easily obtained. I heard a farmer say that he did expect corn to be as low as one dollar per barrel, at the heap when gathered.

I write the above for the benefit of my fellow citizens, that they may know how to make their purchases. And if any gentleman should suspect me of having any personal interest in view in the matter, I assure them, I am neither a merchant nor speculator in any article whatsoever; and they can have my name by applying at the Patriot office. R."

If some of our subscribers, in every different region, would regularly furnish monthly reports of the state of crops, so as to enable us to present in extracts from their letters a full and authentic statement of the general condition of the country, it would be of great value, as information, to the readers of this publication, and to the country at large. One of the certain effects would be to prevent groundless panics in the markets, and also to extinguish such reporters as the author of the foregoing communication.

August 29, 1838. ED FAR. REG.

—

EXTRACTS OF PRIVATE CORRESPONDENCE. SEASON AND STATE OF CROPS.

Hanover, September 5, 1838.

"We have made more than half an average crop of corn in this neighborhood, notwithstanding the long continuance of the drought. I have, however, seen many fields of corn between this and Charlottesville, which will fall below half an average crop. While in the neighborhood of William Fulcher, of this county, I understood that he had last year commenced seeding wheat the latter part of August, finishing in September; and that his crop was considered a good one. I did not see Mr. F. himself, but some of his near neighbors gave me this information. While I was in the habit of making wheat, I generally found the 10th of October to be the best time to begin: of course was much surprised to hear that seeding had been successful so much earlier."

—

Brunswick, Sept. 8, 1838.

"The high price of the mulberry is retarding the culture of silk, much to its injury. I had determined to retain 20,000 of my best trees; but I could not stand the temptation of the price offered for them, in these dry and high-pressure times. I am extremely anxious that the culture of silk should succeed in this section. Our soil is gone—no lime, no marl—and the litter very poor with which we used to manure our lands, such as oak-leaves, &c. It is really discouraging to view the galls and gullies on our farms, and more fatiguing to walk over them; for the gullies are so wide you can't jump them; they must be headed. We must either turn our attention to some other crop. that is not such an exhauster of land, or desert the country. I am now done with the cotton and tobacco crops on my home plantation, and shall rely on the silk crop to sustain me; and, instead of improving a few acres of land for cotton or tobacco, I shall have time to manure double the quantity of land, which will increase my grain crop, so much needed at this time."

—

September 10, 1838.

"I have no knowledge of the culture of the mulberry, or indeed of farming in general, other than that I have obtained from an occasional perusal of your valuable journal. Whilst sojourning at * * * * I picked up a number of your periodical to dispel an hour's dulness. I was soon interested; read each succeeding number with eagerness; became a convert to your opinion, that "more money, apart from the consideration of comfort and many other et ceteras, may be realized by a judicious system of farming in Virginia, than by the culture of sugar or cotton at the south;" changed my occupation and residence, and have now set down to attempt the realization of hopes which you have engendered."

—

Goochland, Va., September 10, 1838.

"Now that the tops are taken from the corn, a tolerable estimate may be formed of the product. On the James river low-grounds, not more than half a crop will be gathered; while on the high-lands there cannot be more than one-fourth. No person that I have seen, has expressed a more favorable opinion than this. But the deficiency is not owing entirely to the drought. The chinch bugs have infested the country in myriads; and their depredations have curtailed the crops of corn nearly or quite as much as the dry weather. Not a farm, as far as my observation extends, has escaped their ravages; in some places they have been so numerous as to utterly destroy whole acres, besides materially diminishing the product of the fields at large."

Lake Phelps, N. C., Sept. 11, 1838.

"I cultivate the rich, low swamp lands of North Carolina, and this is the thirty-fifth crop. I have never known it suffer so much from drought. I cannot get more than two-thirds of a crop. My crop of wheat was as good in quality and weight, except once, (1805,) as I ever raised; but fell far short in quantity, averaging only about eighteen bushels to the acre."

—

Montgomery Co., Md., Sept. 11th, 1838.

"There is a complete failure of every crop that is grown in my neighborhood, with the exception of wheat. Corn, tobacco, oats, and the whole list of culinary vegetables have fallen victims to the incessant, and yet unending drought of the past summer. The rye crop, though abundant in straw, yields little or no grain, and that very defective, in consequence of the heavy rains that fell in the month of May, when it was in blossom. I am fully convinced that there will be less grain made in our state this year, than there was last, when there was literally no wheat; and the crop, however good it may prove this, cannot make up the deficiency in the other crops."

—

Fluvanna, 20th Sept. 1838.

"The equinoctial spell was ushered in this morning, with great parade of thunder and lightning; but as yet, (12 o'clock,) very little rain has fallen, and the clouds seem light and hard, though the wind is at a rainy point, and the *season* must bring more. Several days and nights of such as we have had, would be required to start our mills, of which three can grind in a distance of thirty miles, and I believe no others within fifty. The rains that fell about ten days ago, were confined to the lower country. Here, there was a heavy *dew:* in Albemarle, not a drop. The dust in the stage-roads of that county, was, yesterday, above the horse's fetlocks, an impalpable powder, and threatening to suffocate man and beast."

—

On the 11th and 12th of September, there fell through eastern and part of middle Virginia, a most abundant rain. If too late to benefit the corn, it at least permitted the fallowing and ploughing of clover-ley for the next wheat crop to be commenced, in proper manner, though much too late. The rain did not extend to the upper country. The general inability to plough for wheat during the best season, and through the best clover and wheat region, must injuriously affect the wheat crops of 1839.

P. S. Sept. 25th and 26th.—Steady and abundant rain.—Ed. Far. Reg.

LATEST REPORT OF THE MULTICAULIS TRADE AND MANIA.

A late number of the Saturday Evening Post of Philadelphia, gives the following statement.

"The sales of mulberry trees have been very brisk for weeks past, even to the amount of several hundred thousand dollars. Many culturists who were disappointed in obtaining trees last year—or postponed purchasing on the ground that plants would be a drug and "as cheap as a broom" this year, have now taken "time by the forelock," and bought largely at higher prices than when they were "so very scarce and dear" six and nine months ago.

"The prices are so various, that it is nearly impossible to give exact estimates. Buyers say the price is 50 cents per tree—the sellers, that it is 75 cents.

"Within a few days trees have been offered at 15 cents, 17 cents, and 20 cents per foot, the root with one inch of stalk being counted as one of the feet, and some fine plants have been sold at $1, and $1.50 the tree. The general belief is, that nearly all the trees for sale within 40 miles of this city have been sold. The growers generally choosing to keep a large stock on hand for seed the ensuing season; and well they may like to continue propagating, for in many instances their profits have reached 1,000 per cent, while others who have not been so fortunate in their cultivation or soil, have netted 500 per cent. within the last six months."

A purchase has very lately been made of more than 20,000 young trees, untrimmed, from J. Atkinson, Esq., Pitt county, N. C., at 40 cents. Only a few of them are of the second year's growth, nearly the whole being from cuttings set out last spring, (1838.) But, as stated by the purchaser, the youngest trees are uncommonly fine, being nearly or quite 6 feet of average height; and some few of the youngest which grew on hog-pen ground, are nine feet high. These are strong evidences of the superior and remarkable fitness of the climate of the southern states for this valuable tree. It is now a matter of congratulation, that this large parcel is purchased for planting in North Carolina. The demand of purchasers from the northern market has been so great as to threaten to leave in the south but a small stock to plant next spring.

A gentleman who has a lot of multicaulis trees in Petersburg, has been offered, and refused to take $1 per tree, (untrimmed,) for all the trees of more than one season's growth. These plants are of the second and third season; but not having been taken care of, as to proper soil and culture, they are not six feet, average height, and of much less size than all ought to have in two seasons from the cuttings. Of some of the same original stock, (brought from the north when very small, and set out in spring of 1837,) but which have stood in rich land, a few entire plants have been sold at $5 a-piece. These were not the best. They had all been cut off near the ground last fall, and the whole of the present tops, (now 7 or 8 feet high,) are of this season's growth.

Contracts have recently been made here for some thousands of plants of the growth of 1839, untrimmed, and to be from 2 to 4½ feet high, to be delivered in the autumn of 1839, at 12½ cents the plant.

A friend has shown to us letters, just received in answer to his inquiries, from the owners of the most entensive nursery in New York, and another in Baltimore. The prices of both are copied below, not only for present information, but also for the admiration of the curious hereafter, when this mania shall have subsided.

The tariff of prices at which the New York establishment offers to sell, is as follows, for the plants, all the side-branches trimmed off.

Plants 1 to 2 feet high, - - - -	20 cents.
" 1 to 3 " " - - - -	25 "
" 1½ to 2 " " - - - -	22 "
" 1½ to 2½ " " - - - -	25 "
Plants 1½ to 3 feet high, - -	28 cents.
" 1½ to 3½ " " - - - -	31¼ "
" 1½ to 4 " " - - - -	35 "
" 2 to 4 " " - - - -	38 "
" 2 to 5 " " - - - -	45 "

The writer adds, that when the expected state bounty for silk is offered, that all the plants in the United States could not supply the demand in the state of New York alone.

The answer from the Baltimore nursery men, says, "We sold last week our entire crop at 22½ cents—50 and 60 cents per tree, without side branches."—"Cuttings with two eyes are now worth $60 per thousand."

A letter from another well-informed friend in Baltimore, dated September 22, states the recent sales between the speculators, have been at 10 cents the foot of length for trimmed plants, and 20 cents the foot for those not trimmed.

From the American Silk Grower.

MULTICAULIS PLANTS ON LONG ISLAND.

We are indebted to Wm. Kenrick, Esq. of Newton, Mass., who recently made us a visit, for some information concerning the mulberry prospects at the north and east. He informed us that his trees had prospered finely, and that he should have 100,000. On his way hither he called at the nursery of William Prince and Sons, on Long Island, and said that those gentlemen planted six acres of cuttings and three acres of trees. The trees had done well, but the cuttings had failed, or nearly so, as had all the cuttings that were planted on the island. He thought, however, that Prince and Sons might have 100,000, but not more. Why will gentlemen advertise ten times as many trees as they have growing? Will it not deceive and injure individuals and the public?

For the Farmers' Register.

ON SEEDLINGS OF CHINESE AND OTHER MULBERRIES.

In a late number of the Register, there are some editorial remarks to establish the fact, that seedlings of the morus multicaulis do not conform entirely with the characteristics of the parent. I have recently had an opportunity of making a careful examination of several multicaulis seedlings; and I can also certify, that, though there is a general family likeness, they are certainly different from their parent. At the same time, there is sufficient testimony to prove, that in some instances the resemblance is complete. Gideon B. Smith, of Baltimore, who is good authority on the subject, contends for their identity of character; and David Thomas, of New York, one of the most intelligent and scientific botanists in this country, assured me in the course of some remarks he made on the article "on agricultural humbugs," that he had several seedlings which were precisely like the original; and he had no doubt the multicaulis was a distinct species, and would produce its like.

It must now be admitted that the multicaulis will run into varieties; but does this prove that it is only a variety of itself? By no means. There is no species of mulberry that has been brought into general cultivation, that can be relied on to reproduce its exact likeness in all, or even in a majority of cases. Indeed, the whole family of *morus* seems disposed to be sportive; and the long course of culture to which they have been subjected, has contributed, as in the case of many other plants, to increase this propensity. Witness the rose and the dahlia, the varieties of which are endless, but which to this day would have retained all their original features, if they had been permitted to remain in their natural *habitats*.

I have recently examined a great number of seedlings of several species of mulberry. The varieties of the *morus alba* are endless, as is well known; and there is the same want of uniformity in the offspring of the Canton, the Alpine and the Brussa, respectively. In all these species there are a multitude of varieties which are totally worthless; and if the multicaulis was produced in the same manner and to the same extent, this character would doubtless apply to its offspring with the same force. But throughout all these diversities, a practised eye will, without any hesitation, assign each individual to its appropriate species. If the multicaulis could ever run into the white mulberry, there might be some reason for the belief that it was derived from that species. The white mulberry retains its glossy, brilliant foliage through all generations; and in the multitude of individuals which have derived their existence from it, none can be produced which a botanist could possibly mistake for the multicaulis. On the other hand, whatever shape the leaves of multicaulis seedlings may assume; however they may degenerate in size; it is equally out of the order of nature that they can ever take the specific marks of the white mulberry.

A most curious and remarkable instance of the sportive tendency of the white mulberry, may be seen at John Carter's nursery, near Richmond. The individual was originated on his grounds, near to where the *multicaulis* and the *alba* had both fruited; and different as it is in some respects, from any other mulberry plant which has come under my observation, yet its parentage is sufficiently obvious. I cannot concur with the originator, that it is a hybrid. In its growth it is rather dwarfish—the joints of the branches are not more than the fourth of an inch apart—the leaves are about five times as large as the white mulberry leaf,* but in shape and character very much resembling it; and upon each branch there is such a dense mass of foliage as entirely to exclude the stem from observation. It deserves to be propagated as a curiosity—or rather as a monstrosity.

TUCKAHOE.

From the Quarterly Journal of Agriculture.

USEFUL INSTRUCTIONS REGARDING THE MILKING OF COWS.

The operation of milking is performed differently in various parts of the country. In some, the dairy maid dips her hand into a little milk, and by successively stripping the teat between the finger and thumb, unloads the udder. The plan, however, is attended with the disadvantage of irritating more or less the teat, and rendering it liable to cracks and chaps, which are followed by inflammation, extending to the rest of the quarter. This accounts for the disease occurring more frequently among the cows under the charge of one milker than it does in those which are under the charge of another; and, as this practice is more common in some parts of the country than in others, it also accounts for the disease being more common in these parts. This plan of milking, where the irritation is not sufficient to excite the extent of inflammation to which I have alluded, frequently produces a horny thickening of the teat, a consequence of the cracks and chaps, which renders it more difficult to milk than when in its natural state; and at the same time predisposes to inflammation, when any case occurs to set it up. These effects may be, and are almost entirely avoided, by the more scientific plan of milking adopted in other parts of the country, where, instead of drawing down or stripping the teat between the thumb and fingers, the dairy maid follows more closely the principles which instinct has taught the calf. (The calf jerks its nose into the udder and forces down the milk.) She first takes a slight hold of the teat with her hand, by which she merely encircles it, then lifts her hand up, so as to press the body of the udder upwards, by which the milk escapes into the teat, or if (as is the case when some hours have elapsed between milking times) the teat is full, she grasps the teat close to its origin with her thumb and fore-finger, so as to prevent the milk which is in the teat from escaping upwards; then making the rest of the fingers to close from above downwards in succession, forces out what milk may be contained in the teat through the opening of it. The hand is again pressed up and closed as before, and thus by repeating this action, the udder is completely emptied, without that coarse tugging and tearing of the teat which is so apt to produce disease.

From the Farmers' Cabinet.

BROKEN LIMBS OF ANIMALS.

An idea prevails with many persons, that broken limbs of horses and other quadrupeds cannot be cured, owing to the difficulty of keeping the part sufficiently at rest during the time necessary for a broken bone to heal or acquire sufficient strength to support its share of the animal's weight.

I heard of a case, some months since, which was successfully treated in the following manner, viz: two pieces of scantling sufficiently strong to support the horse were placed over and parallel with him in the stable; a piece of strong linen was then passed under him and the two opposite ends confined to the scantling so as to raise him from the ground or floor when required: a wooden box was provided with a bottom, two sides, and one end, composed of boards nailed together, and of sufficient length, width, and depth, to contain the leg from the knee to the foot, inclusive, besides a space of half an inch or more, on each side of the leg to admit the necessary bandages, &c., with the bottom cut away sufficiently for the foot to enter and retain its natural relative position with the leg. The broken leg was confined in this box, and treated in the usual manner that bones are when broken, and the box together with the leg from the knee to the foot confined in a horizontal position or nearly so, by straps of leather or other suitable substances passed over the horse's back and the two ends confined to the box; the horse was permitted to put his other three feet upon the floor sufficiently to preserve a healthy action to the limbs, but not so as to permit him to displace the broken limb in the box and injure it. A cure was effected in the course of a few weeks. This was one of the anterior (or fore) legs. I see no difficulty in treating a hind leg by partially suspending the animal in this manner, and varying the other parts according to the particular nature of the case. Z.

Chester county, Pa., June, 1837.

NEW BRANCH OF THE RICHMOND AND FREDERICKSBURG RAILWAY.

We understand, that the new rail-road, (about three and a half miles long, to connect the Deep Run Coal Pits with the Fredericksburg and Richmond rail-road,) was opened on Wednesday last. The road is said to be admirably constructed. The field of coal in that region is very extensive. Several shafts are about to be sunk; and the enterprising Mr. Barr has already 150,000 bushels raised. This branch road has been constructed by the proprietors of the mines; and they are entitled to the privilege of bringing their coal down the main stem to Richmond, free of toll. When the road shall have thus been paid for, it will be transferred to the Fredericksburg and Richmond rail-road company.—[*Rich. Enquirer.*

MONTHLY COMMERCIAL REPORT.

The most important feature in the transactions of the present month, is the great advance in the price of grain. Inadequate supplies of wheat for the daily demand of the millers, first gave an impulse to the market; but accounts from England to the 10th August, by which it appears that while this country was oppressed with heat and drought, the very reverse prevailed there, and apprehensions were entertained of entensive injury to the grain crops, created great excitement in all markets. Prices advanced rapidly in England, and were expected to attain, in a few weeks, to the maximum average of 73 shillings per quarter, (of 560 pounds of wheat,) at which foreign grain is admitted almost duty free. Accounts to the 8th of this month, daily expected by the steam-packet, will, in a great measure, decide the question, as to the English crops. In Holland, also, the weather was unfavorable, and the stocks of old grain in the north of Europe were unusually small. The price of wheat consequently advanced in our markets until it reached $1 70 to $1 75 in Richmond, $1 85 to $1 97 in Petersburg, and $1 50 to $2 00 in the northern cities, where there is a greater diversity of quality. Some shipments of flour have already been made to Liverpool from New York and Philadelphia, at $9 00 per barrel. These may, perhaps, be considered rather precipitate, as the result of the crop is yet doubtful—a few days will decide it.

There have been sufficient rains below the falls of the rivers to revive vegetation; but higher up the country, they have as yet, (22d September,) been so moderate, that the water courses are not filled. Few of the country mills could grind, and interior navigation has been in a great measure suspended. The same state of things has prevailed to the north and west; so that supplies of grain and flour, which are represented as very abundant in the western states, will be moderate from thence until next spring. Corn has advanced to 95 to 100 cents per bushel. In the lower part of North Carolina, and in some of the lower counties in Virginia, the crop is said to prove better than had been anticipated; but, in the upper country, very deficient. The price of bacon has gone up to 16 to 17 cents.

The weather, for some days past, has been favorable for tobacco; but "*the stand*," (as the planters term it,) was so small, and the season is now so far advanced, that there is no doubt the crop will prove very short, even with a continuance of favorable weather; and, should there be a frost soon, a large portion of the crop will be destroyed. This article has attained to high prices: $6 50 to $13 60, embrace the extremes, except for a fancy article. The export to Europe has been moderate, as are the stocks on hand compared with former years.

The receipts of cotton, during the month past, have been very light. The quantity received in all our ports, since 1st October last, is now stated to be 1,808,000 bales, against 1,360,000, in 1837. The export, 1,580,000 against 1,155,000. Prices have been sustained, better than could be expected, under so heavy a supply. In this market, 10 to 11 cents is now quoted. A few hundred bales of the new crop, received at New Orleans, and represented as very fine, commanded $12\frac{1}{2}$ to $13\frac{1}{2}$ cents, while the quotation of old is 7 to 11 cents. The crops in Louisiana, Mississippi, South Alabama and Arkansas, are stated to be fine and abundant. From other quarters, the accounts vary. In North Carolina and Virginia, the crop is undoubtedly very short.

Exchange on England has recently been at $9\frac{1}{2}$ to 10 per cent. premium; but the importation of grain into Great Britain will tend to reduce the rate between that and other countries, to cause an exportation of specie, and to advance the rate of interest in England. X.

September 22, 1838.

P. S. *Sept.* 27.—The steamer, Great Western, has arrived at New York from Bristol, whence she sailed on the 8th inst. The weather in England had been generally favorable for harvesting, since the advices previously received; and there was some depression in the prices of grain. The average of the preceding six weeks, had, however, reached 72 shilings and 11 pence, or within one penny of the rate for admitting bonded wheat, at the duty of one shilling per quarter.—There would, therefore, be a very large quantity, (not less than a million of quarters) entered for home use, which would tend to reduce the price. This news has caused a slight decline here. In the prices of cotton and tobacco, there was little variation.

NOTICES AND REPLIES TO CORRESPONDENTS.

There is no authorised general agent or collector for the Farmers' Register IN VIRGINIA; nor will any be appointed soon, nor without notice being published. Some of the reasons for this departure from general usage, were stated at page 127, No. 2, of this volume, to which those who have made inquiries are referred.

There being no agent to receive payments is no impediment to these being made, whether by new or by old subscribers. In either case, if money is sent through a post-master's hands, or evidence is taken of a letter containing money, and properly directed to the editor, being committed to a post-office, the loss is the editor's, and the proper credits will be allowed, and the copies sent, upon information of the transmission, though the money may not have been received. (See the conditions of Farmers' Register.)

The notes of all specie-paying banks will now be received for subscriptions to the Farmers' Register. The banks having generally resumed specie payments, it is hoped that much of the inconvenience suffered by subscribers, and of heavy pecuniary loss by the proprietor, during the time of suspension of payments, may hereafter be avoided.

"A subscriber," whose letter was received through the post office too late in last month to be answered, is requested to refer to and read the "Address to the friends and supporters of the Farmers' Register," at page 63, No. 1. of this volume, for the explanations and reasons which he deemed wanting.

The author of the anonymous communication from the north, (accompanied by a private note signed, *as was then supposed*, by a real and responsible name,) containing serious charges against a large and noted seller of mulberry plants, is informed that it will not be published in the Farmers' Register, until sustained by known and undoubted authority. Our pages will always be open to well established statements, *from responsible sources*, of any of the numerous impositions practised upon the agricultural public.

Vol. VI. NOVEMBER 1, 1838. No. 8.

EDMUND RUFFIN, EDITOR AND PROPRIETOR.

THE ACTUAL STATE OF SILK CULTURE IN THE NORTH, AND REMARKS ON ITS EXTENSION IN THE SOUTH.

To the Editor of the Farmers' Register.

Some years past, I have been endeavoring to collect all the information that was accessible on the subject of the silk-culture, with the view of engaging in it as soon as opportunity should offer. And during the past summer I made a visit to some of the northern states, for the purpose of more fully satisfying myself, by personal observation; and to see with my own eyes what was doing there, that might justify the glowing accounts that were published in the agricultural papers. It is now my intention to give, in as fair and impartial a manner as I am capable of doing, the results of my observations; interspersed with such remarks and reflections as they have suggested.

In these times, when so much is done for effect, and when every new enterprise is ushered before the public with so much pomp and circumstance, it is natural that the sanguine should be easily led astray, and come readily to indulge in all the extravagances which characterize the projectors of novel schemes. In regard to silk-culture, though I am perfectly convinced that it will be both practicable and profitable, and that its introduction into this country will become, or ought to become, a general thing at no very distant day; yet considering the progress that has been actually made, and the little that has been accomplished, the wildest calculations have been made of its profits; theory has run far ahead of practice; and very few of those who make such extravagant boastings have tested its real advantages by experiment.

Some years ago, when the subject was first agitated with so much earnestness, a number of incorporated companies with large capitals were established in the eastern states. The most of these have now an existence only in name. Some of the most prominent of them, by attempting too much, and by combining the manufacture with the production of silk, have entirely sunk their means. Others have failed to make any dividends, through the incompetency of agents, or in consequence of the high salaries that were allowed them. Others again, and perhaps all, in a measure, have transferred their zeal from the legitimate object of their establishment, to the tempting allurements held out by the high prices of mulberry trees; and not one, as far as my information extends, has done any thing towards extending the knowledge of the silk-culture amongst the people at large, or made any attempts to introduce improvements in the management of the worms, and in the art of reeling and preparing silk. In the excess of their early zeal, the natural order of things was reversed. Lands were provided, buildings and fixtures erected, before there was any food for the sustenance of the worm. Having begun at the wrong end, and been then diverted by other considerations from carrying out the original object of their design, they have failed to answer the purposes contemplated by their formation.

Whoever therefore, depending on the ostentatious parade with which silk companies have been introduced to the admiring gaze of the readers of silk and agricultural papers, visits New England or elsewhere, with the expectation of seeing the silk culture carried on by them, and of deriving the necessary information from them for his own guidance, cannot fail to be disappointed. He must go to private individuals for instruction; he must get access into families, engaged in feeding worms, and observe their practices and management. It is amongst them only that any thing has been done, or from whom any thing can be reasonably expected. The silk business, in its present state of infancy, will not justify a large outlay, with a view to carrying it on to advantage. And especially is it necessary to consult economy in those places where the white mulberry is depended on as food for the worms. There is not, at present, skill enough in the country to justify the employment of agents, except under the immediate control of the person interested, to superintend the feeding of a large number of worms. When the business shall have been perfected in families, and the process of making silk shall have become generally understood, so that given means may be relied on to effect given results, operations may be extended to a larger scale with greater prospect of success.

At Northampton I expected to see greater progress made in the silk culture than at any other place in the United States. It has claimed for itself the merit of being the pioneer in the great work. For years the Northampton paper has been applauding the efforts that have been making to introduce and extend it. We were led to believe that it was the head-quarters of the silk business—the fountain from which instruction was to flow like a stream, to gladden and enrich the whole country. A great silk company, styled *par excellence*, the "New York Silk Company," was established there at an early date—a large capital was subscribed—a farm of several hundred acres was purchased at a great price—upwards of one hundred acres were planted in mulberries of one kind or other—a large factory was erected at considerable expense—and there the work terminated. The farm is now offered for sale; and the operations of the company are to be confined in future to the factory. Not a pound of silk, as far as I was informed, has ever been produced by the company. Glowing accounts have also been given of a silk company at Norwich, in Connecticut. Before leaving Virginia, I had been advised to take that place in my route, and was informed that silk would be produced there this year, not by pounds, or by hundreds of pounds, but by thousands! During the time I remained in New England, I made diligent inquiries about Norwich, and could not learn that any thing was in progress there that would instruct or interest a visiter. These examples are given as a fair illustration of what has been performed by incorporated companies. At Northampton, however, we are promised better things for the future; and something has been done during the past season, both in the village and in the neighborhood, in the way of feeding worms. I saw one cocoonery, in which perhaps fifty thousand worms had just completed their labors; and another, erected on a large scale, in which nearly a million of eggs were in the act of being hatched. But there was a great scarcity of food; and liberal prices had to be offered to the owners of such plantations as were situated in the vicinity of the village, for whatever amount of foliage they could supply. So great has been the trade at Northampton, in mulberry trees, that out of the hundreds of thousands of seedlings which have been grown there within the last few years, the number of those planted expressly for feeding worms is very inconsiderable. Perhaps no place has dealt more largely in the article; and the practice of selling off so close as to leave none for feeding worms, has been the subject of considerable censure. A reformation has been promised in this respect; and I was assured by a prominent and enterprising culturist, that he was determined hereafter to retain the greater part of his trees for permanent plantations on his own grounds. Should he devote his energies to the silk culture, I know of none whose intelligence and qualifications are better calculated to insure success.

It is not my intention to charge either individuals or associations with a design to delude the public. On the contrary, I have no doubt that most of them were influenced by as correct motives, in advocating the adoption of the silk-culture, as generally govern the actions of men, willing to instruct others and promote their interests at the same time that they can do it with advantage to themselves. Neither do I believe that the silk culture is intended or expected to turn out a mere delusion. If companies have failed, individuals have been eminently successful; in a smaller way, it is true, but on a scale large enough to prove that the culture is both practicable and advantageous. A number of instances might be adduced to establish the fact that worms may be fed in this country, and carried through their various ages in perfect health; that the climate is admirably adapted to their welfare; and that silk of the best quality may be readily produced. The reason, therefore, that so little actual progress has been made, considering the much that has been said and written, and the great degree of public attention and even excitement that has been elicited in its behalf, is to be found in causes sufficiently obvious, and which have already been adverted to. The wonderful demand for the *morus multicaulis* and other valuable species of the mulberry, renders the cultivation of these plants the most profitable agricultural occupation that ever was followed in this country. A greater profit is to be derived from a few acres of land under this culture, than from large fields of wheat or corn, or even cotton or tobacco. As long as men will consult their interest, it is not to be supposed that the slow and tedious process of rearing silk-worms and reeling silk, however profitable it may be, compared with most other agricultural pursuits, will be prosecuted with full vigor, while the profit to be derived from the sale of the plant which constitutes the food of the worm, transcends in value that of the silk to be derived from it. While the demand for the mulberry continues to be extensive, and the prices high, it will be idle to expect that silk will be produced in large quantities. But in a few years, when the country comes to be well stocked, and the prices decline so much that sales can with difficulty be effected, a new state of things may be anticipated. There will then be no other resource but to appropriate the mulberry to its legitimate use; the community at large will be compelled by the force of circumstances to engage in the culture of silk, and we may then expect to see the business extensively flourish. In the mean time, the experiments that are making will lead to improvements in the management of the worm; every year will be adding something to the stock of knowledge, and contributing to ultimate success. The mulberry will shortly be in the possession of every family, or readily accessible to all; and no longer, as at present, capable of being monopolized by speculators, who having no interest in the establishment of the silk culture farther than to supply the plants, and never intending to follow it as a branch of industry, are intent only on deriving a heavy profit from them.

I am not one of those that object to seeing the mulberry sell at fair prices. If there was no demand for them, all attempts to extend the silk culture would fail. But I do object to making the mulberry culture and silk culture two distinct branches of business; and, above all, to the practice which many persons follow, of calling themselves *silk-culturists*, when they are only speculators in the plants, or growers of them for the market. None talk more largely of the benefits of making this a silk-growing country—none discourse more eloquently on the advantages to be derived from adopting the culture—while the main object is to create a demand for their trees. The press teems with "silk-growers' guides," and other publications, from the fertile pens of mulberry growers, demonstrating in glowing language the enormous profits of the silk culture. It would be desirable if public opinion could be brought to bear upon such persons, and compel them—a reasonable compulsion it would be—to appropriate some of their profits to the construction of cocooneries, in order to prove to those whom they are persuading to purchase, that silk may be profitably produced; and give them ocular demonstration that their trees are worth what is demanded for them. By this mode, the sale of trees might not be diminished; it would probably be promoted; but at the same time, every person would purchase with a knowledge of what he was doing; and the trees would fall into the hands of those who would endeavor to convert a portion of them into silk. Had this system been pursued, and light shed amongst the people, even the present high prices for the mulberry might not be above their value: at any rates, the demand would not be a factitious one. It is in truth a most valuable plant, if the silk culture is practicable, and deserving of higher appreciation, from the fact that it is reproduced with so much facility. Although the actual cost and labor of propagation are inconsiderable, yet its intrinsic merits so far surpass those of any other mulberry, that for an outlay of five dollars, a stock of plants may be obtained, in four or five years, capable of sustaining millions of worms. It would therefore be better to give even a dollar a piece for a few plants, than to give a dollar a thousand for the old white mulberry, which would only be fit to feed from, at six years of age, with a scanty supply of foliage, and difficult to gather, even then.

It is generally considered that the multicaulis is the most valuable mulberry in the country. In the southern states, and as far north as to New York, and even in some parts of New England, it flourishes with great luxuriance; and the roots, and even branches for the most part, will withstand the winters without material injury. But for the more northern portions of the United States, it is extremely doubtful whether it can ever be cultivated to advantage. It is certain that in the neighborhoods of Albany and Northampton, its growth is stunted; but local causes exist to render those places colder than any others in the same parallel of latitude. The soil for a considerable distance round them is so light and sandy, that it parts rapidly with its heat whenever the rays of the sun are withdrawn or excluded. For the northern and eastern states, however, there are other species of the mulberry more hardy than the *multicaulis*, of a rapid and vigorous growth, and furnishing leaves of a large size and in great abundance. Distinguished cultivators there have their particular favorites. The Alpine was introduced and is patronized by Saml. Whitmarsh, the Canton by Dr. Stebbins, and the Brussa by some gentlemen of Albany.* At Northampton, there is such a confusion of names, that persons residing at a distance have very little idea of what their mulberries really are. Instead of being designated in such a manner as to be readily distinguished from all others, the specific term of *multicaulis* is applied to species entirely distinct, as well from each other as from the multicaulis proper. Thus the Alpine is called the *morus multicaulis Alpinense;* and the Canton, the *Canton multicaulis.* Both the Alpine and Canton have sufficient merits of their own to enable them to stand without any extrinsic aid; and the appropriation of terms to which a definite idea has been long attached, is calculated to mislead and produce a false impression. The Alpine is only known as having been brought from the foot of the Alps, where it was called the *Chinese mulberry*, and is the same kind for which, under this cognomen, the gentleman that introduced it was made the object of so much obloquy a few years ago. The odium that was cast on him then, was, as I am now convinced, very undeserved. The merits of the controversy turned on a name; and that name appears to have been inadvertently adopted, or rather continued in conformity with the designation of the species in Italy, and not with the intention of passing it off as the genuine multicaulis. The effect, however, has been to impair his usefulness ever since.

If the silk culture has not advanced with the rapid strides, in the states where it received its first impulse, which were predicted of it; yet it has made some progress in other places, where it has been recently introduced. A much larger number of worms has been fed during the past season than has ever been fed in one year before; and complete success, as far as I had the opportunity of observing or ascertaining, attended the management of them. In New Jersey, Pennsylvania and Delaware, and on the Eastern Shore of Maryland, much more has been done than in any other parts of the country. A considerable stimulus has been given to the business, in some of those states, by the liberal bounties upon silk produced within their respective limits. A large proportion of the late crop of cocoons was reserved for eggs for another year; and even now the demand for eggs is almost as great as that for mulberries. The experience of this year has satisfactorily proved that even from trees, the growth of cuttings and layers planted in the spring, worms may be advantageously fed the ensuing summer. It is only necessary to retard the hatching of the eggs by placing them in an ice-house, which should be done before the warm weather in the spring comes on. By this means, they have been kept till midsummer. Under any circumstances, the hatching may very properly be delayed till the early part of June, which is probably as soon as worms should be brought out even in Virginia. The cold, wet weather of May, which is frequently a disastrous period to the young worms, is thereby avoided; and the natural time of hatching is only postponed about three weeks. Whether they can, for a number of years, consistently with the health of the insect, be prevented from hatching until the latter part of July, may be regarded as doubtful. The practice is so contrary to nature, that it will not be at all surprising if the effect should prove unfavorable. Neither would any necessity exist for it, if the culturist would reserve a small number of standard trees or roots, and make use of the two-crop worm for his second and third crops.

I have no information which would enable me to state with precision the quantity of silk that may be produced from an acre of ground. During the past season, one gentleman in New Jersey obtained from the sixteenth of an acre, a product at the rate of 56 pounds per acre, from trees of the first year's growth. Had the trees been a year older, the quantity of silk would no doubt have been fully doubled; and might have been still further increased by successive crops. The cocoons of this year were almost invariably firm and heavy; and I heard of no worms that fed longer than twenty-eight or twenty-nine days; the usual period of their lives being thirty-five days. This abridgment of the ordinary term of their existence, is to be ascribed to the high temperature of the summer; for we know that, under different circumstances, it is sometimes prolonged to forty days. The past season, hot and dry as it was, appears to have been very favorable to the health of the worms. I heard, on respectable authority, that a culturist in Delaware had fed 150,000 with a loss of not more than twenty. Among all that I saw, some of which were a good deal crowded, I observed no symptoms of disease, and heard of none prevailing elsewhere. One or two facts that came within my knowledge, showed that much care is requisite in the treatment of eggs when the hatching is to be postponed. It is acknowledged by all, that it is important to keep them dry; and to guard against the least admission of moisture, some persons put them in bottles and seal them air-tight. Whenever the eggs remained in this condition for any length of time, their vitality was entirely destroyed; while others of the same parcels, but treated with less care, hatched without loss.

* Charles Rhind, Esq., formerly minister at Constantinople, introduced the Brussa mulberry. See his communication to the Farmers' Register, page 55, vol. V.—Ed.

Without intending to make any invidious comparisons, and premising that there were many places where the silk culture was said to be thriving, which I did not visit, I have no hesitation in saying that there was more doing at Burlington, New Jersey, considering how recently the business has been started there, than at any other place which came under my observation. A considerable number of persons were engaged in feeding worms as well as in raising trees. A few extensive cocooneries had been erected, one of which was large enough to accommodate about a million of worms; and several others from one to two or three hundred thousand. The soil in the vicinity of Burlington, is light and sandy, and well adapted to the growth of the multicaulis. Indeed the greater part of New Jersey is admirably suited to the purpose; and the business is so rapidly spreading, that in a few years, that state will probably be much in advance of any other. Within a few years the improvements in the construction of cocooneries, have contributed greatly to the facility of feeding worms. The plan of those at Burlington, struck me as being rather superior to any I saw elsewhere. The necessity of handling the worms is entirely dispensed with by the use of hurdles of net-work; at the same time that the cleansing of the shelves and the removal of the litter are more easily effected. When it is time to change them, another hurdle is laid on the one containing the worms, and fresh leaves are sprinkled over it, which are always cut up by running them through a cylindrical cutting box. In a few hours, the worms attracted by the fresh leaves, get on the upper hurdle, when the lower one, containing the litter, is removed. In this manner, a large number of worms may be cleansed in a day, by providing extra hurdles. A better fixture for the accommodation of the worms in spinning, has been latterly introduced. On the lower side of the shelf immediately above, which is not more than twelve or fourteen inches distant, strips or laths, about two inches wide and three inches from each other, are fastened at right angles to the range of shelves, to which the worms mount by very simple ladders, and spin their balls along the junction of the strips and floor. This mode adds greatly to the convenience of gathering the cocoons, and the floss is removed from them free of the litter which attends the use of brush or dried leaves. A room thirty feet wide will admit of four ranges of shelves, three feet wide, leaving an aisle between each range, and also between the outer ranges and the walls, of three and a half feet. The number of shelves in each range will be in proportion to the pitch of the room; say six shelves for a room, nine or ten feet high. Each hurdle is three by four feet, and will accommodate a thousand full-grown worms. On this plan, a room of a hundred feet in length by thirty feet in width, with a pitch of nine or ten feet, will accommodate, without crowding, about half a million of worms at a time. But in a cocoonery, near Frankford, in Pennsylvania, which was not of much more than half these dimensions, six or seven hundred thousand worms were fed in June last, which spun well. They were, however, evidently too much crowded, as was shown by the small size of the cocoons; and had not the season been of the most favorable character, the whole brood would have been in danger of being swept off by an epidemic. In a small room at New Haven, in a house occupied by a Frenchman, which did not exceed ten feet square, he had successfully fed forty thousand worms, without the appearance of any disease amongst them. I saw a number of the cocoons, which were large and firm.

Many persons have amused themselves, and the public too, by making calculations of the great profits of the silk culture. It may be no difficult matter to state with tolerable certainty how many good cocoons will yield a pound of silk; but I think an error has been frequently committed by estimating the product *per acre*. Of mulberry leaves, as well as every thing else, the crop will be very variable, and depend on the quality of the land. If worms can be preserved exempt from disease, and good cocoons can be obtained from them, the number that an acre of ground will support, at the usual prices of land in our country, is a matter of very subordinate interest. It is only important when land is worth from one hundred to three hundred dollars per acre. When the value does not exceed five or ten dollars, as is the case with most of our lands, it is better to estimate the profits of the culture by the number of worms that may be fed, than by the quantity of land that it will require to supply them.

While so much is doing in some of the states to the north of us, for the advancement of the silk-culture, scarcely any thing has yet been attempted in Virginia. The attention, however, of some individuals, has been directed to the subject; and an interesting experiment in feeding worms has recently been detailed in the 'Farmers' Register,' by a gentleman of Brunswick. A very large cocoonery has been fitted up at Fredericksburg, which will probably be filled with worms next year. Other gentlemen are making arrangements to enter upon the culture. During the ensuing season, it is hoped that interesting results may be established by various persons. But, unfortunately, almost every tree grown in Virginia and North Carolina, with the exception of those retained to propagate from another year, has been bought up, and will be taken to Pennsylvania or New Jersey. The Virginia and Carolina trees have a decided superiority in the northern markets, and are sought after with avidity; a fact of which the cultivators here are perhaps ignorant. Southern trees are mostly produced from cuttings, while those of northern growth are raised from what are called *layers*—that is to say, a whole plant, both root and stem, is laid horizontally in a furrow, and covered over with earth. The young shoots sprout up so thickly that they make a spindling growth. Plants from cuttings, on the contrary, having more distance, throw out a number of side branches, and furnish a much greater supply of wood, which, besides that it is better matured by our southern sun, adds considerably to the market value. It would be desirable to know what number of trees have been grown in these two states during the present season. It will probably not fall much short of half a million; and next year, the number will no doubt be two or three times as many. But as long as we send them abroad, we are doing nothing towards the advancement of the silk-culture in our own state. And if there be any state in the union that would be more benefited by the introduction of this culture, allowing it to be, as is contended, both practicable and profitable, or whose soil and climate are better adapted to it, or where it can be prosecuted with greater economy in reference to labor, I should be at a loss to point it out. We occupy that position in regard to climate, which is too far north to admit of ours being a planting state; and too much to the south to be a first rate grain-growing or grass-growing country. We have extensive tracts of impoverished land in which the mulberry will flourish without difficulty, and where nothing else will grow. Our dry and long continued summers are eminently favorable to the health and prosperity even of successive crops of the silk-worm. We have in almost every family a number of unprofitable hands, either too young or too old to be put to constant employment; and the more intelligent portion of our colored population, remarkable as they are for their tractableness and powers of imitation, would soon learn to conduct all the operations of the cocoonery with neatness and skill.

Many of the states to the north of us have encouraged the introduction of the silk culture by legislative bounties; and I am convinced the wisdom of this policy will be justified in due course of time. If from causes already pointed out, but little has yet been accomplished in the production of the article thus encouraged, yet the ground-work has been laid, and the superstructure will be erected upon it. The seed has been sown, which will produce, some ten, some twenty, and some possibly a hundred-fold. It will, however, necessarily be a work of time. It may be another generation, and yet another perhaps, before it is established on a durable basis. But with a climate like ours, and with a species of mulberry superior to any hitherto known, the energies of the Anglo-Saxon race will eventually command success. The mental resources, the quickness of perception, the determined perseverance, which constitute the distinguishing attributes of this people, will enable them to triumph over every difficulty, and achieve all but impossibilities.

THE CROW (OR DAW?) A BIRD OF PREY.

Surry, Sept. 12, 1838.

A few weeks ago, whilst I was at a gentleman's house of this county, I witnessed an act in a crow, (the corn-dealer,) which was entirely new to me, and it may be so to some of your subscribers.

My friend and myself had been noticing his flock of young turkeys, then about a week old. He was complaining of the depredation and havock the crows were playing among them, saying that he expected to raise not one out of the whole. This excited much surprise, and induced me to watch for, and to notice the movements of, the crows. Whilst talking about them, or in a very few moments afterwards, there came one, (and crow he certainly was,) and immediately attacked the young brood, and after one or two unsuccessful efforts he succeeded in taking up one, in spite of every attempt of defence of the mother hen, and bore it off, in every respect similar to the hawk. It may be said, that this was a jack-daw, a smaller, and a different bird from a crow, as some contend. I, as well as my friend above, believe them to be one and the same bird. But whether crow or daw, it is immaterial; it was one of that family, and one of a large and full size.

By your reader, D. S.

From the Farmers' Cabinet.

A TRIP TO MARYLAND.

We passed over the bridge at Wilmington, into the rich alluvial bottoms of the Christiana creek, which extends nearly a mile from the city. The causeway is hemmed with two rows of beautiful trees, and surrounded with luxuriant pasture-grounds, that have, within these few years, been very considerably cultivated and improved. The high-land immediately connecting those rich bottoms, is gravelly and poor, but the immense amount of manure produced by the marshes, enables the farmer to force vegetation in every corner of his farm, and thus make his habitation a place of comfort and plenty.

The land through New Castle county is tolerably well improved; much of it is under cultivation, and the crops of wheat look well and bid fair to produce at least an average quantity; oats and corn not forward enough to form any opinion.

In Maryland, where the ruinous three-field system of farming prevails, the wheat looks bad enough to alarm one with the fear of want, notwithstanding some of her most intelligent citizens are inclined to the opinion, that the prospect is in favor of a medium crop.

As we advance towards the table-land that divides the waters which flow into the Delaware and Chesapeake, we find a kind of soil perhaps the most congenial to the growth of wheat of any in the United States, and why it is not a subject of deeper interest to the inhabitants of Pennsylvania, particularly to the enterprising citizens of Chester and Delaware counties, is a matter of some surprise.

In Chestertown we found land selling at five dollars per acre, and shell lime at six cents per bushel, neither of which seemed to excite any anxiety among the farmers, though the land was about a mile from the wharf, and the wharf within a few hours' sailing of the city of Baltimore.

On many of the farms upon the Eastern Shore, there are immense beds of shells spread over acres of land, and in some places six or seven feet deep, in a perfectly sound state, yet covered with mould, perhaps the growth and decomposition of grass and trees for many a century. A white oak that measured fifteen feet in circumference, had once reared his lofty head over those banks, but was now prostrate in a wilderness of underwood, with his tangled roots jammed full of shells, and most of them without any appearance of ever having touched the earth. Shells make the purest and best of lime; by a chemical analysis, it is found to contain little or none of those foreign substances that constitute from twenty to thirty, and in some cases, as much as forty-five per cent. of stone lime.

Shell lime can be had on the Eastern Shore at a very small expense, compared with what a Pennsylvania farmer pays for stone lime, even if he should be so fortunate as to have a limestone quarry upon his farm; and yet such is the desponding condition of agriculture in this country, that little or no attention is paid to the subject.

We visited Wharton Point, a high bluff of rolling-land that projects some distance into the Chesapeake, and forms rather a pleasant prospect of land and water scenery; but what was far more interesting, were the beds of shells which cover a space perhaps of fifty acres from one to six feet deep.

This property lies nearly opposite the mouth of the Susquehanna, which is constantly disgorging great quantities of all kinds of drift wood upon the shore. With this wood they burn the shell lime at an expense of about two cents per bushel.

The proprietors of this estate live in Delaware, and are making efforts to introduce the Pennsylvania mode of farming into the neighborhood; they have now on hand thirty-thousand bushels of shell lime, which is to be drawn out this season and spread at the rate of one hundred bushels to the acre for the next year's crop. We had taken with us small quantities of ruta baga, mangel wurtzel, and sugar beet' seed, and here we found a person willing to prepare a piece of ground to try the experiment of root-culture with the siftings or dust from the shells as a manure. We likewise engaged him to make an experiment upon an acre of poor land in raising of wheat. We directed him to turn the land down with the plough, spread upon it one hundred bushels of shell lime, sow it with three bushels of oats; when the oats had grown up and was beginning to change its color, roll it down, plough it in and sow the ground with two bushels of corn broad cast; about the second week in October, roll the corn down, plough it in and sow the ground with wheat. To give this experiment a fair trial, the oats should have been sown in the early part of the fourth month.

I am inclined to the opinion that the above plan would make the principal part of Delaware and Maryland produce twenty bushels of wheat to the acre, which, at $1.50 per bushel, would buy the land and pay all expenses of lime, seed and labor, and if laid down with clover, would, for a succession of years, produce good crops of hay and pasture. Such an investment of idle money would be more profitable than shaving notes at two per cent. a month, besides the additional security of real estate, and the satisfaction every generous mind must feel in the reflection that his labor has made two blades of grass grow where but one grew before. This peninsula possesses local advantages that few places in our country can boast. A soil peculiarly adapted to raising of grain, one that is easily improved and very difficult to wear out. It is watered with such a number of creeks, outlets and bays, that many of their farms are bounded by navigable streams, and very few indeed that lie further than five or six miles from a landing where abundance of lime and plaster can be had at reasonable prices, stone lime from the Schuylkill sells from sixteen to twenty cents per bushel, and shell lime at about half the price.

While so many are enamoured with the "far west," parting with their friends, their homes, and their fire-sides, for a prospect of buying land cheap, and being independent, for $1.25 per acre, could here buy hundreds of acres for less than nothing, compared with the wild lands of the west, and that too within a day's journey of three of the largest cities in the Union. I say less than nothing, for such is the depressed state of agriculture in the peninsula, that farms are often sold for less than the buildings, fences and other improvements have cost.

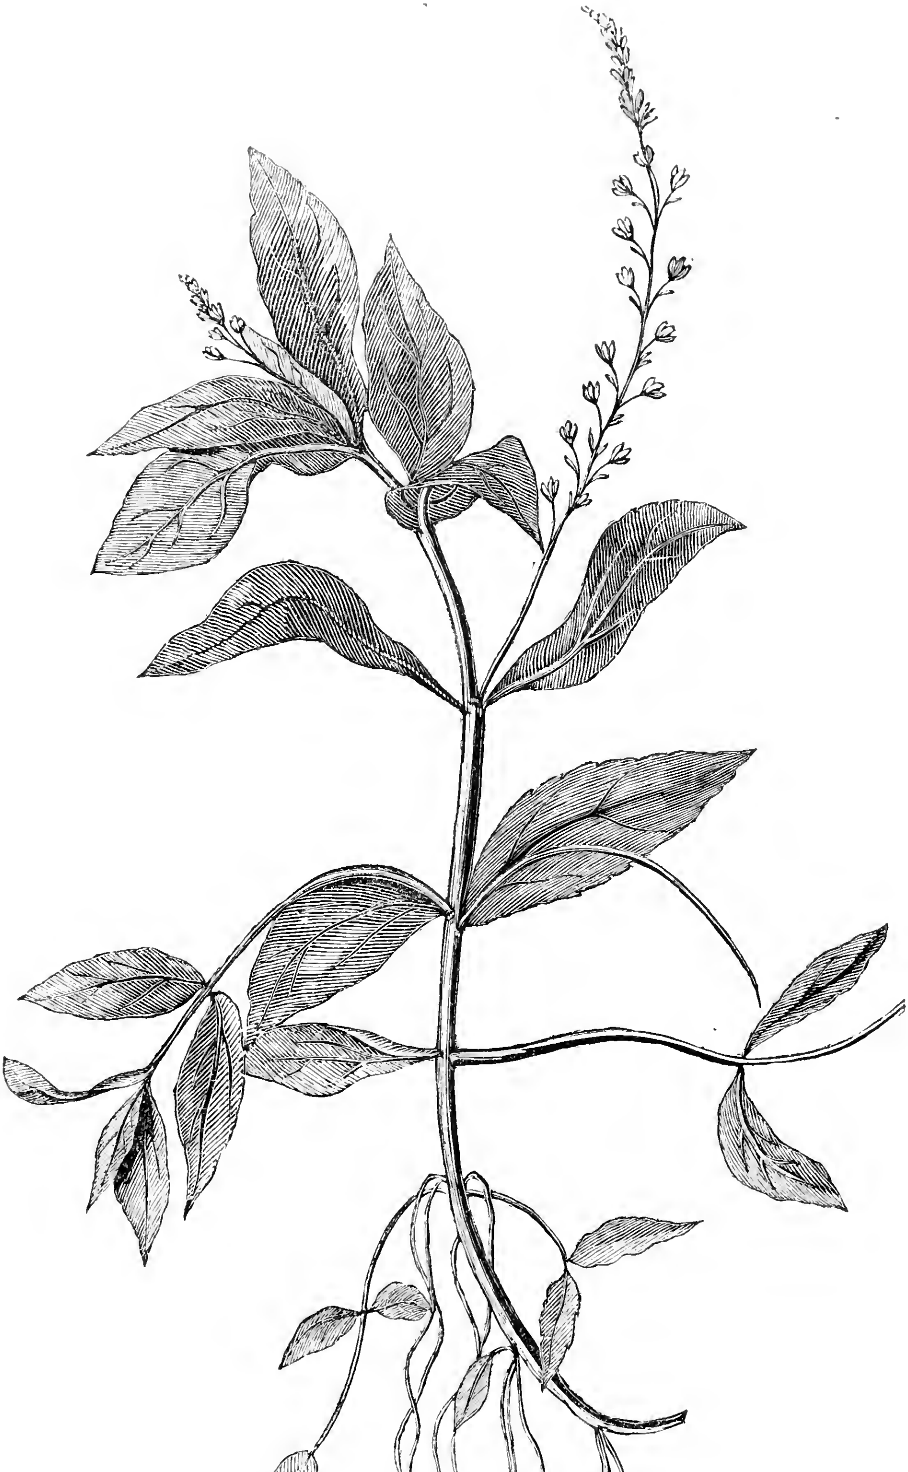
It is certainly a question of some importance, whether the worn-out lands of Delaware, Maryland, and other parts of our country cannot be improved at less expense than to clear off the almost impenetrable forests of the west. When we consider the time it necessarily occupies to clear and make ready for the plough a hundred acres of heavy timbered land, the expense of labor, where labor is not easily obtained, the distance from market, the privations and hardships inseparably connected with new settlements; it seems at least worthy of an experiment to ascertain the fact. A SUBSCRIBER.

Wilmington, Del. 5th mo. 18, 1837.

THE MARL INDICATOR.

It has been long and generally believed among the marling farmers of King William county, and the adjoining country, that the growth of a certain plant, in running water, indicates, with absolute certainty, the presence of marl, or beds of fossil shells, some where higher up the stream. The great value of any such indication, to those who are searching for marl, is obvious. We were informed of the peculiar rule of location of this plant several years ago, by our friend and correspondent, Dr. William B. Westmore, then a resident of King William; and, at that time, requested such particular information as would enable us to identify the plant, and, by publishing the description, to furnish all the readers of the Farmers' Register the means to avail of its use, in showing the before hidden presence of marl on their lands, or in their neighborhood. Dr. Westmore caused a correct colored drawing to be made of the plant, by a good artist who happened to be at his house; and from the drawing we have had engraved the representation which accompanies this article; and which, with our own description, may enable persons without botanical knowledge to identify the plant. But to those who possess any thing of that knowledge, (to which we have no pretension,) a much surer means of identification is offered in the following report of the botanical character of the plant, which was furnished at our request by a correspondent, who is much better informed on the subject, and to whom the growing plant was exhibited. His report was as follows:

"I carefully examined the plant you pointed out to me, when here, as indicating the presence of marl in the earth, or as growing only in streams supplied with calcareous matter. Though the flowers are very small, the botanical character is obvions, and easily determined. The plant belongs to the second class and first order of the artificial system, (*diandria monogynia,*) and to the genus *Veronica* of that order. Loudon describes 84 species of this genus, only one of which (*Veronica Virginica*, with a variety, *Incarnata,*) is American. This plant does not agree with any of the numerous species described by Loudon, and I very much doubt whether it is described by any bota-



The Marl Indicator.

nist. I would, therefore, be inclined to consider it a new and important species. Its botanical description is—root fibrous, stem smooth, leaves opposite amplexicaul, lanceolate, slightly serrate, flowers racemose, axillary, calix four-toothed, corolla light blue, entire base; lip four-parted, capsule two-celled. Should this be (as I think there is every probability) an entirely new species of *Veroncia*, would you permit me the liberty of suggesting a specific name—*Veronica Ruffinia?* If its presence is a sure indication of marl, it is a highly important plant, and your name is almost identified with marl."

We beg leave to decline the unmerited honor above proposed, as we have no claim to the discovery—and but only that of having appreciated the facts, as soon as they were heard of, and now of making them public. We should think the name of *Westmorea* more appropriate; but our friend Westmore also waives all claims to the discovery, and says, that he does not know who first noticed the connexion of the plant with marl. And if, contrary to the present supposition, the plant should in fact have been long on the catalogues of botanists, it will not the less deserve to be considered, for its peculiar quality now just brought to light, as a new and important agricultural discovery. We prefer for its name, the descriptive one of the "Marl Indicator."

But we have further evidence of this being in truth a new species, in the opinion of our friend and correspondent, Gideon B. Smith of Baltimore, to whom we sent the drawing to have it engraved, accompanied by a statement of the peculiar value of the plant, and a copy of the foregoing botanical description. His answer says—

"I cannot determine the botanical character of the plant from the drawing, but it certainly appears to be a Veronica. The description of the plant and the drawing agree perfectly, so far as I can follow the latter—the characters of the corolla, calyx and capsule not being distinct in the drawing [owing to their small size.] The plant is new to me; it is not described by Loudon, nor, so far as I can find, by Elliott, nor any other botanist to whose works I have access.

"It will be a curious and valuable discovery for the agricultural interest, should it prove to be in fact an indication of the presence of calcareous matter; and I shall certainly bear it in mind in all my botanical rambles."

We readily found this plant growing in several of the rivulets flowing through different beds of fossil shells, or marl, on our farm. For the fact that it is to be found in none other than such streams, we have as yet to rely on the information of others; and on the certainty of its absence as well as its presence agreeing with the absence and presence of marl, obviously depends the value of the "indicator."

The plant is an evergreen; it grows only in shallow water. The stalk is seldom more than a foot high; though we found some 2½ feet. It is so succulent and tender, that it droops and withers very quickly after being pulled up, and left dry; but when immediately placed with the roots in a bottle of water, it continued to live, and to throw out successive flowers for several weeks. It was in flower in May, and had not ceased to flower in the beginning of September. The flowers are very small, of a pale blue, or nearly of a lilac color, and appear in small clusters, or strings.

We have taken much trouble and incurred some expense, to enable our readers to identify this plant. It is hoped that many will search for it, and test its alleged peculiarity of location; and if observation should serve to disprove that peculiar character, it is further hoped that such observation and facts will be communicated for publication. To correct erroneous opinions, and mistaken facts, is as useful and as necessary to agricultural knowledge and improvement, as to announce new and undoubtedly true opinions and facts.

As no calcareous earth exists in the tide-water region of the southern states, except the fossil shell deposite, or marl as commonly termed, of course the growth of this plant, when found any where in that region, will always indicate that form of calcareous earth only. But if it grows among the mountains, and in more northern as well as more elevated lands, it will probably be found in all limestone streams.

AGRICULTURE OF UPPER FAUQUIER.

To the Editor of the Farmers' Register.

In fulfilment of a promise which I made you at the Fauquier Springs, I proceed, at as early a moment as it is possible to compose my faculties, after the stir and bustle of that deservedly popular watering-place, to give you some account of our agricultural operations in upper Fauquier. I could well have wished that this task had devolved on abler hands, and it is only in consideration of the honor done me by your request, that I now make the effort.

Before entering on the subject immediately in hand, I beg leave to be indulged in a few preliminary observations. Farmers scarcely ever write well, in consequence, perhaps, of the "difference between the diameter of a pen and a plough-handle." Be this, however, as it may, I consider farming, of all subjects in the world, the most difficult, in every thing which relates to it. To plough, to sow, to reap, garner and to gather; to sell, to buy, to use and not to abuse, are all apparently the most simple things imaginable; but, in practice, we know that each and every one of these operations are attended with difficulties which no novice can appreciate, and to overcome which, many men have utterly failed, even after growing gray in the service. And to render to the public a graphic description in detail of even a part of the mysteries of this wonderful trade, is found to be no less irksome, than to lead the operatives in the field.

On this subject, at least, the world has certainly had the advantage of a great deal of practice, without treasuring up, however, the benefits derived from much useful experience. The truth is, that from the diversity of soil, climate and the seasons, the operations of an agriculturist cannot generally be reduced to any fixed rules, and hence the knowledge of the art, is not, to any available extent, transmissible. The writings of almost all the agricultural associations and societies that ever existed, are now laid upon the shelf as useless lumber. Every man has to be the founder of his own system, and even *that* it is often necessary to change from year to year. In proportion to numbers, there are few good farmers in any country: and even among the best of them, success rarely results in the accumulation of large fortunes. A competency—a very moderate degree of independence, is all which the most of us aspire to, and even that, many fail ever to get. To make a good farmer, it requires a combination of prerequisites rarely to be met with in the same individual: he must possess the patience of Job, the wisdom of Solomon, the eyes of Argus, and the equanimity of a saint.

It is said, that between man and the earth there is a natural sympathy: the earth, "from which in sorrow he came, and to which in sorrow he must return." Every man, at some period or another of his life, aspires to the honor of becoming a cultivator of the soil; to plant a tree, the fruit of which he may never taste; to build a cabin or a villa; to enjoy a little of the "*otium cum dignitate*," supposed to be incident to the profession; to rear up an inheritor of his name and fortune, and to deck the bosom of that earth, in which he knows, at no distant day, he will find a grave.

Adam, our great progenitor, was a farmer, or, at least, it was intended that he should be one, even before his fall; for, when placed in Paradise, he was directed "to keep it and to dress it:" but he lacked experience, and managed his affairs very badly, for he lost his inheritance, "which brought death into the world, and all our wo," before he probably had pitched his first crop. Most of the patriarchs were graziers; and that rich old gentleman, Abraham, was one who did no discredit to the profession. In his entertainment of the three angels, who unexpectedly paid him a visit, his running "to fetch a calf, both tender and good," and his directions to his dutiful wife, Sarah, to cook the cakes on the hearth, we have a most beautiful picture of primeval hospitality and simplicity. The fare was plain and abundant; but how different the style from that of a wealthy herdsman of the present day!

To feed well, is one of those indispensable requisites, that cannot be too often inculcated. A farmer should feed every thing well, and last, though not least, he should feed himself well. His house should be the seat of social comfort, of hospitality and affluence. I hold no communion with your lank-visaged Shylock: he, who exacts "his pound of flesh," eats little himself, and drinks—he drinks water; and there is, after all, no real sociability without the occasional use of the "wine-cup." We are pleased with the caricature of a "turtle-fed alderman;" we are delighted with the admirably drawn character of Falstaff, the personification of good living, the very prince of good eaters and deep drinkers; we can pardon, at least, the vice of a hospitable "landlord, who never suffers a guest to leave his table, either sorrowful or sober."

There is no truth in the adage, "that there is no place like home, though never so homely;" many a poor fellow, with at least an ordinary share of the milk of human kindness in his soul, roams through the wide deserts of this cheerless world, until brought up at last by starvation and death, for no other reason, but that he has no home, or none at least with such endearments as to make life desirable—no blazing hearth—no smoking board—no prattling children—and worse than all, "no eye there, to look brighter for his coming."

A farmer should retire early to bed, and require no such monitor as Dr. Franklin, who once informed the citizens of Paris of the astonishing fact, "that at 5 o'clock the sun was up, and that it was quite light;" but with his eyes wide open, at early dawn, let him "first see that all is right, and then go ahead," without the necessity, however, of wending his way, either to "the Devil or to Texas."

I cannot speak for others, but I know that farmers like a warm fire—a cheerful candle—a comfortable bed; they like to dream of pleasant times that are past, and of a joyous prospect to come—"of wife, children and friends"—of fat beeves, of full hog-pens, of heavy stack-yards, with real old-fashioned Bonaparte pieces booming in the distance.

After this long preamble, it is time to come to the real object of this letter, and, to do it to your satisfaction, I shall try and "begin at the beginning." Fauquier county is one of the largest and most populous in the state, east of the Blue Ridge Mountains. It is composed of two large oblongs, joined together by a narrow neck of land, just at Warrenton, a little above the White Sulphur Springs. The land in the lower section is not good, the upper and larger section I shall now attempt to describe. From Warrenton to Salem, there is a good deal of poor land, but above Salem, in the direction of Farrowsville, Upperville and Middleburg, the land is generally excellent, some very tolerable, and only a small portion ordinary. The country generally is broken, rough, rugged, hilly, mountainous, stony and rocky. It is as healthy as Montpelier, and as finely watered as any portion of the habitable globe. It is a fine farming country, though not picturesque; it is occasionally romantic, but not generally pretty.

A traveller, in passing along any of the public highways, would not be impressed with the beauty of the scenery, the good appearance of the houses, or the excellence of the cultivation. Wood is in many places scarce; but still Volney would pronounce it, in comparison with France, "a great forest;" so great is the predominating effect of wood land over cleared and open fields. The general surface, as presented to the eye, is not only rough and broken, but intersected by numberless branches and little swamps, left for the most part intentionally uncleared. These, though unsightly, answer the double purpose of protecting the springs and streams of water, and of affording shelter for cattle.

The soil, in its natural state, is generally good, but not first rate, as compared with that fine region of country in Maryland, between Hagerstown and Frederick, or with some localities beyond the mountains. As far as I have been able to ascertain the fact, it is composed of seven-tenths of clay, two-tenths of sand, and the remaining tenth of vegetable matter, a little iron, and a small quantity of calcareous matter, with a substratum of stiff red clay. There is certainly too little *humus*, and probably too much clay for a perfectly good soil, or for it to be ploughed easily.

Large crops of wheat are grown in upper Fauquier, and we consider it an excellent soil for that grain, and inferior only to good limestone land; for corn and oats, it is better than any limestone; for rye, it is unsuitable; but for grass, when aided by plaster, it is unsurpassed by any land in America.

This fact points to a source of profit in grazing, to which we have not been slow in resorting—as many cattle being fattened in this section of country as in any other area of equal extent in the Union.

We sow a great quantity of clover and other grass seeds, and use plaster liberally on every plant which we attempt to raise, and this sometimes acts with an energy truly astonishing. We work well—we plough well—we cultivate well. But what constitutes good cultivation? not certainly the deepest ploughing, as supposed by some, or the most frequent ploughing and harrowing, as advocated by Tull. Without pretending to any skill in definitions, I should say, that is the best cultivation, either for wheat or corn which most completely destroys, or holds in obeyance, all spontaneous vegetation, so as to give the crop a monopoly of the soil. The *most perfect* cultivation for wheat would be, to plough in the spring, to cross-plough after harvest, harrow—sow the seed, shovel in, and then harrow again. But this is not the Fauquier method of doing the business; neither is it the best way: a single good ploughing, by which I mean that the surface should be completely turned under, with the wheat sowed on the rough surface, if there be not too many clods, and then two good harrowings are all-sufficient.

The reason for this is very obvious, which it may be as well perhaps to state. When land is first ploughed, the vegetable matter turned down undergoes a decomposition more or less violent, agreeably to the presence of heat and moisture. When the grain is sowed, immediately after the ploughing, it receives the gas as it is generated, like a plant in a hot-bed. But if the land be ploughed a great while before seed time, there is a loss of all the volatile part of the manure, which failed to combine with the soil. And the same reasoning is applicable with still stronger force to the corn crop. Fall ploughing for corn is now very generally abandoned.

In farming, generally, we use much less manual labour than our brethren in lower Virginia; we depend more upon the cheaper service of the horse and the ox. The plough has in a great degree superseded the use of the hoe. It may be admitted, however, that we have too little manual labour. And this proceeds from necessity. The "cotton fever," which raged so intensely a few years since, to the south, not only carried off some of our most active and enterprising people, but deprived us to a very injurious extent of our negroes. I shall not stop to bandy words with those who may deem this a blessing; it is sufficient for my purpose now, barely to state that we, whose interest is most affected, view it in a very different light.

In a country so rough as this is, where there are so many stones, both in the ground and out of the ground, and so many fences yet to be made out of them, a very strong force might be used to advantage, independently of that which is necessary for mere cultivation. The farms, also, are generally rather large, with a strong, but very natural tendency to accumulation in the hands of the few, to the exclusion of the many. "The rich are becoming richer," but the poor, not being willing "to become poorer," are going where they can "get richer" too—they are going to "the great West."

A great deal is generally supposed to depend on a judicious rotation of crops; but the most important thing at last is not to cultivate the land too frequently in any crop. Exposure to the influence of the atmosphere is of much more injury to a soil, than the loss of that portion of vegetable matter, which constitutes a part, and only a small part, of the food of plants. A quick rotation is generally adopted, from the fear of the effects of blue grass; but this, like every other vegetable, or animated production of the earth, has its period of youth, maturity, and decay, and a sod of five years' standing is more easily subdued by the plough, than one of three, besides possessing the advantage of being able to bring from a fourth to a third more grain. The grazing of so many cattle enables the farmers of this neighborhood to keep a large portion of their arable land constantly and profitably in grass. This accounts for the rapid improvement of the country, and the prosperity of the people.

The proprietors of upper Fauquier are generally the builders of their own fortunes. If we have few very rich men, we have, on the other hand, not many that are poor: the great mass is composed of "middle interest men," the bone and sinew of every country. Some of the refinements and luxuries of the world may yet be wanting, but we live abundantly, and, I hope, hospitably. To the ornamental part of our profession but little attention has been paid; our farms have nothing of that garden-like appearance, with which Hazlitt was so delighted on a long journey through Lombardy; neither are our dwellings embowered in trees, or embellished with tasteful enclosures, and the beautiful shrubbery and flowers of the sweet little cottages of England. But, the Bible says, "there is a time for all things." We now "go for the main chance," and hope to leave to our children, the means, and there will be plenty of room, for the exercise of all their taste in ornamental agriculture.

I remain,

Your obedient servant,

R. B. Buckner.

St. Bernard, 20th September, 1838.

For the Farmers' Register.

THE THEORY OF MANURING WITH LEAVES, SUPPORTED BY A FEW EXPERIMENTS.

There are no truths in the science of agriculture, not immediately obvious to the senses, more susceptible of proof, than that much the greater part, if not the entire substance, of every vegetable is constituted of precisely the same elements, or materials, merely differing in their proportions; and, consequently, that every vegetable substance, when suitably reduced or decomposed, is food for growing plants of other kinds. Hence it must necessarily follow that every kind of vegetable matter must be an alimentary manure; and if it does not act as such, or to much extent, that it is not because the substance does not possess the raw material of which to make manure, but on account of some inconvenience attending its form, or defect in the mode of application.

Upon such grounds, theory would pronounce, even if practice had not at all confirmed it, that the leaves of trees furnish a material for alimentary manure; and, in as much as the quantity in the reach of most farmers in Virginia, is super-abundant, that this resource for fertilization, if properly used, would be of incalculable value, on all lands so constituted as to be profitably enriched by any other vegetable manures. On soils wanting this proper constitution, profit is not to be expected, either from leaves, or from far richer vegetable manures.

But, putting theory aside, (as its authority is deemed of but small value by most cultivators,) there are enough examples, in the regular practice, and the results, of many successful farmers, to place beyond question the advantage and profit of using leaves as manure. Many striking facts of extensive and successful use of leaves as manure have been reported in the Farmers' Register, in the practices of sundry good farmers, and profitable enrichers of land.

Still, however, many other farmers have commenced, and made, for a while, energetic efforts to collect and apply leaf-manure, and have encountered so much trouble for so little of appreciable or manifest improvement, that their efforts soon slackened, or totally ceased, because they were supposed not to be compensated. Such was the impression and the course of the writer of these remarks, after a very large use of leaves for one year. But being now satisfied that the failure was owing to his own improper practice, and not to the want of value in the material used, he will state what he believes to have been his and the general errors in the mode of application; and the few facts since ascertained, as well as the reasons, which recommend a different and cheaper mode.

Though nearly the whole of every vegetable substance is a material for manure, and capable of becoming food for growing plants, it is far from being the case that all, of any one substance, is ready so to act at any one time. And it may well be with some substances, which strongly resist rotting and decomposition, that the portion which is fit to feed plants is so small, at any one time, and the proportion of the unfit (and for the time, therefore, hurtful,) so large, that no profit, or perhaps benefit, would be derived from the most abundant applications. No part of vegetable matter is ready to act as manure, unless it is at the time soluble in water; as it is only when fluid, and dissolved, that it can be taken up by the very small absorbing mouths of the roots of plants. (See Davy's Agricultural Chemistry, Lect. I, and VI) Therefore the deduction is clear, that if of 100 pounds of leaf-litter, applied as manure, 5 pounds only are soluble, the other 95 pounds are, for the time, useless; and, if buried in or mixed with the soil, may even be injurious to the crop. Saw-dust is a vegetable substance, containing still less soluble matter, and is very slowly decomposable; and though its entire substance also is capable of becoming food for plants, and of course manure for the soil, yet it has not been found worth using, in any common mode of applying manures. Tanner's spent bark, also, for immediate or speedy action, is worthless as manure, and would do more harm than good to the first crop. Vegetable substances, of a more decomposable nature than these, when under a low temperature, continue undecomposed, and of course insoluble, for ages; and, in that state, are a cause of sterility, instead of being manure to the covered soil. Such are the peat lands of Scotland, and other cold and moist countries. In such regions, there is but little of naturally poor land which, if let alone, will not, in the course of time, be covered with some inches' thickness of peat, or pure and solid vegetable matter, formed from the annual dying and deposite of the plants growing thereon; and in the most favorable situations, this covering of inert and almost barren vegetable matter, increases to many feet in thickness. Yet all these vegetable substances are still composed of materials fit to be converted to food for plants. This conversion of peat has indeed been made, in practice; and not only in scientific experiments, but economically, and profitably, in practical agricultural improvements. The means used were to make the peat into compost, with both alkaline and highly putrescent animal manuring substances, so as to induce fermentation and decomposition in the before inert and dead peaty matter. Such would be the case with any other of the least decomposable and soluble of other vegetable matters. But though theoretically true, it may well happen that the returns from some such substances would not compensate the labor and other cost of converting them to active manures. Such, however, is not the case with leaves; which, in this climate, are not too slow or difficult to decompose, even without any admixture of either alkaline or animal matters, and which are far richer in nutriment than the more intractable and insoluble substances named above for illustration.

But while maintaining the value of leaves to be important, on account of their great quantity, and usual cheapness, it is not pretended that they are to compare in richness, bulk for bulk, with straw. Upon the grounds stated above, it is presumed that their whole substance is a fit material for food for plants, and therefore may be entirely converted to manure. But still it will be a poor manure, in comparison to most others in common use, and of established value. Articles of food for plants, like those of food for animals, may be altogether nourishing; but yet nourishing in very different degrees. Thus, though meat, bread, and potatoes, are all excellent and nourishing food for man, still the nourishment received from an ounce of meat might be as much as from six ounces of bread, or from twenty of potatoes. And still the potatoes may be the cheaper and more fattening and profitable food, if, to a starving people, forty times as much in quantity can be furnished as of meat, at equal cost. This is the mode in which the value of leaves should be estimated, in comparison with farm-yard and stable manures. And the farmers who commence their use will be disappointed in the results, if they make their cost (in the labor of preparation and application,) equal to that of farm-yard manure, or expect equal effects, from equal quantities.

In applying leaves, and in large quantities, as manure, the first object of the farmer should be to make the mode of application as cheap as possible; and the next, to prevent any of its effects being actually injurious. Neither of these objects are usually attained; and hence the many disappointments in the early practice, and the general relaxing, if not entire cessation of effort in this direction. Such was the result of my own early and very extensive use of leaves; although I did not commit both these usual errors, but only the one of making the application too laborious and costly to leave any *certain* profit. My erroneous and unprofitable applications were very large; those made on more correct views, and giving satisfactory results, are more recent, and comparatively but small.

In the beginning of the winter of 1832-33, I first commenced the use of leaf-litter on a large scale, and with a view of making it a regular part of the operations of the farm. My land had then been all made calcareous, (by shell-marl,) and the soil, therefore, was then fitted, though incapable of it before, to be profitably enriched by the use of putrescent manures; and the efforts to accumulate them, and the care in saving and applying them, (which had been but small while the marling was going on,) had been extended since a year or two, much beyond my previous habits, or the general careless habits of our country, though still they were very far behind what good and improving farming would require. The offal of the grain crops were all used as food or litter for the farm-teams and a small stock of cattle, and were applied, well or ill, to the crops. My difficulties and doubts as to the best mode of securing the value of manure, and sundry experiments on the heaping and fermentation, were presented in several pieces which were published anonymously in the Farmers' Register, at page 136, vol. I, and pages 497 and 669, of vol. II. It is enough here to say, that my general mode was to have all the vegetable matters trodden by the stock in the stable and barn-yard; and the only question in applying was, whether fermented or not, or to what extent and in what manner to carry the fermentation of the manure. This was the state of things, when, by heaping the leaves in the woods, my bulk of litter was nearly doubled. For so small a stock of mules and cattle as mine, the offal of the crops had before furnished more than an abundance of litter, for profitable admixture with the animal matter. And by adding as much more, of a still poorer material, there was probably not much value gained merely by the mixture, (or more than the leaves might have had in a separate and cheaper application,) and the whole labor of hauling, in and out, heaping, loading, spreading, and ploughing in, was doubled. The portion of benefit due to the leaves alone could not be separately estimated, or fairly appreciated; and, with all the desire felt to find a favorable result, the whole benefit from the manure was not enough to admit of allowing much profit to have been derived from the leaves. Without being able to make any fair estimate of the whole benefit derived from the winter's manure, and not even to approach an estimate of the leaf portion of it, the result, as to the latter, was altogether discouraging. There was no evidence that the application had paid for the labor.

Another mode of application had also been tried on from 10 to 20 acres. It was evident that the passing all the leaves through the cattle-pens would require more labor in the after-operations than the farm could spare. Therefore, the leaves, as raked up in the woods, in mid-winter, were hauled directly on the land designed for corn, and dropped as thick as they could be ploughed in tolerably well, after being spread, by ploughs running 6 or 7 inches deep. The quantity to the acre is not remembered; nor can I say what the *supposition* was of the benefit derived to the next or any succeeding crop, as I did not reside on the farm; and not long after, my personal attention was almost entirely withdrawn. But this is certain, that there was not enough benefit to promise reward for that mode of applying leaves.

These results were discouraging, and to most persons would have been sufficient proof that leaves were not worth using. But I had been satisfied, from the beginning, that there were great objections to all the methods tried, and that no fair trial could be made, or full value known, until these defects of practice were avoided. A small experiment of what was deemed a better method, helped to strengthen my opinion. Still, the wretched superintendence and consequent bad management of my farm for some years, and latterly the want of spare time, and other labor, have prevented the reducing my plans to practice until last winter, and then not to half the extent that is hoped to be reached in the approaching winter, and henceforward.

The defects, which should be avoided, will first be stated; and to know these defects, it is necessary to recur to the chemical constitution of leaves, in different conditions, and to the established principles of the nutrition of plants. It has already been stated, that nothing can act immediately as food for plants, except it be then soluble in water. Therefore, whether it be of the richest rotten farm-yard manure, or of recently-fallen and unrotted leaves, the only parts that are ready to serve as food for plants is so much of each as can be dissolved in water by being soaked in a sufficient quantity, and for a few hours, or days. The soluble proportion of the rich and rotten manure would be very large; and of unrotted leaves, very small. But small as may be the latter, it is rendered less, if not for the greater part removed and lost, by every heavy and thoroughly soaking rain that falls, and which must dissolve and carry off, or into the earth below, most of the extractive or soluble parts of the leaves so treated. But the wetting promotes decomposition, and consequently, the conversion of insoluble to soluble matter; and whenever another heavy rain falls, there may be again formed as much or more soluble matter as before, to be again dissolved, and again lost. Thus, though it may take five or six years for the leaves of one year's deposite on poor wood-land, to rot entirely, and though, in that time, all the parts may have been successively soluble, and ready to feed plants, still, at any one period the quantity then ready to act was very small, and the value of the whole was made less and less by every successive rain. Leaves which have been two or three years lying on the ground where they fell, and are rotten and much reduced, appear richer, and more like manure, and perhaps may be more fertilizing at the present, than newer leaves. But still the former have already lost, by decomposition, and washing by the rains, half their bulk, and more than half their strength.

According then, to this reasoning, the first error which is generally made in collecting leaves, is to prefer the old to the new, and to be regardless of the lapse of time, and exposure to rains, both of the new and the old leaves.

Some farmers, who regularly collect leaves to litter their stock, and make manure, and who have more wood-land than they need to rake every year, divide it into several portions, and rake each portion in succession; so as to get as large a proportion as possible of the oldest and most rotten leaves. Their course should be precisely different; and if new leaves enough could be secured, and with equal ease, it would be better to let alone those of previous years, which have been already robbed of the greater part of their fertilizing ingredients. It is not meant that, when raking a piece of wood-land, the lower and older leaves should be left. That would cause much more trouble in the separation, than gain in the difference of quality. But, after having once removed the whole cover of the leaves, it will be more profitable to rake the same land every succeeding year, and thus obtain recent leaves only, rather than to go elsewhere for a thicker and more rotten layer, formed principally of leaves which have been soaked in every rain that has fallen in two or three years. This opinion, however, is deduced entirely from reasoning, and has not been tested by experiment.

If, however, in the absence of proper experiments, any one doubts the great waste of the soluble matter of leaves, let him take some that have recently fallen, and are quite dry, and soak them for 12 hours in a vessel of water; and the color given to the water, alone, will show that there is much loss, in that short time. Every heavy, or long-continued rain, has fully as much effect on all the dead leaves then exposed. The much greater part of this matter extracted by infusion, sinks immediately into the earth below, and is not seen, and, therefore, cannot be appreciated. But, on poor soils, (or all very deficient in calcareous matter,) after heavy and continued rains, the puddles and streams of water are all more or less deeply tinged with the brown-colored extract from the leaves; and the permanent streams, mill-ponds, and even lakes and rivers formed of water flowing from such lands, are always so colored. Such examples are numerous in lower Virginia, wherever the lands are naturally poor, and there is no calcareous matter in the soil over which the water passes. No such coloring matter remains in the water on calcareous strata, or on good natural soils, the goodness of which is evidence of lime being contained. In such cases, the vegetable extract is seized on by, and combines with, the lime, or the soil containing lime, and is saved for fertilizing use, if the soil is in a state fit to produce any valuable crop. But, if the land on which the colored water flows, or stands (in ponds) or sinks into, has not the natural constitution to enable it to attract, and chemically combine with, vegetable extractive matters, or vegetable manures, then this kind of food for plants will not be retained, nor be profitable to be applied thereto, any more than other putrescent manures on the most ungrateful soils. The propriety and profit of applying leaves, as of every other putrescent manure, of course depends on the fitness of the soil to receive such benefit. This is not the place to set forth the causes of such different qualities of soils, (and which has been done elsewhere,) and in all the remarks on the benefit of applying leaves as manure, it is understood to be on soils which would return good profit for the use of other vegetable manures.*

* See Essay on Calcareous Manures, second edition, chap. 2, 3, and 8.

If the opinions expressed above are correct, the proper practice in collecting leaves, and one totally different from the common mode, may be readily inferred. Those who collect leaves for manure, seldom rake up and heap any soon after they have fallen, and before they have been soaked by many successive rains. The raking is most generally done at leisure times, in the latter part of winter and in spring, and is sometimes continued through summer and autumn, to nearly a year after the newest of the leaves have been lying on the earth, soaked by rains, and wasting continually. If this litter, so used, is found highly advantageous by improving and judicious farmers, (of which there can be no doubt,) it is even more certain that their profits from it would be much greater, if the collection and application were made without permitting such waste previously to take place.

The raking up and heaping of the leaves, in the woods, ought to be effected as soon as possible after nearly all have fallen in the early part of winter. The work is done much the easier if the leaves are wet; and therefore a slight or slow rain, just before, is desirable. Even a single heavy rain, if not continuing very long, may assist the collecting and removal of the leaves, more than it will diminish their soluble and enriching parts. Besides, by being put up wet, decomposition will proceed in the heaps; but if heaped dry, and especially if principally of oak (or any other than pine) leaves, the upper part of each heap, forms a thatch almost impervious to rain, and the interior of the heap may remain dry and unchanged for a year. Every effort should be made to have the leaves raked up, and put into good stout heaps, as early as possible after the proper time. But after being heaped, and secured from the wind by a few hoefuls of earth, they will lose little or nothing by waiting months, or perhaps even a year, for a convenient time to be carted away and spread on the fields.

The poorest lands, when not annually raked, yield the greatest bulk of leaves; because the acidity of such soil retards the rotting so much that the leaves of five or six years may be on the surface at one time. On calcareous and rich soils, there being not only no acid, but also a strong chemical action or attraction between the soil and any vegetable matter in contact, the leaves soon disappear, if not raked up and heaped. On a small piece of wood-land, of soil both calcareous and very rich, I had the leaves raked into heaps during winter; and when hauled away the next autumn, the heaps were well rotted, and as "short" and as black as old fermented and dry farm-yard manure. Heaps made about the same time on the poor huckleberry ridge forest lands, in the same space of time were but little altered.

The greater proportion of pine there is in the forest growth, the more valuable the cover of leaves; and of course the old worn-out lands, bearing a second growth of unmixed pine, are the best to furnish this manure. There is more of substance and weight in the same bulk; the pine leaves are more easily handled in every process; and from their narrow and compact form, they oppose no impediment to the young spires of any crop on which they may be laid, and for the same reason they are not liable to be carried off by the winds. Farmers more experienced than myself in their use, and whose opinions are therefore of more worth, also believe that pine leaves are richer, than those of the other usual forest growth, whether comparing weight of litter, or the spaces of ground furnishing the different kinds of leaves.

The next greatest error in leaf-manuring upon a large scale, is passing more of the leaves through the farm-yard, or stable, than are needed for plentiful litter to the animals, and as a vegetable material to absorb and mix with the richer animal matters. When so poor and so slowly putrescent a substance as new or dry leaves are used as litter, and in very great quantities compared to the richer ingredients of the whole mass, the manure will not be fit to use profitably for corn, or other spring crops, without its being heaped, and more or less fermented and reduced. This labor, and this source of loss, would be a serious matter, besides the having double handling and hauling of the leaves, before applying them to the land.

If, to avoid the heavy cost of twice loading and twice carting of many hundreds of loads of leaves, they are taken at once to the field, and spread and ploughed under, unmixed and unrotted, then another great loss will be sustained, in the trouble of ploughing under, and afterwards among, such a cover of unrotted litter, and the early unfitness of the leaves to nourish or help the growing crop, even if it does it no positive harm (as would seem very likely) in a dry summer. If left to choose between these several modes of application, it would be difficult to decide in favor of either; and it may well be doubted whether either, on a large scale, and requiring much of the regular labor of a farm, would be of much profit. But judging from reason, more than from my yet but small experience, it still seems manifest that all farmers who can easily obtain leaves, in great quantity, and will put them on soils fit to receive improvement, and on a different method from any of those above described, may thereby improve their land and their profits, greatly and cheaply. My proposed plan is the following:

1st. To make and heap as much leaf-litter, in the woods, as the demand for other farm labors may permit, early in the winter; and the balance afterwards, as soon as convenient, and at leisure times. The leaves to be heaped when moist, in preference, and the heaps to be kept safe from wind, by having thrown on them a few sods of huckleberry roots, or a few hoefuls of earth.

2d. To use as litter for stock no more than is required; and to cart, as convenient, up to the time of next harvest, the leaves on the land, to be immediately spread, as top-dressing. The principal application, through winter, especially of the litter composed wholly or mostly of pine leaves, to be on the growing wheat; and in the spring and early part of summer, on young clover sown the season previous. When not convenient on either, the leaves might be spread on any land in natural grass, or weeds, and not intended to be ploughed until the next year, and not to be grazed.

It will be obvious at once, that whether much or little improvement is found from this mode of application, that it will be at but little cost of labor. There is no double loading and carting—no labor or loss in heaping and fermenting—no ploughing under or among the leaves while unrotted—and no possible injury to a growing crop. And if it is beneficial to top-dress young wheat with other vegetable manures, and young clover and other grass with dry and unrotted straw, as well as farm-yard manure, (both of which I highly approve, and have practised as largely as convenient for several years,) then there can be no ground to question the soundness of my conclusion, that whatever value there may be contained in the leaves will be given in this manner most completely, as well as by far the most cheaply.

My earliest trial of top-dressing young wheat with fresh and dry leaves was in the beginning of the winter of '33–4, and was made soon after the wheat had come up. If it could be done at so busy a time, it would be much better before the coming up of the wheat; as it would be less troublesome, and less liable to injure plants by the carting. Pine leaves were used, as others would have been blown off by the dry March winds; and they were necessarily put thinly, to avoid smothering the wheat. The quantity to the acre is not known more accurately. As was expected, the slight cover of leaves served evidently to protect the young plants from the severity of the cold weather in winter; and from this mere mechanical effect, (which is independent of and distinct from any alimentary or enriching matter furnished by the leaves,) there was a very perceptible, though but slight benefit exhibited by the top-dressed wheat, before any could have been supposed to be produced by the leaves as manure. A slight superiority continued plainly to be seen until the growth was well advanced, which was as late as it was observed.

It is admitted that this improvement of the crop was but small; but the cost of the dressing was also very small; and the mechanical part of the benefit, (which was probably all that was derived by that first crop,) must be certain in every winter, and might sometimes save a crop that would otherwise be killed by the severity of the cold. If clover is sown on the wheat, that also would have the same mechanical protection, both from late cold spells, and from the heat of the following summer. My later practice of this year, as will be stated below, has shown this particular and very important benefit in a striking manner.

The slower fertilizing action of unrotted leaves applied as top-dressing to clover, or other crops, will be less evident or perceptible than the mechanical. Upon my own recent and only judicious applications, there has not yet been enough lapse of time for the best effects to show. I do not pretend, therefore, to estimate what may be the full benefit derived from a certain amount of leaves laid upon a certain space of ground, nor to affirm whether much, or but little increase of fertility will be thereby produced. But having full confidence in the propriety of using dry straw and other more putrescent manure as top-dressing, in preference to ploughing under, and on young clover, in preference to grain crops, I have equal confidence in that mode of applying leaves, to profit by their full value, whatever that value may be.

It was not until last winter that the state of my farm, in other respects, made it convenient for me to resume collecting and applying leaves, to any considerable extent, and entirely upon the surface—the former modes being deemed of no certain advantage, above the value of the labor employed. The want of sufficient spare team-labor still caused the quantity applied to be much less than will be applied annually hereafter, if there is no disappointment found in the effects produced. The general results of the last applications have, so far, been highly gratifying. Particular effects, which were more carefully observed and noted, will be stated in the report of my manager below. The early benefit which he reports on the wheat, and striking later benefit to clover and weeds, the *apparent* destruction of wire-grass, covered by the top-dressing of leaves, laid on as brought from the woods, I observed myself, at different times of hasty and widely separated visits to the farm. But as there was much that is more of general statement, which I did not myself see, in the progress of the experiments, and there is much more that can neither be properly appreciated or described except by the person who has observed them throughout, it was deemed preferable that the report should be made by the manager himself, and upon his own responsibility. I therefore requested a particular and accurate report of the facts observed, and which had been mostly noted before, for publication, and which is as follows.

"*Coggin's Point, 7th Sept.*, 1838.

"In obedience to your instructions, I hereby forward to you a statement of the results of the experiments made, agreeably to your directions, of pine and other leaves, applied as top-dressing to young wheat and clover.

"The leaves were collected into heaps as early as possible after falling from the trees. The pine leaves were hauled and put on the nearest portions of our young wheat, in the months of January and February, when the ground was sufficiently frozen to admit of the teams travelling on the wheat without injury, and applied at the rate of from twenty to twenty-three loads per acre, (in carts of 118 cubic feet, and that would contain nearly one hundred bushels,) and were scattered over the wheat as evenly as possible. The benefits resulting to the wheat from this top-dressing, were very apparent soon after the application, and by the 18th of March were strikingly obvious; and from then being some inches taller, and of a deeper green color, than the general crop not so top-dressed, the ground could be easily discerned at a considerable distance. A person standing on one side of a piece of ground so top-dressed, could distinctly trace the exact outlines to where the leaves were applied. The wheat so top-dressed maintained this decided superiority throughout the whole of its growth, and continued very obvious at a distance until the wheat came into ear; but notwithstanding its superiority in every other respect, it was about eight days later in flowering than the adjoining wheat not so top-dressed. The difference in ripening however was not more than four days. On reaping the wheat, the straw was evidently much taller and stronger, than that of the adjoining wheat, the heads appeared to me as being larger, and the grains of a larger and plumper appearance. In this latter respect, it is, however, difficult to form a correct estimate, though as far as I could judge, I am warranted in saying, that the grain did not derive less benefit than did the bulk of straw. The leaves were not applied on one continued portion of the field, but on four different and detached places, and on each with the same very obvious benefits; consequently these benefits are wholly attributable to the covering of leaves, and not to any difference in soil or situation. Nor did these very apparent benefits terminate with the wheat crop; for in this unprecedentedly dry season, when a very large proportion of our clover, sown amongst wheat last spring, is destroyed by the excessive and long-continued drought, the clover on those places top-dressed with leaves looks well, is apparently little injured, and the difference in the greater growth of the clover and cover of weeds, make these spots even now, more obvious than at any period during the growth of the wheat.

"There is one circumstance connected with the above, that I consider worthy of notice. The leaves (altogether of pine) covering the wheat in one place, were extended over a portion of ground much infested with wire-grass. At this time, the ground thus covered with leaves presents a very scanty growth of this pest, while on the adjoining ground there is a very close cover of it. This difference is so evident as to be distinguishable from a considerable distance; and, when closely examined, is found to follow all the little departures from a straight line made in scattering the leaves.

"For a top-dressing to young clover, leaves of every description, convenient to the field, were collected and also applied in the months of January and February, when the ground was suitable for hauling on, at the rate of 32 loads to the acre, (in carts of the same capacity as stated above;) but as it was difficult to have all of the loads equally large, occasional additional loads were necessary, and probably 35 loads were given to the acre. The benefits resulting from this application, were soon very apparent in the earlier and better growth of the clover, though I now consider the covering as having been rather heavy. Adjoining to this was a portion of clover covered in the preceding September with straw. That covered with leaves made an earlier start, and maintained a better appearance than that covered with straw, until after the beginning of May, when the latter evidently gained the superiority, which it maintained throughout the season. The benefits, however, resulting from the application of the leaves, are up to the present time very apparent; both the clover and growth of weeds being better than on adjoining ground which had a liberal top-dressing of farm-pen manure (but of course very light compared to the bulk of leaves) in April and beginning of May.

"In connexion with the above experiments, permit me also to state what has been the result of applying unrotted straw as a top-dressing to young clover early in the fall. In the months of August and September, 1837, all of our wheat straw with the exception of a limited supply left for littering stables, &c., was hauled out and spread on young clover. The clover evidently derived much and early benefit from this covering of straw; and, with a small exception, was the only clover on the farm this season (1838) really worth mowing, which was done for green feeding; and this was the only portion of our clover from which a second cutting could have been obtained, it having longest withstood the effects of the drought. This season I had 126 loads of straw hauled out, as return loads, when hauling in wheat to the thrashing machine, between the 12th and 18th of July, and spread the loads as soon after as an opportunity offered, on young clover. This early, though small application, has proved very beneficial to the clover during the scorching weather that has since occurred. After finishing wheat-thrashing, all our straw (with the exception of a small portion for litter) was hauled out together with the chaff, summer-made manure, &c., and also spread on the young clover; and though only finished so lately as the end of August, there is already a very perceptible improvement in the growth of clover, grass and weeds, compared to that which has not had the benefit of a top-dressing.

"Having simply stated the results, so far as my observation has led me, I leave you to draw the evident inferences, merely remarking that I consider from the result of these experiments, that pine leaves, when they can be got conveniently, as being even a preferable top-dressing, for wheat, to rotted farm-pen manure. What they may want in fertilizing matter, they more than compensate by the warmth and shelter they afford to the young plants both of wheat and clover;

and I would recommend a continuance of the practice, so far as practicable. The practice of applying unrotted straw is, in my opinion, the preferable and most economical mode of applying it, particularly if on young clover. There is only one objection to the practice, which is, that seeds of spelt, &c., are thus applied to the soil in a state favorable to their vegetating. The cutting of the clover in the proper season, and consequently of these foul weeds before they get into seed, would, however, remove this objection. ANDREW NICOL."

It may seem contradictory, as well as strange, that the ripening of the wheat should be retarded by the top-dressing of leaves, which so manifestly forwarded its early growth, and improved the product. But these opposite effects are easy to account for. The leaves not only sheltered the ground from the extremes of cold in winter, but also, in some measure, from heat and drought in summer. Thus, the mechanical effect is to give the benefit of a cooler summer climate—which, to our wheat crop, especially, would be a great benefit. It is known to others, as well as to myself, that Irish potatoes, made without tillage, under a very thick coat of leaves, are of a very superior quality, (as well as in good quantity,) and more like those grown in northern and moist countries, than such as we usually make on ground not thus covered. This thick cover preserves moisture, as well as shade and cooler temperature.

It may be necessary to add, in explanation, that all the parts of the practices referred to, or described in the foregoing statement, were not considered judicious, but were compelled at the time, to avoid still greater loss. For example—though an advocate for top-dressing in general, I do not extend the approval to putting out barn-yard and stable manure as top-dressing in the latter part of summer. Top-dressing with manures so putrescent as to be soon ready to act, (as those from the stable and barn-yard,) ought to be given to a crop then growing, and ready to consume the food furnished by the decomposing manure; and all top-dressings should, if possible, be applied to a crop in its young state and early in the growing season, that it may have the longest time to derive benefit therefrom. Leaves, therefore, should be also applied to clover early; and for an additional reason, viz: that its growth may cover the top-dressing in a short time, and thereby not only protect the leaves from being moved by the winds, but, by keeping them shaded and moist, forward their decomposition, and convert them to food as soon as possible. Of course, it is an essential part of this plan of top-dressing that the growth of clover shall not be taken off, by grazing or mowing, until the previous top-dressing is decomposed by the aid of its shelter and shade. The process designed, is, first to make the leaves, (or any other top-dressing,) to manure and feed the clover—and the next, to make this crop of clover, (turned in green or dry,) manure the succeeding crop of wheat or corn.

No apology will be offered for presenting these theoretical views, sustained, as yet, by so little practical experience. The main object of the communication is to elicit, from other persons, who are much more experienced, and, therefore, much better qualified to instruct, their more practical views, and more profitable results. There are many intelligent and improving farmers among the readers of the Register, who are reported to be successful manurers with leaves on a large scale; and it is earnestly desired by the writer, that such farmers will give to the public, through this journal, at length, their more extended practice, and more valuable opinions. It will be gratifying to the writer of these observations, to aid thus indirectly, if in no other manner, in causing light to be shed on this important subject, even though it should be accompanied by the showing his own views and practice to be erroneous.

EDM. RUFFIN.

DIRECTIONS FOR THE MANAGEMENT OF SILK-WORMS THROUGH THEIR HATCHING AND FEEDING TIME, ACCORDING TO THE MOST APPROVED EUROPEAN PRACTICE.

Translated from the French, for the Farmers' Register,

BY THE EDITOR.

Translator's Introduction.

It is now more than ten years since silk-culture was proposed as a new and profitable direction for a part of the agricultural labor of the United States; and for sixty years, silk has been made, upon a small scale, and with satisfactory profits, in a part of Connecticut. In the last few years, many adventurers have embarked in this new business, in the northern states, or have made preparations for commencing. The successful and known results however, have fallen far short of the expectations excited by the first promises of profit, and the loud notes of preparation for silk culture. Some of the causes of such results, have been stated at length in an article in the last number of the Farmers' Register, (commencing at page 389, volume VI.) It is sufficient here to state the general fact, that the business of selling the multicaulis mulberry plants, offered so much greater profits than feeding the leaves to silk-worms, that the former business has superseded the latter, for the present, and may continue to do so for a year or two to come; and thus, in providing the *means*, the *end* designed seems to be forgotten.

The recent introduction of the most valuable variety of mulberry, the morus multicaulis, will so much lessen the labors of silk-culture, that it may correctly and properly have the effect of extending the business, far beyond its otherwise proper and profitable limits. The actual demand for the plants of this variety, has recently produced a speculating mania, which has enormously enhanced the market value of all the stock now growing in the country; and this fictitious demand, for speculation, and its feverish and improper excitement, are spreading rapidly over all the southern and middle, as well as the northern states where it commenced, and to which, though the least favorable region of our country, schemes of silk-culture had been before almost exclusively confined.

The first effect of this speculating mania, will be to cause a large amount of money to be made by some purchasers, and perhaps much to be lost by others. The mere cultivator of the plants, in no case has yet lost any thing, nor can he lose by the mad speculations of others, or by any decline of prices, unless in suffering disappointment of his own too highly excited hopes of enormous profits. The next, and a very beneficial effect of this mania, will be to spread the multicaulis plants, or cuttings, to every part of the United States; and so great is the facility, certainty, and rapidity of propagation, that wherever a single twig is planted, its increase may, in a few years, serve to feed a great number of silk-worms. The violent fever of excitement, produced by this speculation, is also causing the silk business to attract general attention through the whole country, and of thousands of individual farmers who could not have been stimulated to attempt a new and untried pursuit, by merely the more moderate, even though sure profits, of silk-culture proper. This will operate as an immense benefit to all the country fit for this business; and especially for Virginia and the adjoining slave-holding states, whose circumstances are such as to offer double the profits that can be obtained from rearing silk-worms in the northern states.

We do not pretend to estimate, nor even to have any correct idea of, the profits to be derived from making silk. Those who are willing to trust to such conjectural estimates, may find them in sundry publications issued in the states north of Virginia. But without discussing the claims of any such estimates to be trusted, and without deciding whether the net profit may be $300 per acre, (which some estimates make out,) or the tenth of that amount, (which might satisfy most cultivators here,)—of *this conclusion* we are perfectly sure, THAT WHATEVER MAY BE THE PROFIT OF SILK-CULTURE NORTH OF PHILADELPHIA, MUCH MORE PROFIT MAY BE OBTAINED IN VIRGINIA. And the grounds from which this conclusion is deduced are such as will scarcely be denied, or questioned. They have frequently been stated in editorial articles in the Farmers' Register, and therefore will now merely be briefly repeated.

The first superior advantage possessed by Virginia, is in the warmer climate, which is more suitable to the silk-worms, and far more suitable to the early, long-continued, and luxuriant growth of the mulberry trees, and especially the multicaulis mulberry, which greatly prefers our southern climate.

Secondly, millions of acres of land, worn down by tillage, but still very suitable for bearing mulberry trees, (and which would necessarily be improved by the general system of silk-culture,) may be devoted to this growth; which land is worth nothing to the proprietors, and would not sell for more than $2 to $4 the acre. Yet land, equally poor and unproductive, at first, in New England, if obtained for this purpose, would scarcely cost less than $20 the acre; perhaps, a much larger amount.

Thirdly, the labor required for feeding silk-worms, (which is elsewhere one of the most important parts of the expense,) would cost very little on most farms in Virginia. There are very few farms, on which there are not some slaves who are too young, or too old, or otherwise too infirm, for any common labor, and who, therefore, do nothing, and are a dead expense in their maintenance. These, now worthless and expensive consumers, would be precisely suited, and perfectly competent, to perform all the labors of a silk establishment, under the direction of an intelligent and careful conductor, male or female. Indeed, in many cases, without any hired supervisor, a farmer's industrious wife, with her before useless slaves, might make a crop of cocoons that would sell for half as much money as her husband's surplus grain crop.

Either of these three advantages over northern silk-culture is very great; and, all combined, can scarcely be less than equal to the production of a double net profit. But it must not be forgotten, that to insure this (or even any) profit, there must be applied to these superior advantages, the enterprise, industry, watchfulness, and perseverance, which our northern brethren exercise in all their undertakings and employments, and which requisites for success are generally and deplorably wanting in the southern states.

Entertaining these opinions, we earnestly hope that the now prevailing trading demand for multicaulis mulberry plants, and mania for speculation, may have the good effect of establishing silk-culture, as well as mulberry culture, in the south; and that the solid and certain, though moderate profits of the business, may not be scorned and rejected, as soon as the sales of multicaulis plants come down to a fair price, or cease entirely for want of buyers.

In urging the landholders of Virginia to commence silk-culture, we do not use, as an inducement, the very general statement of its advocates in this country, that the business "is very simple, easy, and requires very little trouble and no particular system." Such is not our opinion. It is a branch of industry promising large returns for a sufficient outlay of care and labor, as well as expense in arrangement and fixtures; but promising nothing to neglectful, careless, and indolent management. It is important, therefore, to the public interest, as well as to that of the individual adventurers in this new and untried direction of industry in Virginia, that there should be as little risk as possible of disappointment and loss, caused by ignorance, and, consequently, the omission of the cares essential to success. Whosoever may commence this business under the belief that it requires no particular procedure, and not much care or trouble, and shall act accordingly, will probably lose his trouble and expense, as little as they may be. But he who takes the opposite view, that much trouble and unremitting attention are absolutely necessary, and is resolved to bestow all that is requisite, will probably have less trouble, in the end, than the most careless conductors, and will reap as much profit as the others will find of loss. It is to guard against this very general error, and to direct new beginners to a course of proper and profitable procedure, that has induced the translation of the treatise which will follow these introductory remarks.

In the several treatises on the rearing and management of silk-worms, which have already been written and published in this country, as well as in the more numerous shorter articles on the same subject, which have appeared in periodical papers, there appears, in one important respect, a general similarity between them, and a marked difference from all known foreign works of high authority. In the latter, the method directed for raising silk-worms, is to preserve, with great care, certain degrees of temperature, with as little variation as possible from the different grades required at different times; and to give food in certain quantities, according to the age and condition of the silk-worms. To be able to command the former object, it is necessary to raise the heat of the laboratory above the average degree of the external air; and to regulate it, by means of fires in stoves or chimneys to raise the heat, and by ventilators, to lower it; and by thermometers to measure and direct the temperature according to fixed rules, which have been established by careful scientific investigation, and long practical experience. All this array of means, even though it may finally conduce to economizing of labor, and to increase the net profits, in a regular and established business, is alarming to new beginners, or experimenters, who are unprovided with any such means for a fully and properly established business; and they have, without exception, readily yielded their assent, and conformed their practice, (so far as there has been any practice,) to the very opposite opinions and directions of those who have written in the United States. These writers concur in the opinion, that the precise rules, and artificial and regulated temperature, of the European method, are altogether unnecessary; that the raising of silk-worms is a very simple operation, and may be done successfully without any particular fixtures, system, or rules, if merely enough of proper food is supplied, and the worms are kept clean enough, and not too much crowded during their growth. Whether it is that these instructions are so reasonable as to carry conviction with them, or that they are more suitable to the natural indolence of men, and their disposition to avoid labor and expense as much as possible in every new undertaking, the result has been, that all who have commenced to raise silk-worms in this country, have adopted, upon the advice of American writers, this more *natural method*, as it may be termed, in contradistinction to the highly *artificial method* of European authorities—scientific investigators, as well as successful practical culturists.

In the reported results of the experimenters and older culturists in this country, so far as they can be gathered from the very limited and imperfect published statements, the returns are said to be satisfactory, and the *prospects* of future success and profit very flattering. But it also often appears, from indirect testimony stated at first, or from making further inquiry, that there were also some heavy deductions from profit suffered in one or more of such occurrences as the worms suffering from excess of heat, cold, or damp weather—of their supplies of food being irregular, and sometimes deficient, sometimes in excess—of irregular progress in their growth, and the whole time being more or less protracted; and from all of such causes, there having resulted great increase of labor and expense in the management, diseases produced and great mortality of worms, and the crop of cocoons, in quantity and quality, being very far below a proper return. If, notwithstanding all these losses, a fair net profit is made, (compared to other branches of agriculture,) or even a fair promise of future profit is in prospect, when the worst first errors shall have been avoided, it is deemed by the culturists as sufficient evidence of the superiority of the simple and natural, over the artificial method.

In this very general opinion, held in this country, by both writers and practical culturists, we cannot, as yet, concur. Our practical experience in rearing silk-worms, it is true, has been limited to a very small experiment; and, therefore, it would be presumptuous either to condemn or approve, without reservation, any practices of which it is admitted we are practically ignorant. But reasoning from all the known facts and circumstances, and in the absence of any certain and accurately reported cases of success in rearing worms on a large scale upon the more natural method, we hold to the opinion, that the method of regular and artificial temperature is not only productive of the greatest gross products from a certain quantity of eggs and of food, but is also the safest and the cheapest. And yet, while presuming thus to object to opinions so generally, if not universally, received in this country, we feel some distrust of our course, not only upon the admitted ground of want of practical experience, but, still more, because of the contrary opinion of the few individuals in this country, whose opinions on this subject deserve much respect. Among the highest, we would place the author of the 'Treatise on Silk Culture,' which was commenced in the last number of this journal, and of which the continuation will be furnished by the author as soon as his engagements may permit. But though willing to pay the utmost respect to opposite views from such sources, and ready to yield to good reasons and proofs, whenever they are brought forward, until so convinced, we shall still maintain the superiority of the method of artificially regulated temperature, and weighed and regulated allowances of food. The reasons for this preference will be concisely stated.

It is affirmed by scientific, intelligent, and also practical silk culturists of Europe, that certain degrees of temperature are most proper for silk-worms in each of their various stages and conditions of life; and that sudden and frequent changes of temperature, even though but of a few degrees, (or much less than occur in the natural temperature of every 24 hours,) is hurtful to their appetite, health, and future product. It is also affirmed, (and that will scarcely be denied by any practical culturist, or even new experimenter,) that equality of temperature, and of other treatment, is necessary to produce equality and uniformity in the successive changes of condition (or "ages") of the worms, and of the duration of their lives; and the inference is inevitable, that, if such uniformity and regularity is totally wanting, the trouble of management will be greatly increased, even if no other evil were to be feared. It is also a settled matter among the highest authorities in Europe, that in every age and successive change of condition of the worms produced from a certain weight of eggs, a certain quantity of food is required, and that they would suffer by any material diminution; and any excess would cause a waste of leaves, be additional trouble in clearing away the litter, and annoyance and injury to the worms by the previous accumulation. Hence must be inferred, not only the benefit and expediency, but the *economy*, both in labor and expense, of knowing how much food is necessary, and furnishing, by careful selection and weighing, that precise allowance for every day, and sometimes for every meal.

It may well be, notwithstanding all the long-continued and laborious investigations of Dandolo, Bonafoux, and other scientific culturists, that the most perfect rules of treatment may not yet have been discovered. Indeed, improvements in this, as in other arts, are made every year, and we entertain no doubt but that the inventive faculties and enterprise of Americans will soon produce as much improvement in silk-culture, as in other old arts, derived from other countries. But still, the principle of the European method will not be the less true, nor less important to be observed in every laboratory, viz. that certain degrees of temperature, and certain quantities of food, are best for each of the various successive conditions of the silk-worms. And if this principle is correct, it cannot be proper or safe to leave the degrees of temperature to be regulated by the chances of the varying seasons; and the proportions of food by guessing, or even by weighing, without knowing the wants of the worms at any particular time.

It is not only the scientific silk-culturists of Italy and France, who, in modern days, have maintained the necessity for the artificial method of heating. The like opinion has obtained in China, the natural region of the silk-worm; and the like end has been reached, (though by very different, and far less perfect means,) in the practices which perhaps have prevailed in that country for thousands of years. In the extracts from the curious old Chinese work, published in the Farmers' Register, it will be seen that artificial, and carefully regulated heat, is directed to be maintained throughout the rearing; and though without thermometers, other means are used to estimate, and thereby direct, the allowance of heat. (See page 232, vol. VI, Farmers' Register.)

If the European rules are not absolutely false—if obedience to them is in truth more beneficial than the natural, simple, or chance-directed methods of rearing silk-worms—there can be little doubt but that, to pursue these, or other proper rules, strictly and carefully, it will be found economical, in labor of attendance, in quantity of food, in the good condition, and more rapid maturity of the worms, in greater security against loss by diseases and deaths, and in the products of all that may live to form cocoons.

But because approving of a very regular system in a large and established silk business, it is not meant that such regularity, or even any particular means, or rules, are necessary to make first experiments, and to meet with great success in the management of a small number of worms. No one need wait to construct a proper cocoonery, or to use any artificial temperature, to raise a few thousand worms. There will be waste of labor in attendance, because of the want of systematic procedure—there will be a waste in the excess of food given—and there may be a protracted or too rapid feeding time. But the worms, by having plenty of room, and plenty of food, may be able to withstand the hurtful variations of temperature, and may produce better cocoons than the average of regular and large establishments. First attempts in feeding silkworms ought always to be on a small scale; and in such, it is of very little importance whether the cost be greater than is necessary, or not, provided the new culturist learns what is proper for future and larger operations. Therefore, we would advise all who desire to make silk, to begin as soon as they can command enough of any eatable mulberry leaves for food, and without any expensive apparatus or regular and exact system; but to conform to a proper system, by the time their business becomes established, and upon a much larger scale.

Under the impressions stated above, we have thought that, in the present general interest felt on the subject, it would be an acceptable service to the agricultural public, to furnish a correct translation from one of the latest European treatises, which may be supposed to contain the received opinions of the culturists of the highest authority, up to the time of the publication. For this purpose, we have chosen Morins' "*Manuel de l'art d'élever et de soigner les vers-a-soie*,' etc., published in Paris, 1828; and have translated the portion which directs the whole treatment, from the first preparation for hatching the eggs, to the end of feeding the worms, when they are ready to climb, and to spin the cocoons. So far as given, the text of the author has been rendered fully and almost literally; as we are not of the opinion that a translator has any right to take any thing from, or add to, the argument, unless when fully showing the fact and its extent, and the cause of the privilege taken. Many parts of the directions are, perhaps, unnecessarily minute, and others (especially in regard to the first preparations for hatching the eggs,) may be totally useless. Of these the reader can judge what is, or is not, useful; taking care to secure the only important object, which is to have all the eggs to hatch together, and at the proper time, and to know the precise quantity hatched.

The portion of the work which treats of the various kinds of mulberry trees, and their culture, has been omitted entirely, because the more recent introduction and rapid extension of the culture of the more valuable *morus multicaulis*, or Chinese mulberry, will nearly supersede all other and older kinds in this country. Also, the portion of the original work which directs the formation of the "hedge," or shelter for the worms when spinning their cocoons, has not been given, because better modes have already been discovered in this country, which, as well as a plan of a good laboratory, will be particularly described in a future article. This translation therefore embraces only the entire hatching and feeding time.

It was not until after this translation had been written, that we obtained the first sight of the manual of silk culture, prepared under the direction of the secretary of the treasury, by order of the House of Representatives, and published in 1828 (Document 158.) It was manifest, upon examination, that our French author, Morin, and the translator, compiler, or author of the manual prepared by direction of our government, drew their instructions for the hatching and feeding, though through different channels, from the same remote source, and the highest authority, Dandolo's work. Of course there is a general similarity, and often indeed identity of substance in the descriptions and directions, as must be expected in any different treatises drawn principally, however circuitously and remotely, from a common source. Still, there are imperfections of form, and manifest errors of version, (in mistakes of the author's meaning,) so great and so important, in the manual published by order of the government, that we had no reason to consider our own labor as thereby rendered useless, or superseded by the prior, though unknown, work of another, who is compiler and author, as well as translator. This combination of characters is the first and great objection to the treatise in question; for though it is manifest that the writer is generally merely a very free translator, from a work of very high authority, yet he often intermixes the instructions or statements of others, and often his own, without distinguishing between them. It follows, that the reader is left to guess, from the context, whether he is receiving instruction upon the high authority of Dandolo, the perhaps questionable authority of others, or from the American writer of the document, whose authority on practical silk culture, like our own, deserves no respect whatever.

The French work from which this translation is made, is one of a number of manuals, upon almost every useful science and art, which, though so many separate treatises, when taken together form the '*Libraire Encyclopédique*.' This general and extensive work was prepared by the combined labors of a number of scientific and literary men, and upon much the same general plan as was conducted the 'Library of Useful Knowledge' in England. It may be inferred of any one of the separate "*Manuels*" which have recently been published under this plan in France, that it presents the latest and most correct information, and what is there received as the best system of instruction in the art of which it treats. This inference was our ground for supposing that this treatise would furnish such instructions as are deemed correct by the best silk culturists of the present time in Italy and France, or those regions of Europe, where the art of rearing silk-worms has been investigated with the most careful and scientific labor, and where the practical results have been the most profitable, and the products the most abundant.—Ed. Far. Reg.

CHAPTER I.

Of the hatching of the silk-worms' eggs.

Among the preliminaries to be observed in the disposition necessary to make for the hatching the eggs, after having detached them from the cloth or paper upon which they have been preserved since they were laid, the most important is to submit them to a temperature a little raised; as much for obtaining them vigorous, and to preserve them capable of fulfilling the end proposed, as to make them hatch altogether. It has not been very long since, for this purpose, recourse was had to the heat of dunghills, of beds, of kitchens and other places; now they construct hot-houses, or warm green-houses, precisely like those which gardeners use for obtaining flowers in winter. From the moment at which the eggs are exposed to this heat, they undergo, all together, the same conditions; and, whatever may be their number, they almost all reach the end desired in the same time. It is necessary, however, to bring to bear unremitting care and attention, and great watchfulness; for without these, the whole brood would be injured or destroyed. Supposing then, that the operator is provided with thermometers, hatching stoves, &c., as will be hereafter described, we will now proceed to speak of the hatching of the worms.

1. To prepare the eggs to hatch, it is of great importance that they should have been well fecundated, and, above all, well preserved, in the climates of France, to the latter part of April, or first days of May. The cloths, to which the eggs are attached, are plunged into common water, and suffered to remain six minutes, that the mucilaginous matter, by which the eggs adhere, may be dissolved. The water is then suffered to be drained from the cloths, for ten minutes, and the eggs are then carefully scraped off with a suitable instrument, [such as an ivory paper-folder, or a spatula,] which may be done with much facility. The eggs are collected, for the purpose of pouring them off successively, and until none are left upon the cloths. We may, in any kind of vessel, do it in half an hour. Before separating the eggs, there is poured over them a little water, which serves to wash them. All which swim on the water are thrown away. For this operation five minutes are sufficient. It has been noticed that eggs which had been laid in a cold and moist temperature, and are yellow, [the mark of not being fecundated,) yet are heavy enough to sink in the water to the bottom of the vessel. All are next poured upon a sieve, or rather upon a thin muslin cloth, to separate the eggs from the water. The eggs are then put into weak wine, either red or white. Some persons afterwards wash them again in another water, and that causes no marked difference; but prudence requires that the eggs should not be left too long in the wine, because it hardens them very much, which retards their hatching. They should be withdrawn from the wine after ten minutes. The temptation of gain alone has induced the dealers in eggs to dip them in high-colored wine, by which the eggs all acquire the color natural to those well fecundated, even when they are worth nothing. This fraud it is necessary for buyers to be guarded against. Whilst in the wine, the eggs should be separated from each other, by being softly rubbed, then stirred, shaken, and poured out with a certain degree of quickness, by which the heaviest, which are all excellent, are easily separated from the light and unfruitful. The wine is separated and the eggs spread upon new dry cloths, until they are completely dried, which requires forty-eight hours. They are then kept in earthen or porcelain plates, in beds of six to eight lines* of thickness, until it is

* The weights and measures stated in this translation are French, and both exceed the American in about the same proportion. Six French feet are equal to six feet and four inches American measure. The French foot, like the American or English, is divided into 12 inches, and the inch into 12 lines. Seven

desired to make them hatch. They must be protected from light and from humidity; and, provided that the temperature is kept at between 46 to 59 degrees [of Fahrenheit's thermometer,] it is sufficient.* All these attentions do not require more than an hour and a half.

2. In order to be able to establish the temperature which suits best for hatching of the silkworms, and in order to regulate it and keep it always equal, it is necessary for the conductor of the business to have at his disposition, and under his eyes, a well constructed and well graduated thermometer. For that purpose, those of mercury are best; but as these, if large, are very dear, M. Lagarde, optician at Paris, (Quai de Gèvres, No. 10,) makes them of spirit of wine, with which it is impossible to commit errors. He has constructed them upon the plan of a physician of Milan, and by instructions of M. Dandolo himself. For "the distance marked from the freezing to the boiling point upon ordinary thermometers is too small, the degrees are too near together, which sometimes causes mistakes to be made. To avoid this inconvenience, I have made, for the hatching-room, thermometers with long scales, the distance from the mark of one degree to another being equal to that of ten degrees of common thermometers. In this manner, I have been able to divide each degree into five fractions, which are easily distinguished, even at some distance. Thus, the least changes of the temperature of the apartment may be perceived. These thermometers have a sign which indicates the point at which the column of colored spirit of wine ought to stop." It will be most proper then, for the purpose of operating in a manner as certain as it is possible to do, to procure thermometers of this kind.†

3. The hot-house hatching room is made of a small apartment, 12 feet square, of which the walls [of brick] are quite dry, and in the midst of which, on one side, must be placed a furnace made of baked earth, or rather of very light bricks. The furnace, or stove, should be capable of being heated with but little fuel, and gradually, in order that it may prolong and preserve its heat as much as possible, or that it may be augmented or diminished, as required, without letting any smoke get into the room. Thermometers should be placed at proper distances, to mark and show that the heat is every where the same; for, if it is certain that all the eggs of caterpillars do not come to the hatching point until surrounded by an atmosphere hot enough to cause the germ of life to be developed, and as silk-worms in our climates cannot certainly obtain the degree of heat which they would meet with in those regions whence they were brought originally, it is then absolutely necessary to supply that temperature, in order to make them hatch together, and that they may be developed in the same manner. There should be arranged, in advance, trays of wicker-work, or hurdles, or moveable frames, or shelves of fir, fixed near the walls by means of cross-pieces, which are implanted in the walls in such manner as not to leave between each two but 22 inches of interval, to place upon them the necessary boxes, constructed of paste-board, or of very thin white wood. The boxes of paste-board should be 8 inches square, with sides half an inch high, for an ounce of eggs to each. When it is desired to place more eggs than this quantity, wooden boxes are provided, of greater or less length and breadth, and with edges more or less elevated, upon which their respective numbers are to be marked. They are placed near each other, leaving between each two an interval of two inches width; and placed always at a convenient height to be examined at the ease of the manager, and for him to be able to move the eggs, from time to time, with a wooden spatula, or shallow spoon, which serves well to stir the eggs, without risk of crushing them.

By means of very sensible thermometers, it will be very easily perceived which are the places in the hatching-room where the heat is lowest; and thus it will be known where to put the eggs of which it is desired to advance or retard the hatching, according as the season may have been favorable or unfavorable to the putting forth of the leaves. By also adding some light tables, upon which may be deposited the boxes in which the worms are hatched, they can easily be changed from place to place on the shelves, at will, and as required.

With one window of large glass, the room will be well enough lighted. The light can do no harm to worms of the first age; and if there is need to moderate the heat, there may be fitted in the sash a moveable pane of glass, which will be opened or closed according to the degree of heat desired to be maintained, or there may be constructed an opening in the door, or, better still, an air-hole or ventilator through the middle of the floor, to be opened or shut by means of a trap-door. When the hatching of the worms is finished, this hatching-room should be put to the common uses of a laboratory, or feeding-room; and in it may be placed worms to be fed and reared, unless subsequent hatchings are desired to be made.

4. To properly order the time of hatching the worms, there will be need to observe the progress of atmospheric temperature, compared to the putting forth of the leaves; and ten days before the worms are desired to be out of the egg, they should be put into the boxes. The time should be noted, and written down, when each parcel of eggs entered the hatching room, with the number of the box which contained each parcel. By giving spaces between the boxes, it will be impossible for one parcel to be mixed with another. The wicker hurdles, or other moveable frames, will be covered with paper in the hatching-room, which should be heated from the first moment to 64 degrees of heat, and so kept for two consecutive days. The third day, the heat must be raised to 66 degrees; the fourth, to 68; the fifth to 71; the sixth to 73; the seventh to 75; the eighth to 77; the ninth to 80; tenth, eleventh, and twelvth, to 82 degrees.

By the signs which we are going to indicate, it will be very easy to know the precise time when the hatching of the worms is to be expected. For

---

pounds French, are seven pounds and twelve ounces American weight.—Translator.

* In the original, the degrees of temperature are marked by Réaumur's scale, which are changed to their equivalents in Fahrenheit's throughout this translation.—Tr.

† The degrees marked on Réaumur's thermometer, the kind referred to in the text, are each equal to 2¼ degrees of Fahrenheit's, which is used in England and the United States. Therefore, the objection made to the small divisions of the degree, does not so much apply here as in France.—Tr.

the eggs, which were of an ash-colored gray, become more or less black; they then pass to violet, then to a yellowish gray, and finally to a dull white; although those eggs which may have been washed in very high-colored wine, will retain the reddish tint to the time when the worms come out.

Often, before placing the eggs in the heated room, to make them hatch, they are made to undergo what is called *maceration;* which is done by enclosing them in little bags, which are placed under cushions, between mattresses, or in woollen coverlets. From time to time they are moved, stirred, and this operation is used only to hasten the hatching of the worms. This method is so much the more uncertain, as it is as impossible to know exactly what degree of heat the eggs may have undergone in advance, as to guess what degree will be necessary to effect the hatching properly. It is not necessary thus to grope our way to an object, in the dark, when it is possible to arrive at it with confidence and certainty.*

In every egg exposed to a state of heat continued for some time, the embryo which it incloses acquires its degree of perfection, and the worm is finally hatched. Indeed, when the eggs have been preserved from one season to another in a mild temperature, there is no need of so great a heat in the hatching-room. They may even hatch spontaneously and unexpectedly, and before the vegetation of the mulberry has yet put forth, if kept in a temperature of 55 to 59 degrees. It is then important and essential to apply the strictest attention; for it is an absolute and totally unnecessary loss when the young worms perish because their food is not ready to be used. To have them to hatch a little too soon is a great injury; but a few days too late is not so. But when the hatching has once commenced, it would be hurtful to the worms to have it retarded, and their developement would greatly suffer.†

It is only at the moment when the egg acquires the dull white color, that the worm is entirely formed, and ready to hatch; it may then be easily distinguished through a magnifying glass. At that stage, there should be placed upon the eggs, covering pieces of white paper, pierced, before-hand, with numerous little holes, made by an awl or needle of suitable size. Or very open muslin may be used instead. To collect the young worms, there must be laid upon the papers some very small shoots of mulberry, with the young leaves at their extremities. These are to be supplied as needed; and on them the worms will collect, (and may be easily removed,) after they climb up through the holes in the paper. These branches also serve to prevent any of the worms from wandering out of their proper boxes.

The worms which climb upon the paper the first day, are often so few in number, that it will be cheaper to get rid of them immediately, and to take care only of the multitude that will come out in the two succeeding days. The first few, if preserved, as they would keep in advance of the great number, would trouble the order to be established for the developement and raising of the others.

For collecting the worms as they are hatched, the small branches of mulberry are to be preferred to single leaves; because the latter might, by their weight, keep down the little worms, and prevent their climbing above; and the greater part might perish from being unable to surmount this obstacle. All the worms which are made to hatch in the manner described above, by means of the stove, possess a force and vigor which is marked by their deep chestnut color. Healthy worms are never reddish, and still less black. When newly hatched, and seen as placed upon the sheet of perforated paper, they appear to form a downy bed, spread out over the whole, in which are distinguished an infinite number of animalcules, with heads raised, which are surmounted with black and shining muzzles. The whole extent of their bodies is then stuck full of very small hairs, with some of a little greater size. Their cuticle, already white, is developed according as they advance in age, and the hairiness disappears gradually. In looking at the worms through a magnifying glass, their white skin is perceived very distinctly at the insertion of the head. Their tails are also seen to be set with a great number of hairs, remarkable for their length.

When the worms are about coming out of the eggs (by aid of artificial heat,) in the hatching-room, there must be placed at suitable distances basins of water, to moisten the inclosed air. This is to prevent a too great degree of dryness injuring their developement. The hatching is also favored by moving the eggs, from time to time, with a wooden spatula; and this movement becomes so much the more useful, and even necessary, as the moment of hatching is approached.

Nothing is lost by these operations; and, by omitting them, the inconveniences caused by the failure, might greatly and injuriously influence the worms during the whole remainder of their short existence. It is even highly to be desired, in the departments of France, where the raising of silk-worms is a general object of industry, that the government, as a means of augmenting and aiding the business, should establish in ever y small dis-

* All these preparatory steps are unnecessary to the young beginner, who does not intend, or is not prepared, to pursue the strict rules of procedure afterwards, through the feeding time. For such persons, almost all the good eggs will hatch just as well, as they stick to the old papers where they were laid. But it should be observed, that all the preparations described above are not for the purpose of making good eggs hatch more surely, but for the purpose of removing the worthless eggs, and the gummy, and every other foreign matter, so as to be able to know exactly the quantity of eggs that will hatch. It is essential to the correctness of all the future operations, to know precisely the weight of eggs.—Tr.

† Dandolo says that the eggs which have been subjected to the process of maceration, or otherwise kept through winter in a mild temperature, will hatch earlier (sometimes 4 or 5 days earlier,) than the eggs kept in a much colder state, though both parcels are subjected to the same heat and treatment in the stove-room, during the hatching process. Hence the importance of previously, as well as during that process, keeping the eggs always at certaln and known degrees of temperature. And as the extension of the time required for hatching, or otherwise the increased heat, is not so objectionable as any uncertainty in calculation, or difference in the times of the worms leaving the eggs, it would seem that it would be best to keep the eggs in the temperature of a deep dry cellar, or an ice-house. Then the time of hatching under a certain temperature, and other like circumstances, would be precisely and always the same, and would be well known in advance.—Tr.

trict, a public hot-house, for hatching in common the eggs belonging to all the neighboring culturists. There is no doubt, but that in thus charging with the business an intelligent man, well instructed in the art of hatching the eggs, it would contribute much to diminish the losses met with in every year's stock of eggs; which losses occur for want of care, or in consequence of the procedure under a blind routine of practice, established by custom, and adhered to through ignorance or prejudice.

CHAPTER II.

Of the small laboratory.

I. If the too great heat, accompanied by dryness of the air which surrounds them, is injurious to the worms, when about to hatch, it is not the less necessary to use the utmost care that they may not be exposed to the least cold, even though it should be for but forty-eight hours. The place in which they are to pass their lives will be proportioned in size to the number of worms which are to be collected there; and it should be calculated in advance what space they will require to occupy, in proportion as they grow larger, and also what space will be required, so as not too much to affect the purity of the air. It is known by experience, that the newly hatched worms of as many eggs as would have weighed an ounce, will occupy a space of 7 or 8 square feet to the time of the first moulting; that it must be extended to 15 or 16 feet to the second, and then to 35 feet to the third moulting. The number of shelves, or of frames or hurdles, should be in proportion to these measures, so that the worms may neither be troubled, nor heaped on each other. The shelves or hurdles should be 22 inches apart, in perpendicular distance, and furnished with paper with upright borders, to prevent the worms falling off. These sheets of paper, as well as of the boxes, should be numbered, in order that no error shall be committed by changing their places, and to be able to attend to the worms in the proper order of their age, until their complete developement.

In the first or small laboratory should be placed two thermometers. It is to be so arranged as to be suitably heated, either by a stove, or by two small chimneys at the corners. The windows and doors will be placed so as to give enough light, and permit sufficient ventilation. The temperature is to be kept constantly at 75 degrees, always from 5 to 7 less than in the hatching room; and progressively according as the worm advances in age and becomes strong. But when the season is cold, and the leaves backward, this heat is lowered to 71 degrees, and even to 68, which is the lowest admissible temperature.

The prudent culturist, says M. Dandolo, has done all that depends upon his care, when he has put the eggs into the stove-room at the time that he saw the sprouts of the mulberry trees well developed, and the weather fair and warm. If, afterwards, the weather suddenly changes to cold, as took place in 1814, it is a highly important power to be able, without danger, to retard the hatching of the worms, and to prolong for some days their two first ages. To obtain this great advantage, there is nothing else to do, if it is the first day that the worms are placed in the small laboratory, but to lower, after four or five hours, to 73 degrees the temperature which before stood at 75, and four or five hours after to 71, and the next day to 68, if that should be necessary. This cooling of the air diminishes the appetite of the worms, gradually and without danger; and by this means are hindered the modifications which, at the 75th degree, would have led sooner to the moulting. At 75 degrees, the first moulting (or casting off the first skin of the worms) would be accomplished in five days; but six or seven are necessary at the reduced temperature. The second moulting is completed in four days at 75 degrees; but requires more than six days, if the temperature is between 68 and 71. Thus it may be seen how the culturist, who is prudent and intelligent, by thus prolonging the two first ages, may gain seven to eight days of time to ward off the dangers of an inclement season. There may be also gained some days in the course of the other ages, as will be seen hereafter. This gain of time for the leaves to grow, as will be readily perceived, may be a very great advantage.

The tables annexed at the end of Dandolo's work show that in 1813 the worms had climbed (to begin to spin their cocoons,) in 31 days; and that 38 were necessary in 1814, to give the time required for the mulberry leaves to ripen. I do not include in these seven days of gain the three of retarding the hatching of the eggs, which might have been used, when delay is required still earlier.

Those persons who will not take this care, and who do not employ any of the means indicated by art to prevent the ill effects of inclement weather, would be obliged to throw away all the worms hatched too soon, or otherwise to strip the mulberry trees so completely, that they would offer leaves of bad quality for the adult age of the worms.

These considerations ought to cause to be generally felt the necessity for retarding, rather than hastening, the putting the eggs to hatch; especially as knowing that, with a good method of taking care of the worms, there is nothing to fear from some days of hot weather; which would have no other effect than to complete the last moultings some days sooner. It is besides certain, that the silk-worms which are retarded choose the leaves suitable to their age, and particularly the ripest leaves, when they are in their last age; the time decisive of the profits of the proprietor, as the worm then acquires all its value.

II. After being hatched, if it is intended to raise the silk-worms in the same place, the little branches of mulberry, scattered over the whole extent of the perforated papers, which cover the little boxes after being filled with worms, are placed in the boxes, upon the little table, (or board, suspended by a wire, or by strings,) which is to serve to transport them to the small laboratory. There, upon other and thicker sheets of paper, numbered and marked like the boxes, should be taken those boxes which bear the same numbers; and the table being placed upon the edges of the hurdles, it will be easy to lay hold of the perforated paper upon which the worms are, and, by means of the the branches which support them, to make them slide off, to the papers placed upon the hurdles. To effect this more safely than with the fingers, (which always endanger the worms,) a little hook, made of wire, may be advantageously used. Care should be taken to place all the little branches at suitable distances, so that they, as well as the intervals between, can be covered equally with leaves; and that the worms may be distributed equally every where. The space which they ought then to occupy, is 20 inches square. The sheets of strong paper ought to be 23 inches long and 21 broad. Of these, the worms should not occupy but 10 inches square, in the middle; and the worms hatched from one ounce of eggs, will therefore require four of such paper sheets. That will suffice until the end of the first moulting; for their extent of surface being four-times that of the little box, there will be no need of moving the worms at all, during that time. The worms should then be fed with a few young and very tender leaves, cut up equally into small pieces, spread equally upon and between the branches, in order that the worms may cover them regularly. And if, by chance, the worms should gather together too thickly in some places, some whole leaves should be put on these places, and after enough of the worms have crept upon them, these leaves should be put in spots the least supplied before. These should be fed as the first; but nothing should be given to them before the sheets of paper are completely furnished, in order that they may all together receive their second meal.

As the whole number of worms designed to be raised together, will scarcely hatch in less time than 48 hours, all the earliest hatching will have gained some increase of size before the last appear, which difference of time is caused by the difference of heat in different parts of the room. But this difference of size will disappear soon, upon giving the most food to the latest hatched worms. They will soon be as large as the older ones.

After all that has been said, it may easily be imagined that there will often be more than three days required to hatch all the silk-worms desired to be obtained from a certain quantity of eggs. For, if the moths, according to the temperature in which they are kept, take from ten to fifteen days to appear, and come out of a certain quantity of cocoons, it is clear that their eggs will also be laid in the same space of between ten and fifteen days. But it would be difficult to explain why eggs which are all put to hatch the same day, exposed to the same degree of heat, do not permit their worms to come out at the same time. It can only be attributed to the peculiar constitution of each egg, and the care taken to confine them to the degree of temperature which suits them best.

It is not the less true that a culturist who has but one little box of eggs, and of which the worms are all to be hatched and reared in the same chamber, ought not to count upon raising the first, and still less the last hatching; not that they are not good, but to avoid the trouble caused by the difference of age. Those persons who hatch many silk worms, and trust their rearing to other persons, ought to keep together all of the same day's hatching, and never mix the first with the last. It is much better to lose the worms hatched the first day, and all the eggs not hatched on the third, than to be troubled with the care of them.

As to those which have to be carried to laboratories far from the hatching-room, it is necessary to place the whole ounce upon a single sheet of paper, in a single square of 18 inches, which is divided into four. By passing the hands beneath the litter to which the worms are attached, and making the fingers penetrate to the middle, the separation is made with facility, observing to divide them as equally as possible.

If these early attentions are neglected, a large proportion of the worms will be lost, even if they do not come [to the different changes of condition] very unequally, and do not contract particular diseases which will be described hereafter.

For the greater facility of transporting to a distance all the worms which have been hatched together by artificial heat, use may be made of a close box, or case, made in the form of a small book-case, with folding doors; but of which the shelves are only two inches apart. The shelves are moveable, and slide in parallel grooves. The case has two handles, or straps, on the posterior face, to enable it to be fixed to and carried on a man's back or shoulders. If such a box or case cannot be readily procured, a common scuttle, *(hotte)* or hamper, may be substituted, taking care that the worms are not exposed to cold. To secure this object, the case should be covered with paper well secured with paste. The shallow paste-board boxes, containing the young worms, will be placed on the shelves, which will leave a space of $1\frac{1}{2}$ to 2 inches above the worms; which will afford room to sprinkle over them tender mulberry leaves, cut up into fine slips. If the journey is to be of much length, it should not be made but in the mildest part of the day, between 11 o'clock and 2 or 3 at latest. In the morning, and still more in the evening, the atmospheric variations would be injurious to the worms.

If the embryo worms experience any damage from the alternations of heat and cold, they will suffer much less when the temperature becomes four degrees colder, than when it becomes as much warmer. As to the light, its influence is of a kind so little marked, that it would be difficult to perceive its effect. If, in the morning, when the sun strikes directly on the windows, the worms are seen to appear in greater quantity, it is solely on account of the increase of heat. If all things were equal in the preliminary dispositions in relation to the brood, it is certain that they might almost all hatch at the same time. And when the worms are to be distributed among other persons, to be fed and reared, they should be given out upon sheets of paper which can contain an ounce, all hatched at the same moment. That will facilitate the proper division of the worms, as hatched on the first, second, and third days. In the stove department, no good eggs can pass the third day without hatching.

CHAPTER III.

The different ages of the silk-worm.

The most important part in the management of silk-worms is to know well, and to maintain steadily and without variation, the degrees of heat, and the temperature, which is most suitable and beneficial to them, during the term of their existence.

It cannot be said that the silk-worm is endangered by any degree of heat of the climate of France, however considerable it may be. Originally from Asia, it supports in its natal country a heat certainly more powerful than any which it can experience in Europe. But it is hurt by any sudden transition from a feeble to a strong degree of heat. It may be said in general, that the too rapid changes from cold to heat, and from heat to cold, are very injurious to them. In their own country, they are not exposed to these vicissitudes; therefore they thrive there very well, and do not require the care which we are obliged to give them in our climates, where the temperature of the atmosphere is so inconstant, that without the help of art we would not be able to have it steady in the laboratories where the silk-worms are fed.

A long course of experience has proved that, in France, the 68th degree of heat [indicated by the thermometer of Fahrenheit,] is the most suitable to silkworms. There are some culturists who have pushed the heat to 73, and even to 77 degrees, and the worms have succeeded equally well. It must be kept in view that it is not the degree of heat, but the too sudden changes, from one to another, which injure silk-worms. If it happens that it is necessary to hasten the growth of the worms, on account of the advanced state of the leaves, (of which the progress could not be retarded,) it should be done by increasing the heat very gradually, so that the worms will scarcely perceive the changes. For they suffer, it may be said, as much by sudden variations of temperature, as they would by the difficulty of breathing, if plunged into nephritic air.

M. Boissier de Sauvages states that being pressed by the advanced growth of the leaves, which were well out in the first days of April, he gave to his silk-worms about 100 degrees of heat in the two first days after hatching, and about 95 during the remainder of the first, and through the second age. They took but nine days for both these ages, or from the hatching to the second moulting inclusively. All the persons who visited the laboratory supposed that the worms could not but suffer by so great a heat, which produced profuse perspiration in a few minutes after entering the apartment. The walls, and the edges of the hurdles were so hot that it could not be endured to keep the hand on them. They felt sure that all would perish. Nevertheless, all went on perfectly well, and, to the general astonishment, the crop of silk was abundant.

He afterwards allowed 93 to 95 degrees of heat for the first age, 89 or 91 for the second; and, what was singular, the duration of the first ages of this raising was nearly as short as the former, of which the worms had much more heat. The cause of this probably is, that there is a limit below which the life of the worms cannot be abridged, whatever degree of heat they may be made to bear. It is true that to these had been given, in this raising, and in the ordinary mode of treatment, a like number of repasts. But what is still more strange, is, that the worms thus hastened, took but five days for each moulting in the two first following ages, although they were then in a temperature of only 82 degrees; while worms which have not been, from the commencement, pushed forward in the same manner, require, at the same heat, seven to eight days for each of these same ages, that is to say, for the third and fourth. It seems as if it were sufficient to have put these little animals in the proper train, for them to obey the first impulse, or the first bend given to them. This early high degree of heat, as given in this case, which produces a rapid growth, gives the worms, at the same time, a vigor and activity which they carry into their following ages; and this is an advantage in the hastened rearing, (that is, pushed forward by heat,) and which, besides, prevents many maladies. This hastened management abridges the trouble and the labor, and releases the manager sooner from the inquietude and sense of insecurity which he will always feel until the cocoons are completed, and gathered.

To pursue this method of using high temperature, it is necessary to pay the utmost attention to the seasons' being more or less advanced, and to the state of growth of the leaves, and that there is no danger of that growth being afterwards checked by cold. On the other hand, if the putting forth of the leaves is backward, and it is followed by heat which lasts long, as may usually be expected, and yet if but little heat is kept up in the laboratory, the worms will advance slowly, and their growth will be prolonged. Still the leaves grow and become harder, and have too much consistence for the worms in their backward state. This then is a state of things in which the growth of the worms should be hastened by continued higher temperature, in order that their progress may be brought up to that of the growth of the leaves, which is an essential point.

If a culturist should determine early to pursue this method, he should set and hatch his eggs some days later than the others. For a still greater degree of prudence, he will wait eight days, and will calculate afterwards the duration of the ages; or rather, he will do better to so arrange his procedure as to have the latest feeding of the worms to correspond in time with the state of full growth of the leaves.*

It has been said above that the worms produced from an ounce of eggs, ought to occupy, in their first age, and to the first moulting, a space of 7 or 8 square feet; of 14 or 15 to the second moulting; of 30 to 35 until the third; and for the fourth and last, the space ought to be at least 83 or 84 square feet. It is also necessary, in fixing the proportion of the quantities of food, given to the worms, to the spaces allowed, not to forget, that until the first moulting the temperature must be constantly maintained at 75 degrees; in the second age it will descend to 73; in the third, the temperature should be from 73 to 71; and from 71 to 68 degrees in the fourth age. These degrees of heat being well established, there should be given to

* This new mode of rearing worms under an unusual and very high temperature, if sufficiently tested by experience, would be a far more valuable improvement in practice in Virginia, and the more southern states, than in France. For, one of the greatest dangers which threatens silk-worms here, is the circumstance of the heat of the weather occasionally rising so much higher than the proper temperature for the interior of the laboratory, that the latter could not be kept down by shading and ventilation. This evil would sometimes happen to the earliest broods; and would certainly attend second or third broods, reared in midsummer, if the usual degrees of temperature directed above, were attempted to be preserved, or if no artificial mode of heating were put in use. This new mode of using great heat would be an admirable and sufficient safeguard against this otherwise certain and great evil; as the heat used would rarely be exceeded by the natural heat of our hottest days.—TRANSLATOR.

the worms then, after their hatching, their arrangement, and their distribution upon the papers, 6 pounds of young mulberry leaves, clean, and chopped or sliced very small. In the second age, the quantity should be increased to 18 pounds, but cut up less finely; in the third, 60 pounds of leaves will be required, still less cut; and, lastly, in the fourth, the quantity of leaves must be increased to 180 pounds, the leaves only cut about to half the size.

However, there may arise some unforeseen circumstances, of which it would be difficult to calculate the effect in advance. But with care, and, above all, with foresight, we may be able to effect the hatching precisely when the trees offer tender leaves, and which will acquire more or less firmness in proportion to the advancement of growth of the worms. If the contrary case should occur, it would compel the loss of the stock of worms, (unless another brood could be procured,) whenever a bad season should greatly retard the shooting of the leaves. If after hatching the worms in good and apparently settled weather, it becomes inclement unexpectedly, it is easy to retard the rate of growth of the worms, at least during some time, and thus to suit their after progress to that of the before suspended growth of the leaves. In the case when the leaves shall not have the requisite qualities, they should further be diminished or increased for the repasts, according to circumstances. For, all the quantities which have been determined by approximation, although confirmed by reiterated experiments, depend almost entirely upon the degree of heat in which the worms are kept and fed. In fine, the economy or procedure prescribed in such cases, does not prevent them from devouring their food with great appetite, digesting it easily, and being preserved constantly in a state of vigor, and excellent condition.

To economize the food and to obtain a crop of cocoons as abundant as possible to have, such are the principal objects which every silk-culturist should have in view. It is known, by experience, that by over-loading the worms with food, there is not only lost the value of the food wasted, but also, by the accumulation of litter, the little vigor which the worms enjoy during some moments of their existence undergoes changes in the time of moulting, which make them pass from having good appetite, to astate of visible languor; and if care and attention are not redoubled, the worms become weak, languishing, sick, and do not wait long to perish. But if, to the contrary, nothing is neglected of the attentions which should be observed, and if the course advised for the best developement of the worms is followed exactly, there will be saved a quantity of cocoons proportioned to the quantity of eggs set, and of the mulberry leaves consumed. For M. Dandolo assures us, 1st. that when 110 or 120 pounds of cocoons are obtained from one ounce of eggs, there will have been consumed very nearly 1650 pounds of leaves; 2d. that when from an ounce of eggs, there is obtained but 55 or 60 pounds of cocoons, there will have been used about 1050 pounds of leaves; in which supposition, there would be required about 2100 pounds of leaves to obtain, from two ounces of eggs, the first named quantity of 110 or 120 pounds of cocoons; 3d. that the 110 or 120 pounds of cocoons obtained from a single ounce of eggs, are worth much more than the same products from two ounces of eggs.

If, as M. Dandolo affirms, from an ounce of eggs, hatched and well taken care of, we may obtain about 165 pounds of cocoons, any deduction from that amount must be considered as so much actual loss; even though the consumption of leaves may have been much more considerable. And if there is added to this loss the injurious influence, which the worms which die in the course of their developement, have upon the survivors, the amount will be greatly increased. The dead bodies increase the indisposition and feebleness of the living; and the more the number is diminished, by want of care, the less silk of good quality will be furnished by the remaining worms, in proportion to the number. It is much to be desired, to remove all doubts on this subject, that there should be established a parallel between the quality and quantity of cocoons produced by a good manner of treating the worms, and the bad, which results almost always from the common routine of practice, and from prejudices, as much as from negligence. A series of tables, which even though but approximations to truth, in a succession of many years, with the meteorological indications of the atmosphere, during the season, would be the best means to employ for the purpose of knowing well the losses caused by the state of ignorance, out of which the managers of silk-worms are not willing to be drawn, whatever efforts may have been made for their instruction and benefit.

The first age.

The first day. Scarcely are the worms hatched and distributed on the squares of paper, as described above, when it is necessary to give them food four times, in quick succession. [$3\frac{3}{4}$ pounds in the twenty-four hours.] For that purpose, the young leaves are cut into slender shreds, either with a sharp knife, or in a suitable cutting box, [constructed upon the principle of a straw-cutter,] and distributed with moderation for the first repast, to be augmented for the second, third and fourth, at the distance of six hours from each other. There is not necessary to the worm but an hour and a half, or two hours at most, for it to be filled and to fall then into a sort of torpid state, during which there is need to watch and keep the temperature constantly equal, and to avoid all changes of hot and cold. For five ounces of eggs, it is proper to place the sheets of worms upon a space of the shelves of 36 square feet, 8 inches; and to distribute over them very nearly 4 pounds of young leaves, tender and cut small; while for one ounce of hatched eggs, it will not be necessary to exceed a pound and a half. A space of twenty inches square suffices also to contain them, so that the leaves will be found eaten through. As the worms as yet reject no excrement, it would be useless to change their place. Then they are so frail and delicate that they should not be touched with the hands. If any of them get too much scattered, they should be carefully lifted with a slender twig, or a large needle, to be put back to their place. For gathering up the leaves scattered too far from the worms, a little broom will be found useful. At this stage of its life, the silk-worm will eat its own weight in leaves in twenty-four hours; therefore, all, for one repast, should not be distributed at once. On the contrary, some should be reserved to give in the intervals, and principally on all the places where leaves appear to be deficient, because strewn there too thinly at first.

The second day, there should be used, in the twenty-four hours, from 6 to 7 pounds of fresh leaves, cut very small; taking care to give a smaller share of the day's allowance at the first time, and all that remains at the last. The squares are enlarged by degrees. Already the aspect of the worm is not the same as on the day before. Its head is larger, and whiter; the color of its body diminishes; its villosities are much less apparent.

On the third day, as the worms now eat very greedily, and as they occupy almost two-thirds of the sheets of paper, there should be given to them 3 pounds of cut leaves at each of their four repasts. In order to satisfy them the better, the first time there should be given but half of the allowance; and if it is eaten in an hour, the time for the second regular repast should be hastened, as well as to give the reserved help of the first repast, in the interval between the two. Without their being entirely covered over, their particular disposition and the quantity of leaves cut to distribute, might alone serve as guides in the matter. Their heads, towards the close of this day, are much whiter; they have taken much more developement; the villosities have almost disappeared; their skins have become reddish-brown; their bodies, and especially their heads, have become shining, with a semi-transparent appearance.

On the fourth day, as the appetite of the worms diminishes, so ought their food to be lessened. There should not then be used but 7 pounds of cut leaves. The first distribution will be of $2\frac{1}{4}$ pounds, and the others will be diminished in proportion to the quantity of leaves of the preceding repast which may remain untouched. The attendant will also take care of the sub-divisions of the intermediate distributions. The sheets of paper are now covered with worms completely. By enlarging the space covered with leaves, at each repast, they are prevented from being heaped upon each other, which might be injurious to them. As from the first part of this day the worms agitate their heads, it is a proof that their outer skin now troubles and overloads them. A great number of them eat but little, and their heads have grown much, and are more shining. By the evening, the worms are almost all still, or torpid, and eat almost nothing. Their bodies are almost transparent; they approach to moulting, and if observed near, and against the light, they appear of a dull white, livid, and yellowish.

On the fifth day, during the whole of it, $1\frac{1}{2}$, or at most 2 pounds of fresh-cut leaves are sufficient. They should be scattered as equally as possible in the course of the day, and only in the places where worms are perceived in a condition to eat. The quantity of leaves indicated, should, of course, be increased or diminished, if, from any circumstances, the worms should need more, or less. There cannot be too much attention paid to the exactness of the distributions, and the economy of the leaves. Towards evening, the worms are almost all torpid or still; some of them are beginning to revive.

The first moulting, [or casting off the first or outer skin,] is now terminated. The worm takes an ash-color. Its vermicular, or crawling motion is very decided; all its rings go and come upon themselves in a manner much more easy and free. The leaves which are to sustain them ought to be gathered at least eight hours before being given to the worms. Leaves may be preserved even for a day or two, in a cool and dry place, sheltered from heat and light.

Thus the first age of the worms is usually complete on the fifth day, without countng in the two days occupied in their hatching, and in collecting and distributing them from the moment of leaving the eggs. To this time they have consumed a little more than thirty pounds of leaves. They have increased to fourteen times their first weight in the space of six days; and increased in length to four or five lines, since coming out of the egg, when they are scarcely one line in length.*

It is especially recommended, to renew, from time to time, the atmospheric air which serves for the worms to breathe in the small laboratory, either by opening the door, or the window, if the season is mild. In the contrary case, of cold weather, the worms are warmed by the furnace, or the fire-places, if there are any, to maintain equal and constant the degree of heat which is necessary to keep them healthy, vigorous, and in good condition. It is even, in some manner, upon this first period of their existence, that depend all the other circumstances which are to bring on the successful termination in view.†

II. *Second Age.*

In arriving at the second age, the worms from five ounces of eggs should occupy a space of 73 square feet of the shelves, or thereabout, and the whole space should be covered with paper. The temperature in which they are kept ought to be from 73 to 75 degrees. To change the litter, it is proper that the greater number of the worms should have awakened; and when they come out of the leaves where they were placed, they ought to be changed immediately. When they are unequal in reviving, it is caused by their not having been distributed according to the rate of their developement; from the greater part having eaten continually, while some have remained under the litter, and all the others upon them, and prevented thereby from breathing freely, or were nearly suffocated under the leaves, where they become torpid, when they should have awakened. In short, the inequality of awakening is owing to the differences of vitality, or the decrease of it, into which the worms have been forced by the negligence of those who should have watched over them. The inequality of awakening, may also be attributed to the first hatched worms not having been put in the coolest places of the laboratory, or the latest hatched not being put in the warmest; or by not having increased the growth of the latter by supplementary distributions of

---

* A line is one-twelfth of an inch.—Tr.

† Throughout each of the ages, the like general increase, first, and then the decrease of appetite, occur, and the same general rules for distributing the food should be observed. That is, during the first part of the age, the meals of each day should successively be increased in quantity, as well as the successive days' allowances, until the maximum of appetite and of food is reached; and then a decrease of each day's several meals, in succession, until the worms again suspend their eating.—Tr.

leaves, to make them overtake the growth of the earliest ones. From the operation of these causes of inequality, some worms are in the torpid state, while some others are eating, after having awakened, and the slowest still eat because they have not arrived at the torpid state. Also, it is as common to see, upon the same sheet of paper, worms of four different sizes, as it is for the last-comers to perish. It is upon going out of the moulting, that they experience the greatest need of air, and of mild heat, equally distributed, to hasten the consistence and energy of their organs, and especially of their muzzles, which, now stripped of their first scaly covering, are again hardening by contact with the surrounding air.

In the *first day* of the second age, and the sixth from the birth of the worm, there should be provided nine or ten pounds of small twigs of mulberry, as tender as possible, and as many fresh leaves, cut small, after being cleaned and picked over.* Also, all the preparations should be made for changing or removing the worms, in order to clean the first sheets of paper upon which they were kept. When they are perceived to be generally awakened, that they agitate their heads, or hold them elevated, as if searching for something, and when some of them have wandered from the litter, the removal should be commenced with those which show most motion. For this purpose, the small mulberry branches, with their leaves, are laid over the papers of worms, with spaces, [one or two inches wide,] left between. Very soon these boughs are covered with worms; then, by means of small moveable boards, very smooth and even, the little branches of mulberry may be changed with the worms on them; and, instead of keeping them as before, in squares, there are placed bands, (or moveable dividing strips of wood,) across the shelf, and are disposed in such manner, that there is nothing to do but to enlarge the two sides of the compartment, [by moving outward the bands, or sliding strips,] whenever there is need of more room; for, at first, the worms ought not to occupy but the half of the space in each small compartment, which is intended for them afterwards.

By means of the little tables, or boards of transport, which are rested with the long side upon the hurdles or shelves, and inclining them, the little branches on them, with their burden of worms, are gently slided off upon the shelves, where they must be arranged in proper order by the hands. Whenever there are seen a few more revived worms, left still uponthe old litter, more of the little branches are put there, to gather up and to remove the worms, as the preceding, to the leaves disposed for them—which must be counted as one distribution; for, in a very short time, there will be nothing of them remaining. The contact of warm air is then sufficient to develope their jaws, enfeebled by the moulting; and far from being inclined to remain upon the litter, where they were, they are seen grouped upon the little branches which have served for their removal, and adhering so closely as to remain heaped together. For the purpose of changing the place of silk-worms, at all times, this is the best method to follow.

One or two hours after the worms have been removed and placed upon the shelves, there should be distributed to them three pounds of leaves, cut small, as before. In the cases where the worms, though crowded upon the stripped branches, may leave vacant intervals between them, there should be placed on these intervals other leaves, so as to make them extend themselves, and occupy the whole space designed for them, after this first repast. The two others, for this day, are to be given at intervals of six hours from one another.

The removal of the worms to the other shelves, being finished, the first sheets of paper which they occupied must be rolled up, to be carried out of the laboratory. For what remains on them is only excremental matter, and the cast skins, mingled with the remains of the leaves fed on since the birth of the worms. Out of thirty pounds of leaves given, it may be counted on that twenty-two and a half will have been completely digested.

In the *second day*, there should be given thirty pounds of cut leaves, to be divided into four portions, and given at intervals of six hours. The two last distributions should be rather larger than the first. The enclosing strips should be enlarged, and moved to the compartments this evening, so as to permit two-thirds of the whole space to be completely occupied. The worm is now of a clear white color; its head is a little larger. They are dispersed, as has been said, by taking them upon little branches, to bear them to the places where there are too few. It is very important that they should be equally spread over the surface.

In the *third day*, the two first meals should be more abundant. There should be used for this day thirty-three pounds of leaves, cut small, taking care to proportion them according to the wants of the worms. For, towards the end of this day, not only does their appetite lessen, but again they hold the head high, they cease to eat, and fall into a marked state of torpor. Their spaces are again enlarged, so that they now have four-fifths of the whole.

In the *fourth day*, there should be distributed to the worms only nine pounds of leaves, picked, cleaned and cut, observing always, to divide them equally and lightly. When once completely torpid, it is not until the next day, and after the termination of their second casting off their skins, that they will awaken. Then their second age will be entirely completed. In calculating their consumption of ninety pounds of cut leaves and little branches, with what remains of the litter, it is seen that it required twenty-one pounds to feed each ounce of worms, considered separately. During this second period, the worms are become of a clear gray color; the hairs are so shortened as to be seen with difficulty; the muzzle, which had been black, has whitened, and, immediately after the moulting, is soft, soon to retake its first form

* It is obviously an important saving of trouble to pick over the leaves carefully, before chopping them, and to remove all dead leaves, and other parts, or foreign matters, which are unfit for food. For even if none of these matters are otherwise hurtful to the worms, their presence will prevent the quantity of food given by weight being accurately estimated, and moreover will serve greatly to increase the mass of litter and filth, and will cause more labor to separate it from the worms, when removed at last, than would be required to avoid distributing them with the clean leaves at first.—Tr.

and first color. It hardens even according as it makes progress, and according to the need of having food a little more solid. Upon the back are seen two curved lines, opposite to each other. The worm has grown in length two lines, and already it has need of a much greater quantity of air to respire at its ease. Its respiration, greatly increased, exacts a more frequent renewal of the air, either by opening the windows when the outer air is mild, or by opening the door, or the smaller opening made in the door, and until the thermometer shall have sunk two degrees.

III. *Third age.*

For the *first day*, the preparation for feeding should consist of 15 pounds of clean-picked and fresh leaves, less cut than the preceding, to which should be added as much in weight of small branches. The worms of five ounces of eggs will now occupy 174 feet of the shelves, which should, as before, be covered with paper. They will be kept in a temperature ranging from 71 to 73 degrees. They must not be changed to new places until it is seen that they have almost all come out of their torpid state, (which usually takes place in 24, or 30 hours at most,) by a movement of turning which they make with the head. Agitating the air cannot hurt them, though, when breathed upon, they seem to experience a disagreeable sensation. To remove them, after this moulting, there should be used the same procedure and precaution as before. If the spaces which silk-worms should occupy, in their different ages, are correctly calculated, there will be nothing more easy than to lift them, to clean them, and to dispose them anew upon hurdles or frames, where they are left until they have completed their moulting, at a sufficient distance from each other. They eat now with the greatest facility. Their litter cannot injure them in any manner. Their first repast will consist of the 15 pounds of little branches with all the leaves growing on them, which, when eaten, will be replaced by 7 or 8 pounds of other leaves, equally distributed by means of the broom. The most essential point, then, for him who is charged with the care of silk-worms, is to distribute them equally upon the shelves, or the hurdles, as well as to watch over the just distribution of the leaves with which he feeds them; for to furnish too great a quantity would be an absolute loss, and the excess would serve but to augment the litter, which would lead to its certain fermentation, and might be the occasional cause of many diseases.

This day will be terminated by a distribution of 7 pounds of leaves. Or if they should not be wanting, they should be kept to add to the supply for the next day.

It may take an hour, or two at most, to change the worms which are to cover 174 feet of shelves or frames. Always as soon as possible after removing the worms, the litter should be rolled up with the paper, and carried out. Before getting rid of the litter, search should be made in it whether there may not remain there some torpid worms, which the contact of the open air will reanimate much sooner than that of the laboratory; and after having placed them upon some little branches, they should be brought back to the others. As to these last roused, they should be kept on separate shelves, in the warmest parts of the laboratory, and allowed plenty of room.

From this time the consumption of the worms is very great. To give them the leaves easily, there should be provided square baskets, shallow and wide, with handles, by which they can be suspended on hooks, any where, and may be emptied, using both the hands together, of the leaves which they contain, to be distributed at will, whether at the height of the individual, or upon the more elevated shelves, by aid of little stools, or very light ladders. When the worms shall have eaten three or four of these meals, it will be perceived that their size is sensibly increased, that their color is brighter, and at the same time that the muzzle is lengthened.

On the *second day*, there must be provided 90 pounds of picked and cut leaves, of which the two first meals will be smaller than the two last, because that by the evening the appetite of the worms is increased. The space occupied by them also should still be enlarged gradually.

On the *third day*, there must be distributed to the worms seven pounds of cut leaves more than the quantity of the previous day; observing to give the greatest shares at the two first meals. The distribution of food for the evening ought to be less, because the worms are then losing their appetite. They have now grown much in size, are becoming white and transparent, their heads are lengthened, and the circumvolutions which they make with it, precede the moment when they are going to become torpid again.

On the *fourth day*, the food will be only 52 pounds of leaves, because the appetite of the worms is much less. The greater number are already torpid. The share for the first meal should be the largest, and for the last, much less. The leaves should not be spread but in the places where they are needed, and the want of them is perceived. In case there are found on the same shelf some which still require food, there need be no fear to give it to them, that they may more quickly reach the state of the others. Excellent effects are obtained from these intermediate meals.

For the *fifth day*, the distribution of cut leaves should be only 27 pounds in all, and shared only to the places where it is seen that food is wanted. Since the day before, there may be seen throughout some of the foam or slaver of silk, which the worms have rejected. They are seen now to seek to go to their sleep, in free air, in the dry places, and holding the head continually raised; and those which are compelled to remain on the litter, elevate their heads above it, maintaining the same position. At the instant when they are passing into their state of momentary torpor, they evacuate all that they have within their bodies; the intestinal canal is then distended by a lymphatic fluid, yellowish and transparent; the outer skin becomes wrinkled and dry before being cast off. During all the time of the moulting it is necessary to agitate and renew the air of the laboratory, taking care to keep the temperature at the previous degree of elevation.

On the *sixth day*, the greater number of worms are disposed to revive from their torpor. Their third age is now completed. They have passed through it in the space of six days, consuming 300 pounds of leaves and small branches; which is nearly 69 pounds to the ounce of eggs. Their muzzle is lengthened, and jutting out; from black, which it was before, it has become of a reddish-gray; the head, the body, have sensibly increased in size; the body is covered with wrinkles, as well as the head, and the skin no longer appears hairy. The general color borders upon yellow orange. All their feet towards the posterior end being developed, permits the worms to cling strongly to whatever they touch and eat. There is even heard a slight sound, which they make in moving from one place to another, which ceases when they fix themselves, and which becomes more strong as they grow older. Since the second moulting the worms have gained six lines in length, and have increased their weight fourfold.

IV. *Fourth age.*

The space which the worms should now occupy is of 412 square feet, and the temperature required for them is from 68 to 71 degrees; and even should it rise to 73 degrees, or higher, there will be no danger, provided the air be renewed from time to time, by opening the doors and windows, [keeping closed the venetian blinds.] By this means, the litter, is almost always moist, is hindered from entering into fermentation, and disengaging exhalations which would be extremely injurious to the worms. Many times entire broods have perished for want of such precautions being taken.

The hurdles should not be changed until almost all the worms have got over their torpor. Those first revived should be put in the places the least hot, and the last where the temperature is highest. The thermometer will easily direct to the proper places for both. These attentions are even indispensable, when it is required to make the worms climb (to begin their cocoons,) all at one time.

The third moulting being thus ended, the worms should be removed, that they may no more be disturbed, to the great laboratory; where they should have, that they may be at ease, 920 square feet of surface on the shelves, whether in one large apartment, or in several smaller, but contiguous, for the greater quickness and ease of the services to be performed. However, as at coming out of the third age, they did not occupy but 459 square feet, it is necessary to mark off the spaces in advance, and fix them by proper bands, or strips, which may be moved to enlarge the spaces gradually, and at will. There result from this arrangement, essential in every rearing of silk-worms, 1st, that the litter, (which it is not necessary should be taken away in the fourth age,) increases insensibly, and as it has very little thickness, there is disengaged from it no marked or hurtful odor; 2d, by such thin scattering of the leaves, it results that they are more equally eaten; they have no time to fade, and still less to be spoiled; 3d, that the worms, being suitably dispersed, eat much better, and at their ease; it is much easier for them to move themselves; and their perspiration, as well as their breathing, is performed in a manner which is extremely beneficial.

For the *first day*, which is the sixteenth of their existence, there should be provided for the worms thirty-eight pounds of small branches, and sixty pounds of leaves cut only to about half sizes, by the cutting-machine. When it is necessary to remove the worms, there should be spread some of the little branches of mulberry over two hurdles only at a time; and when these are filled and covered with worms, they are transported on the boards as before. The little branches may be substituted by numbers of the whole leaves tied together by their foot-stalks, to be spread out to receive the worms, and to be lifted and moved when filled with them. Two persons being charged with this part of the operation, and two others conveying the boards with the loaded boughs, or bunches of leaves, as quickly as possible to the places destined for the worms, will soon effect the removal. If there remain some which are still torpid, they must be collected and put in a separate place.

There are then distributed to the whole number thirty pounds of leaves, all along the bands, in strips, which are kept still at some width. The scattered leaves are gathered to the places where they are wanted, by the little broom. Soon all the silk-worms are disposed equally over the frames; and if the leaves are still cut for them for three or four more days, it is to induce them to eat quicker, by the leaves exhaling a stronger smell, and presenting many more surfaces to the mouths of the worms. The second meal being ended towards evening, when it is entirely consumed, the worms become whiter, have much more strength and vigor, and their movements are more marked.

For the *second day*, there will be used 165 pounds of leaves, still cut, though but slightly. Of this, the three first meals will be moderate, and the last ample. The space which the worms occupy is gradually enlarged, as they now increase in size rapidly. At the same time they take a much whiter color.

For the *third day*, there should be given in the four meals 225 pounds of leaves, cleaned and cut into large pieces. The quantities for the two last meals should be much greater than the two first.

On the *fourth day*, there should be fed 255 pounds of leaves. The three first shares should be about seventy pounds each, and the last, forty-five. Towards the close of the day, the silk-worms are about 18 lines in length; and they are still whiter than on the preceding day.

On the *fifth day*, as the hunger of the worms will have sensibly lessened, 120 pounds of leaves slightly cut, will be enough. The first distribution will be the most considerable. The worms almost all become still or torpid. The other distributions of leaves should be made only on the places where worms, not yet torpid, are seen. Generally they have increased in length two lines more.

For the *sixth day*, no more will be required for feeding than thirty-five pounds of leaves divided and given according as the want of them is perceived. By the evening, the worms will have evacuated; they are become much smaller; the green color has disappeared; they are covered with wrinkles which are scarcely visible.

In the *seventh day*, the silk-worms accomplish their fourth moulting, and come out of the torpid state. During the last 7 days they have increased in length six lines. They are now of a grayish and reddish color, deeply tinged, and their augmented weight is quite visible. During all the time of this age, it is absolutely necessary that the air of the laboratory should be kept in a state of continual purity. Thus it must be renewed as often as is found necessary, either by opening the doors, the windows, the air-holes, or the ventilators, whenever the outer temperature is nearly the same with that of the laboratory; and, in the contrary case, by making fires in the chimneys with very dry combustible matters. The purity of the air, in which the worms are continually kept, is of the first necessity, to maintain their existence in a state of sustained vigor, and to prevent the contracting of diseases. The persons occupied in attending to the worms, ought also not to suffer any disagreeable sensations in breathing the air of the laboratory; and if they experience any such sensation, or affection troublesome to the organs of the chest, however little it may be, they should immediately use all the means at their disposal to renew the air which surrounds them.

V. *Fifth age.*

In the *first day* of the fifth age, which is the twenty-third of the life of the silk-worms, their fourth moulting is finished, and almost all are again aroused from their torpor. They ought now to be kept at a temperature of 68 to 71 degrees. Spread out upon 918 square feet of the shelves by a sufficient number of persons, this operation ought to be completed in eight hours at most. The first distribution which is necessary to them, amounts to ninety pounds of small branches, or whole leaves, and as much of others, but after having been cleaned. The branches must be spread out upon four or five hurdles. As soon as covered with the worms, the branches are carried to other frames, in the middle of each of which there is left a vacant interval of more than half the size of the frame. The frames from which the worms are thus removed, are then cleaned; and all the worms which may be still torpid, and left on them, are to be collected together, as directed formerly, upon separate shelves, in the warmest part of the laboratory, and taken such special care of, that they may arrive at the latter conditions in the same time with the others.

If attention has been paid in first placing the worms on half of the shelves—if the interval in the middle of the hurdles has been well preserved—in two changes, all the worms will be found equally distributed through all the interior of the laboratory, and in a suitable manner. The leaves of the branches used will have served for one of the meals; what remains of the leaves and other branches will be given after an interval of six hours; taking care to bring together with the little broom all the leaves too much scattered, and to disperse the worms which may be too much clustered together, into places where there is space to spare. At the last meal, which will be but of forty-five pounds of leaves, the boards should be again moved, to allow more space to the worms. All will then appear to enjoy a degree of vigor sufficiently well marked. Fresh air should be given by the windows, if the outer temperature should be nearly equal to that of the laboratory, and especially while the cleaning is done. Slight attention to the thermometer and hygrometer will serve to show what changes may be made in the air. *

In the *second day*, the spaces should be again enlarged, and there should be given to the worms, 270 pounds of clean leaves, divided in the following manner: fifty-two pounds for the first meal, and ninety-seven for the last; [the balance of 121 pounds, for the two middle repasts.] It is plainly seen, towards the end of the day, that the worms are much whiter than the day before, and that they are rapidly tending to their further developement.

On the *third day*, there should be spread over the worms, which are now very voracious, 420 pounds of clean leaves. The first meal will be of 77 pounds; the second and third, of more than 100 pounds each; and the fourth will take 120 pounds. It is very certain that they can eat much more; but the quantity indicated here has always appeared sufficient to keep them vigorous, when care is taken to continue to manage the bands, and enlarge the spaces in proportion to the increase of food. The worms are now 26 and 28 lines in length, and their whiteness is also much increased.

On the *fourth day*, the quantity of leaves to be given should still be increased. The first meal will be of 120 pounds, the two following of 135 each, and the last of 150. The appetite of the worms is still greater, and they have, in very little time, reached a length of about 3 inches. They consequently require much food, and there is nothing to be feared in giving to them the 540 pounds of leaves.

On the *fifth day*, the provision of leaves ought to be augmented to 810 pounds; of which the first distribution will be 150 pounds, the last 210, and the two intermediate meals, 220 and 230 pounds of leaves. It is also often of necessity to make some partial distribution of leaves, in the intervals of time between the greater, especially in places where it is perceived that otherwise the worms would be too long without food. If the frames need clearing, it should be done at the close of this day, or early in the next, in not distributing the leaves but upon four frames at once. But as the worms are no more to be changed, or moved away from the frames they occupy, the following method for clearing will be followed. In a little time after the leaves are spread, and as soon as they are covered with the worms, they are taken and placed as quickly as possible upon the little tables, or moveable boards, used for transporting, which are leaned for that purpose on the edges of the frames. The litter is then immediately taken up from the frames, and thrown into the baskets. This done, the worms are replaced as before on the frames; and so on, successively, with all the frames to the end.

With whatever quickness the litter may be changed, the operation is always too long; and, therefore, it is necessary to feed the worms first cleaned, so as to leave no interval, and that the meals may be shared equally between the last and the others. The manager must look well to the state of the interior of the laboratory, in respect to

* A hygrometer is any instrument for measuring or comparing the different degrees of moisture in the atmosphere. If no better can be conveniently provided, a very simple but sufficient one may be made with a long twine suspended from one fixed end in the laboratory, and having a weight at the other end, to keep it well stretched. The length of the string will contract in proportion to the degree of moisture in the surrounding air, and extend in proportion to the dryness; and the changes will be readily shown in a graduated scale, along-side or over which the weight will rise or sink, as the string contracts or expands in length. As the amount of variation will be in proportion to the length of the string, and, of course, the size of the degrees, marked on the scale, and the accuracy of the scale, the length may be made as great as desired, and yet the whole kept within convenient limits, by passing the string backwards and forwards, and horizontally, over the rollers of sundry small pully-wheels, which will yield freely to the slightest impulse of the string.—Tr.

humidity, to the atmospheric heat, and to the state of the air which is contained, in order that the worms may be preserved in their condition of vigor acquired by the progress of age. It is scarcely necessary to say that the litter heaped in the baskets should be carried out of the house immediately; and that in the handlings required for changing the leaves covered with the worms, great care should be taken not to wound or hurt the worms with the fingers.

On the *sixth day*, without being an eye-witness to the circumstances, it is scarcely possible to have a correct conception of the voracity with which the worm seizes on every thing presented to it. It even attaches itself to the fruit of the mulberry tree, which by chance are left among the leaves. This day, there will be distributed in four times, 975 pounds of leaves. The last meal should be much the largest share of the four. It must not be forgotten to add more leaves in all the places where the worms appear to need them, between the times of the regular meals, in the prolonging of which the worms now gnaw and tear all that is given to them. They are now 3 inches long; and if they are very white, soft to the touch, and of a velvet smoothness, they may be considered in the most perfect health.

The *seventh day* is that in which the worms complete the greatest length which they can acquire, and arrive at their full weight. If no more than six worms are required generally to weigh an ounce, they are then in their highest state of vigor. There will be distributed to them, in meals decreasing in quantity from the first to the last, nearly 900 pounds of leaves; and giving intermediate supplies, if required by circumstances. Towards the evening, their extremity, which had been white, assumes a yellowish color; it is said then that the worms are "*ripening*." Their mastication perceptibly lessens; it is the same of their weight, and of their length; they discharge a considerable quantity of excrement; there is a continual exhalation and evaporation rising from their bodies; and if they have, in about seven days, doubled their length, they are now going to decrease as fast.

On the *eighth day*, as the appetite of worms is much lessened, there will be need of no more provision than 660 pounds of leaves, which should be chosen as good as possible, and from the oldest trees. The first share should be the largest, say 200 pounds, and the following meals be lessened successively. And that the worms may ripen together, still, as before, some intermediate distributions should be made, wherever they are seen to be needed. The yellow color of the worm now extends from one ring to another; they become shining; are no more greenish; they diminish perceptibly in bulk; they seek the edges of the hurdles to evacuate all that ought to be discharged from their bowels. In proportion as it is perceived that they approach maturity, and, especially, if there is too much moisture, the litter should be removed, as quickly as possible. Strict attention must be paid to the state of the atmosphere in the laboratory, and to the removal or correction of every thing that can be injurious in any manner to the worms.

On the *ninth day*, the thirty-first since the birth of the worms, the provision of leaves will be only 435 pounds, to be distributed throughout, and wherever there is more special want. The worms are becoming more yellow, the surface on the back is more shining, the rings are orange, the muzzle is more clear. Currents of air, and exposure to sudden changes of temperature must be guarded against; though it may seem that the healthy and vigorous worms may suffer no remarkable inconvenience, even if exposed to considerable inclemency of the weather.

The worms, from their hatching to this time, have grown to forty times their first length, and, in a month, have increased to nine thousand times more weight than they were when just come forth from the egg. The most active period of their short life is the space of nine days comprised within the fifth age. There is yet, however, need for great watchfulness over the worms, that they may arrive safely at perfect maturity, which will not be until they throw off the skin that now covers them and change to the *chrysalis* form, losing, at the same time, half the bulk and weight of their bodies. The transverse bands reappear upon their backs, and the scaly prolongation of the muzzle becomes blackish, brilliant, and very strong. Their whiteness is much more decided that it has been before; and to the touch, they have the firmness of flesh, as well as velvet softness, especially when healthy and vigorous. At this time the worms should be kept not only in a warm enough temperature, but in air continually renewed, if for no other purpose than to favor the evaporation and aid the removal of the perspiratory fluids, which are transuding from the worms continually, during the last part of their existence in this form.

In the last period of the fifth age, for the formation and perfect completion of the cocoons by the uninterrupted spinning of the silk, until the moment when the worm becomes a chrysalis, it is necessary that the silk-worm should have its body composed of but two substances, the one the silk material, and the other purely of animal matter; and that the intestinal canal should be evacuated of all the excremental matter which it contained. It is therefore necessary to keep the worms in the most perfect state of cleanliness, and also to continue to give them leaves at the same time, not only to finish this day, but still to wait some twenty-four hours more for their maturity to be fully completed; which will be known by the following signs:

On the *tenth day*, the thirty-second from their hatching, when fresh leaves are given to the worms, if they climb upon them and do not eat—if they keep the neck stretched and the head raised, as if searching for something—if they are transparent, and of a fine yellow color—when they raise themselves upon the hurdles where they were supported, crawling slowly, and when they reach the edges, endeavor to go farther—when their rings disappear, and their greenish hue is entirely changed to orange-yellow, the neck becomes wrinkled, and all the body becomes soft—finally, if in placing one of the worms in the hollow of the hand, and looking at it facing the light, it is perceived that the light shows through it—then immediately every thing should be disposed to favor the immediate climbing of the worm, for the purpose of their beginning to spin their cocoons, lest any fruitless efforts in searching for places to spin, may exhaust some of their silk.

For the Farmers' Register.

TREATISE ON THE CULTURE OF SILK.

BY GIDEON B. SMITH.

No 2.

The laboratory, fixtures, silk-worms, &c.

The laboratory, or building in which silk-worms are to be raised, must be of a size proportioned to the number of worms intended to be kept. As to its form and structure, no precise rules can be given, nor, indeed, are any such necessary. Probably no two persons in Europe have laboratories precisely alike; and this fact goes to prove that no particular construction is necessary. All that is required, is, that the room should be of sufficient size to accommodate the number of worms intended to be kept; that it should be provided with fireplaces or stoves, for raising the temperature when necessary, and drying the air, and with ventilators in the ceiling, and windows on all sides, for the purpose of ventilation and light. I would, however, recommend wooden, instead of brick or stone buildings, as they are more easily managed as to temperature, than the latter; and, in damp weather, do not condense and collect water from the atmosphere so much. In a large room, three or four small stoves at the extreme ends and sides are very useful in severe cold times, and also in very damp weather. Ventilators may be very usefully made at each side of the room (if the house be a frame,) by leaving a space one or two feet deep, and the whole length of the room, and reaching to the floor, occupied by long shutters, hung by hinges on the upper sides. In ordinary warm, dry weather, these shutters may be raised, more or less, as desired, and thus the room kept well supplied with fresh air. During cold or damp weather, the shutters will, of course, be kept closed. A large room ought to have several vents for the escape of foul air, in the ceiling. These may be nothing more than ordinary trap-doors, two feet wide and three feet long, with shutters to close them at pleasure. When these are opened, and the ventilators at the sides also open, a free current of air will be kept up through the hurdles, and thus the laboratory will be kept free from impure air. They will be found particularly useful after a time of rainy or damp weather, during which it has been necessary to keep the room shut up. I have found *fire* particularly useful in these damp times, (though the temperature was sufficiently high of itself,) in purifying the atmosphere in the room. I generally make a brisk blaze with light-wood or shavings in the fireplaces or stoves. It has an admirable effect, not only in expelling foul air, but in enlivening the worms—probably by drying the damp air. I have found much more use for fire, during such times, than I ever have on account of cold weather. Indeed, we seldom have weather cold enough to do harm at the season of feeding silk-worms; though we do sometimes, however, it is of short duration. Permit me to make one remark here, on the effect of temperature on silk-worms. I would not be understood as saying or believing, that the temperature could be neither too high nor too low for a profitable result; but I do say, that silk-worms are not affected more than other insects, by its variations. Indeed, I am pretty well convinced, that ordinary variations of temperature are as beneficial to the constitutions of silk-worms, as they are known to be to other animals. *Extremes* only do harm. Do we not find that a continued sameness of temperature, especially if warm, is debilitating to our own systems, and to those of all other animals? Look at the people of the tropics. The temperature there is seldom higher than with us in summer, but it is more equable—always nearly the same. I need not allude to the effect of it on the constitutions of the people: their imbecile, languid, lazy, spiritless characters, are proverbial. As we go north, where the variations of temperature are the greatest, we find the constitutions of men and animals the most robust. Indeed, variations of temperature, and the agitation of the atmosphere in the form of heavy winds, appear to be beneficently provided by the Creator, for the well-being of all his creatures. Why, then, are silk-worms supposed to be exceptions to this rule? I cannot believe that they are; and my experience supports me in the belief of their being, like all other animals, only injured by extremes.

A pretty good calculation may be made as to the size of the room required, from the fact, that a room eighty feet long and forty wide will accommodate one million of worms. Instead of one room of that size, four of forty by twenty, I think, would be preferable, as being more conveniently managed, and being better adapted to a proper *division* of the worms, which may then be separated, each day's hatching being placed in a distinct room. The temperature of the rooms can also be more easily regulated, though possibly at something greater expense of fuel.

In large establishments, a hatching-room will be useful. This need not be large—say twelve by fifteen feet. It should be made close, with a couple of windows, capable of being perfectly closed by shutters at pleasure. A good stove should be provided, capable of raising the temperature to summer-heat, when required. This room may be conveniently used, also, for killing the chrysalis in the cocoons, as will be hereafter shown.

Another room will be necessary for the accommodation of leaves, a good supply of which for a day or two a-head, should always be provided, that no lack of a supply may occur during rainy weather. A loft over the laboratory, or a room in the basement, may be very conveniently used for the purpose. In a basement, leaves will keep fresh for three days, but they should not be left in compact masses, as they are apt to *heat*, from spontaneous fermentation. It is proper that they should be occasionally stirred and shaken about, to prevent such an event.

The fixtures of the laboratory, are convenient hurdles or shelves, for the accommodation of the worms while feeding, and spinning their cocoons. The best form and construction, are those first adopted by me, and which I believe are now in general use. They are two and a half to three feet wide, and four to five feet long. The size may, of course, be varied at pleasure, without detriment or inconvenience. The size mentioned will accommodate about 500 worms, when ready to spin cocoons. They are made like the outside frame of a window-sash, with a floor of netting.

The netting is now woven in the north for the purpose, and only requires to be tacked to the frame, well stretched. Formerly it was necessary to make the netting ourselves, which was done by perforating the sides and ends of the frame with a broad awl five-eighths of an inch apart, and inserting good skein twine first, length-wise, until it was filled, then crosswise, weaving it by passing it over and under the other twine alternately, and drawing it quite tight. The twine will be about five-eighths of an inch apart each way. It is of some importance, that the twine should be *tanned*, by immersion in a tanner's vat, for a few hours, dried, and then thoroughly washed, to remove any remains of the tan that may be on it. This ought also to be done with the prepared netting, if that be obtained. The utility of the tanning is obvious: it prevents rotting, to which the twine is liable, from the dampness of the filth. The netting should also be put on the frames in dry weather, because the twine is then at its greatest expansion; and if put on in that state, is not so liable to stretch and *lag*, when loaded with worms and food. Another frame of the same size, is to be covered with *paper* or muslin, to be placed immediately under the net frames, in the *stands*. These latter are used for the purpose of catching the ordure and filth that falls through the netting of the hurdles. They may be placed two or three inches below the hurdles.

The STANDS, for the support of the hurdles, are simply upright posts, made of three or four inch joist, firmly fixed to the floor below, and to the ceiling above, two feet apart one way, and just far enough the other to permit the free passage of the hurdles sideways between them. Pieces of wood are to be nailed to each two posts to support the hurdles, at about twelve inches apart. I had mine only nine inches apart; but I think they are better at twelve inches. Another piece is to be put upon the posts two or three inches below the others, to support the paper shelves. On this plan, it will be perceived, that the hurdles have the appearance of a set of shelves. The whole room is to be thus occupied with the hurdles, leaving alleys between each range for the free passage of the attendants.

The fixtures in the hatching-room, are simply one or more ordinary tables, sufficient to accommodate the eggs to be hatched, a thermometer, and a good stove.

HATCHING.—About the first of May, the eggs, which have, of course, been kept in the cellar since the time they were laid last season, are to be put in the hatching-room; the papers on which they are, are to to be spread out on the tables. If the temperature be not as high as 70°, it must be raised to that point before the eggs are taken to the room; if it be higher, *naturally*, it is of no consequence. Every day the temperature should be increased one or two degrees until the eggs are hatched; unless, as just observed, the temperature be above 70° naturally, in which case all that will be necessary is to prevent a depression at night, and changes of the weather. It will not be necessary, at any time, to raise the heat higher than 80°. Generally, in about five days the worms will begin to hatch. The first day, but few will come out, and these need not be regarded; but on the second day, considerable numbers will hatch, and they should be taken and placed on the hurdles, and the hurdles containing each day's hatching should be marked with the date of the hatching. Where there are four laboratories, as recommended in a previous page, each day's hatchings should be conveyed to separate rooms. On the third, fourth and fifth days of the hatching, the same routine must be observed. On the latter day, all the eggs will be found to have hatched, except a few scattering ones, which, like those of the first day, need not be regarded, as they will be too few in number to be worth any trouble; and if mixed with the others, will only cause confusion by their irregularity in moulting, &c.

For removing the young worms from the hatching-tables to the hurdles, I have found the best method to be, to lay whole mulberry leaves on the table, covering the eggs and worms completely. The young worms will soon collect upon the leaves, when they are readily conveyed to a small portable hurdle, by taking hold of the stem of the leaf, borne to the laboratory and laid upon the hurdles. Many thousands may be accommodated on each hurdle for the first week; and as the worms grow, and become crowded, they must be distributed to other hurdles. All these minute affairs will suggest themselves to the intelligent operator, as they become necessary. The morning is the time for removing them, as they generally hatch from day-light to 7 or 8 o'clock.

As soon as the young worms are placed upon the hurdles, a supply of food must be given them. The leaves may be torn into small pieces, and scattered over the surface of the hurdle, covering the young worms with them. They will speedily commence eating. The leaves on which they were borne from the hatching-room will, however, be sufficient for several hours. The worms are now to be regularly fed three times a day, with fresh leaves, torn into small pieces, the size of a dollar, or thereabouts, for the first week; after which, they are as well laid on whole. Care should be observed, not to lay on more leaves than will be consumed, as considerable waste would thus occur; and, also, not to allow the worms to remain one moment without food; it were far better economy, indeed, to waste leaves by giving too much, than to stint the worms, at any stage of their existence. For the first two weeks, no other care is necessary than attention to their being properly fed three times a day, as above remarked; keeping the room at a moderate temperature, by artificial heat, when cold, and by ventilation, when hot and sultry. The French divide the time of the worms' existence into periods, which are distinguished by their moulting, or shedding their skin. These periods are called ages, and very particular directions are given for observance at each of these periods or ages. I, however, have never found any particular necessity for much variation in treatment. Cleanliness, moderate temperature, and a full supply of food, at all times, are all I ever found either necessary or useful at any time. The periods of moulting are generally about the seventh, thirteenth, nineteenth and twenty-fourth days from the hatching; but these periods are materially influenced by the care and attention bestowed, and the state of the weather. Some worms will be ready to spin on the 25th day, while others will delay their spinning even to 40 and 50 days, according as they are well or illy attended to. And here let me advise the young beginner, that *care is money;* for there is no kind of human employment in which care is so well rewarded, as in the management of silk-worms. The worms that by want of attention are made to spin out their time of feeding to 40 or 50 days, will have consumed double as much food as those that begin to spin their cocoons on the 25th to the 28th day; will have occupied double the time of the attendants; and, after all, will not produce much, if any, over half as much silk, and that of an inferior quality, as they would have done, if well attended to, and thus made to spin at the proper time. This fact, which I have abundantly proved in my own practice, should never be lost sight of.

The French also direct certain quantities of leaves to be given each day, during each age of the worms. This I never found of any service whatever. Worms will eat double as much one day as they will another, owing, probably, to the dampness or dryness of the air, or to various other causes; but whatever the causes be, the *ten* or *twenty pounds* of leaves directed to be given them, may be entirely too much or far two scanty an allowance. My plan is to keep fresh food on the hurdles at all times, and this I believe to be the only economical rule. I have often weighed the leaves according to Count Dandolo's scale, but never found the quantities he recommends to agree with the demands of the worms—they sometimes requiring more, and sometimes less. I imagine, that the idea of weighing the leaves for each day's consumption, in France, originated in the fact, that the leaves are grown by one person and the worms raised by another in that country; the person who raises the worms purchases the leaves by weight, and this making it necessary that the consumer should form some estimate of the probable quantity he would want each day. It could not have originated in practice; for, as before remarked, the consumption of leaves is not regular at any particular time.

The French also direct the leaves to be cut fine, and have knives for the purpose. The Chinese also do the same. For several seasons, I followed these directions, and cut the leaves with a sharp knife, but was ultimately led to doubt the utility of it, and to abandon it. On close observation, I found that the worms did not like the cut edges of the pieces of leaves, and have often seen them turn from them in apparent disgust. I at first supposed my knife was not sharp enough, and that hence the edges of the leaves were somewhat bruised in cutting; but it was the same with the sharpest knife I could use. Besides this, I found that the worms would get upon and press down the finely cut leaves, and thus cause considerable waste; and, further, that the leaves thus cut, would wither and become useless much sooner than whole leaves. On trying even the youngest worms with whole leaves, I found they would eat them just as easily as when they were cut. Even the old full grown leaves were as readily devoured by young worms, as young and tender leaves would be. From these facts I concluded that even if cutting the leaves were never so unobjectionable, it yet was a useless trouble, and I abandoned it altogether. Indeed, when I fed with white mulberry leaves, I even went so far as to gather the leaves by cutting off small branches and laying these on the hurdles with all the leaves on them; and this is by far the best plan, as the leaves keep fresh much longer—indeed, until they are entirely consumed, and allow the worms a much better and more natural position while feeding; as they get upon the branches, in all directions, they are not crowded upon a flat surface, but are supported by the branches. *They* prefer this plan to all others.

Clearing the hurdles must be attended to, not at regular periods, but as often as the accumulation of filth and offal makes it necessary. The use of the net hurdles renders this not so often requisite, but still it must not be neglected, especially in damp weather; for it must be borne in mind, that nearly all the diseases of silk-worms proceed from foul hurdles. To clean the hurdles, all that is necessary is to lay over the worms some large fresh leaves in the morning, and as soon as the worms attach themselves to them, which they will immediately do, take the leaves by the stem, and lay them on a clean hurdle. In a few minutes a hurdle may thus be cleared of the worms, when the filth and offal may be thrown away, and the hurdle used for the reception of the worms from another; proceed in this way till all are cleared. It is a good plan to carry the filth to a distance from the laboratory; as, if deposited, as is too often done, *under the back window,* it may do just as much harm as it would if left on the hurdles.

Fresh leaves are essential to the health and vigor of the worms, and therefore great care must be observed that fermentation has not commenced, when they have been kept on hand some time, as is necessary in wet weather. Fermentation will be readily observed from the effluvium in the room, and also from the appearance of the leaves, which will exhibit dark-colored spots. When the least appearance of it is discovered, it were better to throw away the whole, than run the risk of injuring the worms. To prevent fermentation, cause the leaves to be well stirred about two or three times a day.

Wet leaves, must in no case be given to the worms. They are almost certain to cause disease, and that of the most fatal character. I once lost a whole crop by this means. In wet weather, the leaves may be dried by spreading them about the room, and frequently shaking and stirring them about.

Vermin, mice, ants, &c., must be guarded against. Mice devour silk-worms with wonderful avidity; and the bite of an ant is almost instant death to them. The only way to guard against mice, is to exclude them from the room by some means. Ants may be guarded against by not allowing the hurdles to touch the walls, and by surrounding the legs of the stands with small leaden troughs, filled with water. These are easily formed, and ought not to be neglected when these little pests are troublesome.

The moulting, or changing the skin, takes place generally with the common silkworms, as above stated, and will be observed by the worms ceasing to eat. Generally all of the same day's hatching moult at the same time; and at these times they do not eat, but seem sick. All that is to be done is simply to leave them undisturbed. The food last given them will be left unconsumed, or only partially so. This forms convenient recesses for them to retire to for moulting. They remain in this sickly state from 24 to 36 hours, and their recovery from it will be immediately observed by their activity, and increased size, and considerable change of color. They should be fed immediately with fresh leaves. The first and second change is so imperceptible as to require a close observer to discover them.

Strict attention to cleanliness, and ventilation, and undeviating regard to keeping a full supply of fresh leaves on the hurdles, are all that is meant by me when speaking of *care and attention*. If the above rules be completely carried out, the worms will begin to spin in from 25 to 28 days. If the worms are not thus carefully attended to, they will begin to spin at any time within 60 days, and then their cocoons will be the less valuable for every day their spinning is protracted beyond 30 days from the time of hatching.

THE AIR of the worms must always be kept sweet and pure. If from any cause whatever, a stench be observed, sprinkle the floor with a solution of chloride of lime, and set cups of it about the room. It is a good plan always to keep a stone jar of it sitting in one corner of the room, and frequently changing it to different places, even when no foul air or disease is present; for it is always better to prevent than to wait to cure diseases. All the diseases I ever discovered in silk-worms are readily cured by the free use of chloride of lime or soda. The *tripes* is a disease induced by foul air, and is closely analogous to the plague in the human species. I have known it to destroy a whole laboratory of worms, consisting of about 500,000, in one night; and have myself lost at one time about 100,000. Since, however, I discovered the preventive and curative powers of this most excellent article, I have never lost a worm by any disease. All that is necessary, usually, is to keep the chloride of lime in the room, as above stated, and occasionally sprinkling the floor with a solution of it. A table spoonful, put into a pint of water, is a good quantity to use. If, however, the disease has commenced its ravages, lose no time in removing the hurdles containing the diseased worms, from the room—then take half a pound or so of the chloride, put it into a gallon of water, sprinkle the floor well with it; put a spoonful of the chloride in each of several saucers, with a gill of water, and set the saucers about the room, particularly where the disease was first observed. As these diseases always, or at least generally, appear in damp, cloudy, or rainy weather, make a brisk blaze in the fire-places or stoves. Throw open all the windows and ventilators; and take care that all the filth, if any there be, be removed. In a few hours you will find the disease checked. If there are any dead worms on any of the hurdles, they must be removed forthwith.

Here I must be indulged with an explanation of a circumstance of a rather laughable nature, though it is as much at my own expense, as any body's else. It is in relation to the discovery of the valuable properties of chloride of lime, in preventing and curing disease in silk-worms. It is well known, that I have often claimed the *discovery* of this most valuable agent, and that some years ago a scientific *Frenchman* read a paper before a learned society in Paris, setting forth the important fact of its then recent discovery, and elucidating its great value to the silk growing interest. What will the public think of me, and of the Frenchman of science, and especially of the learned society of Paris, when informed, that we are NONE OF US entitled to the credit of discovery; that it is an old remedy—an old agent, used and recommended by Count Dandolo himself, whose writings we all of us had read, whose writings were and had long been familiar as household words to the savans of Paris! Yet, such is the fact, though I never was aware of it until this present writing, when I discovered it while looking over a translation of the writings of Dandolo in the Silk Manual, published by order of Congress, in 1828, in which work it will be found at page 119. The article chloride, it is true, is not mentioned by Dandolo at all, but its elementary principles are described and recommended, for the purifying of noxious air, very distinctly. I had often read the passage, and understood something of chemistry too, but never suspected that the combination of a portion from Dandolo's bottle of common salt and black oxide of manganese, and another of sulphuric acid, would produce chlorine gas. It is true, had I reflected a moment, I should have discovered it; but all of us are in the habit of considering things *themselves*, not the individual materials of which they are made. Hence my oversight, and of course that of the learned men of Paris. For my own part, I ask pardon of Dandolo for the claim I have heretofore set up to his property; but would recommend him to be a little more explicit in future, in his descriptions. But the fumigation of Dandolo, though it be chlorine gas, is not as good as the chloride of lime or of soda; as the gas evolved is not pure, but contains large portions of deleterious gases which are necessarily evolved with the chlorine. Besides the chlorides of lime and soda are infinitely more convenient, and even cheaper.

It seems necessary to recur to the *temperature* of the room, for the purpose of noticing an omission while treating on that head. In very high temperatures, the French recommend sprinkling the room with cold water, for the purpose of cooling it. I have often done injury by doing so, and recommend that it be not resorted to. It of course creates a dampness in the air, which is injurious and often dangerous. If the weather be dry, free ventilation is all that is necessary, where proper cleanliness is observed, let the weather be never so hot. Darkening the room, has a good effect in hot weather; and at no time must the sun be allowed to shine upon the worms. A *twilight* is preferred by the worms.

The worms will begin to spin cocoons from the 25th to the 35th days from the hatching, depending on the care with which they have been attended to. As before observed, if carelessly attended to, they may not begin before the 40th or 50th day; but generally the 35th day will be the time of commencement. Their readiness to spin will be immediately observed by their transparent, slightly amber color, by their ceasing to eat, and wandering about, leaving fibres of silk on the leaves, and by some of them actually beginning to spin cocoons among the leaves and rubbish on the hurdles, in the corners of the frames, &c. It is then necessary to prepare the *hedges* for them to spin on, or such other contrivance for the purpose as has been determined on.

The hedges for the worms to spin their cocoons on are composed of various materials, and are as various in form. The French and Italians use brush of oak and various other kinds of trees, from which they construct hedges across the hurdles, resembling miniature bushes set close together in rows, and pressing against the hurdle alone. The worms climb these hedges, and spin their cocoons among the branches. I always used *broom-corn*, and found it to answer admirably. The seed is carefully to be combed off, the stalk cut off close to the commencement of the straw or brush; the top cut off square, and spread out, pressing against the upper hurdle or paper shelf, and the lower end resting upon the netting of the hurdle. Rooms of these set across the hurdles, six or eight inches apart, and as close together in the row as the tops will admit, answered the purpose with me. Of late, however, cocoon frames, made of laths, have been used, and with success, by many persons. I have never seen them, and am unable to give such a description of them as will enable the reader to construct them. Various other contrivances have been adopted, entirely different from either of the above, and even from each other; and, their authors assert, equally effectual for the purpose. These facts only prove that the silk-worms are not very particular as to where or on what they form their cocoons. They will, indeed, spin them any where; the only object to be attained by particular structures for them to spin on, is the prevention of waste of silk matter in forming the *outlines* of the cocoon. Where there is a space just large enough for the cocoon, very little silk will be wasted in the form of tow, or refuse silk. If the space be too large, the worm is compelled to reduce it, by filling it with loose fibres, to the proper dimensions for the cocoon.

As the worms on each hurdle begin to spin, the hedges, or whatever else is to be used, must be supplied; and the attendants should keep an eye upon the worms, to see that they all spin in the proper places. Some will not rise to the hedges or other places prepared for them, but commence spinning on the leaves in the corners of the hurdles, &c., they must be taken and placed upon the proper place. Observe that they do not get crowded too close in the hedges or other places, so that they will not each have room for a cocoon; for if they do, they will form *double cocoons*—that is, two or more will join in forming one cocoon, which is good for nothing, except for carding and spinning, as it cannot be reeled.

The worm is four days spinning its cocoon. Consequently they should be left perfectly undisturbed during four entire days after they commence spinning. On the fifth day after the whole have commenced, the hedges or other support of the cocoons may be taken down, and the cocoons taken off. Select the number of cocoons you may want for the production of eggs for next year, and prepare the others for reeling or for sale. If you can do so, the best way is to reel them at once; if not, the insect must be killed.

Various methods of killing the insect are in use. In France they bake the cocoons in an oven from which the batch of bread has just been drawn, or which has been heated for the purpose to about 150°. If too hot, the silk will be scorched, and thus ruined; if too cool, the insect will not be killed. In Italy they effect the object by exposing the cocoons to the hot sun for several days. Others kill them by filling a vessel containing them with hot steam; others with vapor of spirits. I have lately suggested that they may be effectually killed by the vapor of charcoal—carbonic acid gas—and for this purpose they may be carried into the *hatching room;* all the doors, and windows, and chimney of which must be perfectly closed. Dispose the cocoons about the room on the net hurdles, one above another, similar to the hurdles in the laboratory. Fill a common portable furnace with charcoal, and set it on fire; place it in the middle of the room, and close the room perfectly. In a short time the room will be completely filled with the deleterious gas, and must of necessity smother the chrysalis in the cocoons. I have heard of this plan having been tried in one instance only; but, in that, it was perfectly successful, and I have no doubt it will always be so. If it is, it is an important improvement, not only in saving much labor and time, as well as expense, in this part of the business, but in saving a great deal of trouble in reeling the cocoons, as it does not harden the gum, as all other processes do, and consequently they are easier to reel. Besides, there is no danger of injury to the silk, which is always more or less depreciated in value by the heat applied in killing the chrysalis. I am at present clearly of the opinion that this process will be universally adopted; but I have only *theory*, and one experiment, for the basis of this opinion. I am not now engaged in the business, and have no opportunity to make the necessary experiments. I would advise that a few cocoons be at first tried, say two or three pounds; that the cocoons thus tried should then be spread out in a warm airy room, for at least two weeks; if none of the *insects* come out, the result will be conclusive. The cocoons are now ready for reeling, or for sale.

Eggs for the next year's use are to be obtained as follows. Spread out the cocoons selected for the purpose on a large table, in any room that can be kept warm and comfortable, and that can be made dark. In about ten days from the time the cocoons were finished, the *moths*, or butterflies, as they are sometimes called, will perforate the cocoons, and come out. They will immediately couple, and are then to be taken in pairs, and placed upon the paper suspended for their accommodation, as described in the following paragraph.

Stretch a small cord across the room, about as high as your head, then two others, two and a-half feet apart, and one foot below the first cord, so that the first will be over the centre, between the lower ones. Then hang old newspapers over the cords, and pin them to both top and bottom cords. This will form a long range of papers, resembling the roofs of a long row of houses. As the moths couple, place them on these papers; take them by the wings between the thumb and fingers, as they will not be separated by it. You need not trouble them further; as after they separate, the female will commence laying eggs, and attaching them to the paper in a small spot about as large as a cent. Put moths enough on each paper to cover the whole sheet with eggs; but not so many as to compel them to lay their eggs on those already there, that is, to pile the eggs on top of each other. This they never do unless from necessity. After they have done laying eggs, the moths generally die in a day or two; the males generally die soon after they separate. The moths do not eat. The recommendation of the French, to separate the moths after they have been coupled *six hours*, is perfect nonsense, and is one of the ridiculous refinements that refined people have tried to apply to the silk-culture, without the shadow of utility to recommend them, and only remarkable for the great additional labour and perplexity with which they encumber the business. Like all the other fooleries of the French, I tried this, and got for my pains no other result than a loss of about one-third of my eggs, which were *not fecundated*, as I might have expected. Let the moths remain together till they separate of themselves, and all your eggs will be good. The room where the cocoons and moths are should be kept nearly dark.

As soon as a sheet is filled with eggs, take it down, roll it up, and put it away in a cellar or an *ice-house*. They should be put in a *tin* or other metal box, to prevent mice and other vermin from eating them, and should be kept dry, to prevent mould and mildew. If it be desired to keep eggs to a late season the next summer, for the purpose of raising several crops, it is best to put the box of eggs, immediately after they are laid, into an ice-house, and keep them there till wanted. If they are only kept in a cellar till the next spring, and then put into the ice-house, they will hatch in the ice-house very nearly as soon as those exposed for hatching in a warm room. I once had more than a million hatched in this way, in the largest ice-house in Baltimore, the basket containing them sitting in the midst of the blocks of ice, under the straw. I do not even know that putting them in the ice-house immediately after they are laid, will prevent their hatching, but am informed that this has been the effect in several instances where it has been tried. For myself, I have no faith in the double or treble crop theory. I do not believe it will ever be profitably pursued. The natural time of hatching the eggs cannot in my opinion be either anticipated or postponed with complete success—at least I never was able to do so.

To estimate the number of cocoons you will want for a given number of eggs, all you have to do is to divide the number you want by 150—thus, if you want 100,000 eggs next year, or 2½ ounces, divide 100,000 by 150 and you have 667 as the number of cocoons required. It is true, the moths often lay more than 300 eggs, but you must allow for various circumstances that may diminish the number. I need not remark that it requires *two cocoons*, a male and female, to produce the 300 eggs—however, we allow 150 to each.

This essay may not be considered as full and minute in its details as desirable by some; but I believe I have described every thing necessary to the most profitable carrying on of the business. Many particulars contained in books, especially French books, are not noticed at all, for the simple reason, that I deem them useless, and do not wish to occupy the reader's time in useless criticisms. My next number will treat of the *reeling* of cocoons, &c., which will complete the series.

PROTECTION AGAINST HAIL-STORMS.

By A. J. Downing.

The *paragrele*, or hail-rod, appears to be scarcely known at present in this country. Hail-storms are undoubtedly much less frequent here than in the middle and south of Europe; but, nevertheless, some districts of the United States seem peculiarly liable to hail-storms in summer, and an account of the means at present in use on the continent of Europe to guard against such evils will be acceptable to many of the readers of this Magizine.

The paragrele, we believe, was first invented by M. Lapostolle, of Amiens. It has, however, been considerably improved by Professor Trollard, of Tarbes, whom we quote for authority for the following description from Berneaud's excellent *Manuel du Vigneron.*

"To make the hail-rod, a rope of straw is the first thing necessary; it must be made of ripe wheat straw, soaked and twisted, plaited with three strand and then with four ply, making twelve strand to the rope. This cable of straw must be twenty-five feet long, and through the centre there must run a strong twine of tow yarn: this cable of straw must be fastened at top and bottom to a stake of the same length, solidly fixed in the ground, and armed at the top with a metallic point of tin, *(latten,) with no iron.* The stake should be a pole of firm wood, entirely cleared of bark, which makes it liable to rot. The cable is fastened, at each end, by a wire of tin, or, what is better, red copper, and must be stretched tight, and tied to the pole, at intervals of every foot and a half, with the same wire. The tin point at the top should be one and a half inch thick and eight inches long, placed in direct contact with the tow yarn. The hail rods should be about six hundred feet apart, and fixed upon the most elevated points, such as the tops of hills, roofs of houses, or trunks of stout trees. The cost is about a franc a piece, (twenty cents,) and they last at least fifteen years."

These hail-rods, so simple in their construction, and easily obtained in every part of the country, have now, we believe, been in use nearly twenty years in France and Switzerland. Many extensive districts in both these countries, which formerly suffered severely from hail-storms, and in which the crops and vineyards were subject almost annually to great destruction, are, since the paragrele has been generally adopted, protected almost entirely against their desolating effects. The Linnæan Society of Paris, some time since, with a commendable zeal, made extensive inquiries in all parts of the continent respecting the utility of this instrument, and the result, as exhibited by them, proves the paragrele, in all districts liable to hail-storms, to be an invention truly invaluable. Public experiments were made in such parts of the country as were most subject to hail-showers, and while those districts where paragreles had been erected were quite protected, neighboring districts not guarded by these hail-rods, were, as before, much devastated. The society, drawing their conclusions from the facts elicited by the various trials made in France, estimated that the annual saving which would arise from the general adoption of the paragrele, throughout that country, would not be less than five millions of dollars.

Considerable difference of opinion exists as to the method by which the paragrele produces its effects. A commonly received theory, based on the supposition that hail is produced by a congelation of the drops of water, in very elevated strata of the atmosphere, is, that the hail-rod, by attracting and detaining these vapors in a lower stratum than that in which freezing takes place, prevents its formation. But as hail-storms are generally accompanied by thunder and lightning, an American writer has suggested that the paragrele acts by abstracting the superabundance of electricity from highly charged clouds. The formation of hail, according to this writer, takes place only when, by the sudden passage of the electric fluid through the cloud, a portion of the water is decomposed, and returns into its original gaseous state, the heat abstracted (by the change from a liquid to an aeriform state,) from the neighboring particles (or clouds?) is so great as to convert them into ice, when they descend in the form of hail. The decomposition of a single cubic inch of water, according to the tables of *Biot*, will reduce the temperature of 5,64 pounds of water from 72 degs. to 32 degs., the freezing point of Fahrenheit. The decomposition of water by the electric spark is now a well known fact, but the peculiar manner in which electricity acts upon the clouds, or the exact manner in which they must be situated, in order that hail shall be produced, does not yet appear to us to be clearly demonstrated. That, however, the electric fluid is a necessary agent in the production of hail in summer, we can scarcely doubt; and the claims of the paragrele or hail-rod appear so well established, that we do not hesitate to recommend strongly the use of so valuable a means of protection in all parts of the Union liable to frequent or destructive hail storms.

Newburgh, N. Y., July 15, 1837.

From the Farmer and Gardener.

SMITH'S LIME-SPREADER.

We have before noticed the invention of a machine for spreading lime, by our ingenious fellow-citizen, *Francis H. Smith*, Esq., and revert to it again in consequence of the repeated applications that have, of late, been made to us for information as to its efficiency and cost. To speak then, first, of its efficiency. There is no doubt in our mind, and we believe there is none in the mind of any person who has seen it in operation, but that it is a most useful machine—one that is eminently calculated to promote the object for which it is intended, and that it not only economises time, but does the work better than it can possibly be done by hand.

One of the most desirable things aimed at in liming, is the *equal distribution* of the mineral over every part of the field, and this, it must be admitted by all candid persons, cannot be effected by shovel-spreading, as with all the care and precaution that may be taken, inequality will ensue in despite of the best directed efforts.

Again, it is almost impossible, by such spreading, to *regulate the quantity* sown on the acre, and hence disappointments often occur to the mortification and cost of farmers.

The injurious effects, too, of the old method of spreading, upon the lungs and eyes of those engaged in such work, have always been subjects of regret, if they have not restricted the use of this generous agent in the fertilization of the soil.

We are happy to say, that one and all of these objections have been completely obviated by Mr. Smith's machine, and that by it the following results are produced.

1. Owing to the beautiful and nice mathematical arrangement of the several parts of this machine, it is perfectly practicable to distribute any given quantity of lime evenly and equally over every part of the field; such is the equality of the operation that the ground after the work is done is covered with as much nicety as if the distribution had been effected by patient laborers from hand-sieves.

2. By the substitution of different cog-wheels, the machine may be so regulated as to spread 50, 75, 100 or 150 bushels of lime upon the acre, as may best suit the views of the farmer; and any of these quantities may be distributed with the greatest nicety and exactitude.

3. From the peculiar construction of the machinery, no disagreeable effects result to the workmen while engaged in their labor, as but little dust arises, and that which does, is left behind by the cart, so that the laborers are not at all incommoded thereby.

The above advantages we have pointed out, will, we are sure, be considered as important *desiderata* by all intelligent farmers; but independent of these, there is another of great moment. We allude to the superior despatch with which the work can be done. Two hands with a cart and horse, can spread *an acre* an hour, with perfect ease.

The reader, we hope, will be able to comprehend the principle and construction of the *spreader* on perusing the following description.

It is a neatly made *cart*, adapted to either one or two horses. In the bottom of it, about a foot in the rear of the axle, a hopper is formed, within which two rollers, reaching from side to side, revolve by means of cog-gearing, moved by a cog-wheel located upon one of the hubs. The rollers are made of iron, one of which is fluted to the depth of about three-fourths of an inch; the other is smooth, one of these rollers is borne upwards by a spring, which is of great strength, but which is so constructed as to give way, or recede back whenever a stone too hard to be crushed presents itself for passage between the rollers. This is an object of great value, as it not only provides against a stoppage of the machinery, and consequently saves time, but preserves the machinery itself from injury.

The machinery is *simple;* easily kept in order, and may be repaired by any common country *smith.*

It is calculated for spreading *lime*, either dry or wet, (stone or shell,) *ashes*, *marl*, or *ground bones*.

When not used as a *lime-spreader*, by fitting in a slide, which also accompanies the cart, it may be used for all other farm or market purposes.

The *price* of the cart, together with its machinery, including the two cylinders for *dry* and *wet* lime, is $110, a sum which should not be considered an object with any agriculturist who has a farm of a hundred acres or more to *lime*, as it would pay for itself in a single season in the saving of labor, besides doing the work infinitely better than in the old way.

From the Mining Journal.

ANTI-DRY-ROT PROCESS.

The advantage arising from the application of Kyan's process for the preservation of timber, has been so generally acknowledged, and has been so well tested by experience, that its general introduction in the mining districts, is one of the natural consequences attendant on its success. It is now some months since it was first introduced in Cornwall, where its use is becoming very general; indeed, when the expense of timbering, shafts, and other uses to which timber is applied in mines, and the heavy cost attendant on works of this nature is considered, its importance must be apparent. In rail-way undertakings it is also adopted; and we learn with much satisfaction, that Earl Fitzwilliam has also ordered its use in the mines possessed by his lordship. This additional evidence of the estimation in which it is held, will, we feel assured, be hailed with satisfaction by all who take an interest in scientific discoveries like the present, and which, in the onset, had so much to contend with, not only from popular prejudice, but from the necessity of testing it by some years' experience.

From the Southern Telegraph.

MEXICO-EGYPTIAN COTTON.

A few days since we accidentally saw a very small quantity of the Mexico-Egyptian cotton, produced the present season on the plantation of the late Dr. Nutt, near this place. We were much pleased with the evident superiority of the article, and solicited* an account of the experiments by which this superiority was obtained. We are happy that our solicitations have elicited the very interesting letter which follows, and to which we invite the attention of our readers—especially that portion of them who are engaged in the production of our great staple. We have in our office, some specimens of this new article of cotton, which we will take great pleasure in showing to all who feel sufficient interest or curiosity to call upon us; and we hope there will be many such.

Messrs. Editors: You requested me to give you the result of an experiment instituted by the late Dr. Nutt, with the view of improving the growth of our cotton, by crossing it with that of Egypt. I cannot, as yet, give you the result, as the experiment cannot be fully carried out, until we have gathered the *small crop* of Egyptian cotton planted last spring; after which I may be able to show you what amount *per* acre it will produce, and to note particularly the relative advantages to be expected from the Mexican and Egyptian cotton. So far the experiment can only prove interesting to the curious. When we are more fully convinced of its usefulness, I will then inform you of the further progress of the investigation.

I learned from Dr. Nutt, that the cotton of the *Nile* seldom grows higher than *three feet*, that the bowls are small, and have only *three compartments*, containing as many *locks* of cotton. The Mexican cotton, as it grows with us, differs in each of these particulars. The stalk grows much higher; the bowls are larger, and usually have *five compartments*.

That these two *varieties* of cotton do cross when approximated, admits of no doubt when we have examined the *new product*, which is an amalgation of qualities peculiar to the Egyptian and Mexican, yet differing from both.

The seed Dr. Nutt brought from Egypt, was planted in a line contiguous to the Mexican cotton; the seed procured from these stalks were planted the following year, from which was obtained seed enough for something like an acre of ground—the subject of our present remarks.

This cotton was planted on the 14th of April, three weeks after the usual time. The consequence of this is, that it is still growing, and but very few bowls as yet have opened; and although the cotton on this place, as well as in the neighborhood, has suffered serious injury by the shedding of *forms* and *bowls*, yet this looks healthy and is weighed down by its rich burden.

The *Mexico-Egyptian cotton* as it now appears, has two or more stalks, measuring in circumference from eight to ten inches. These stalks have innumerable branches, which are larger than the stalks of common cotton growing in like situations. The stalks of each plant attain a common height, say from six to twelve feet. The branches grow erect, and these have arms that extend three or four feet horizontally; at every joint there is a blossom, square or bowl. Mr. H. Nutt had the curiosity to count them last summer. He found upon a single plant, *five hundred*. There is a plant now near the house, which, if any one had the patience to count, may be found as many *well-formed bowls*. The peculiarity of its blossom, is worthy of notice, which is a beautiful bright buff-color. The bowls have but *four compartments*, a feature given it by a compromise between its progenitors. The fibre of this cotton, (a sample of which I send you,) it will be readily seen, is *longer*, possessing *greater strength*—the color, *Mariet*, less bleached, approaching somewhat the much desired "cream-color," and that its texture is finer than the Mexican. This sample, you will mark too, was picked from a few bowls, the first to open, and that the seed were torn out by the fingers. You can conceive how much more beautiful it will appear when its second picking is ginned.

It is a fact, well attested by naturalists, that subjects of the *vegetable*, as well as the *animal kingdom*, when made to procreate from their respective species or families, degenerate. In a few years, the Mexican cotton of the Gulf Hills, which has so long occupied such enviable pre-eminence, may lose that proud title, and become as inferior as the *black seed* that preceded the introduction of the Mexican. Another fact may suggest to the planter the necessity of making some attempt to improve the culture of cotton in *the Hills*. You know, gentlemen, that land, which for a series of years, has produced a certain grain or crop, will become *tired*, and refuse at last to *bear* that crop any longer; that by changing the crop or alternating it with another, thus *resting* it in some degree, that its capability to produce will again be

* Dr. New.

restored. Now, there is no concealing the fact, that much of the land in *the Hills* is impoverished, and some entirely exhausted, and that, unless something is done to restore its productiveness, it will fail to bring good cotton before long, and at last fail to bring any cotton at all.

It was to remedy these evils, to wit: to prevent the degeneration of the Mexican cotton, and to arrest the exhaustion of the soil, that this attempt to cross the cotton has been made; and if the experiment of the Mexico-Egyptian cotton succeeds, we shall have the novel spectacle of worn out lands, *resting*, and, at the same time, *producing* finer cotton and larger crops than at present.

I sat down, to notice simply the peculiarities of this *mongrel cotton ;* but your inquiries have elicited an extension of my remarks, which probably should have been reserved till better warranted by facts, or till my time should have given me leisure to render this communication more satisfactory. But as your curiosity *is to blame* for this hasty account of an interesting operation of nature, you must be satisfied with this statement till the future has developed the result of these speculations. Yours, respectfully,

C. B. New.

Laurel Hill, Sept. 5, 1838.

SUPERIOR PRODUCT OF THE TWIN CORN.

To the Editor of the Farmers' Register.

Old Point Comfort, Oct. 15, 1838.

Any thing connected with the mooted question of the prolific qualities of the Baden or twin corn, must be interesting to your agricultural readers. I will not undertake to settle the controversy; every one should be his own judge from his own experience; but, unless something unexpected occurs to change my opinion, I shall hereafter plant the twin corn, to the exclusion of all other varieties: this determination, is the result of a full and satisfactory experiment.

I planted, three years ago, a field of twin corn, adjoining one of our ordinary large white kind. The product, unfortunately, was not accurately determined, but I was satisfied, that it was greater than the latter. The overseer and negroes, however, condemned it, and I was compelled to relinquish its cultivation. I determined this year to give it another and a fairer experiment, and planted with it a lot of three acres, that was last year in our common corn, and yielded twenty-four barrels. The product this year was thirty-seven barrels of twin corn, upwards of 50 per cent. more than the yield of the previous year. The lot had received no manure, and, as it is fair to presume that it had lost a portion of its productive property by the previous crop, the advantage of soil was decidedly in favor of the first crop. The corn was planted both years alike, in rows five feet wide, and about one and a half feet in the step, and received, as nearly as could be, the same amount of cultivation. As one valuable property of the twin corn is to mature early, it suffered very little from the drought.

From the above facts, let every one draw his own conclusion. Mine is, that on rich land, there is no variety, that we know of, as productive as the twin corn.

Whilst I am writing, I will call your attention to an important typographical error in my communication of last month. Instead of "*several bushels,*" read "*seven barrels.*"*

R. Archer.

THE VERY LATEST AGRICULTURAL HUMBUG, ANNOUNCED IN THE VERY BEST MANNER.

From the N. Y. Commercial Advertiser.

Important to Farmers.—I think, Messrs. Printers, that we have had enough in all conscience of puffing and blowing about family Ravels, *Tree* play actors, men singers, and women singers, Italian fiddlers, and rope dancers, live elephants and monkeys. (By-the-by it is a very prevalent opinion at Cow Bay, Cow Neck, Oyster Bay and Hallet's Cove, that if all those drones were turned out to fell trees, grub up brush and hoe corn, we would not need to import peas-meal and rye-flour from Germany—things which feed the sense of sight only.) Now we, some of your clod-hopping subscribers, think ourselves entitled to half a column of your paper to speak of things which feed the taste, and give nourishment to the body corporate.

Mr. Jefferson says the man who makes three blades of grass grow where only one grew before, is more the friend of man than he who conquers kingdoms. I think if Mr. J. had always preached such sound doctrine, he would have been the greatest philosopher of the age. Seeing, then, that this proposition about the grass is self-evident fact, what think you should be done to the man who makes three ears of corn grow where only one grew before? inasmuch as grass feeds the horse, and corn the man. But to come to the point at once:

Some three years ago a merchant in New York, while emptying a box of tea, observed therein a few grains of corn. Concluding that corn from China must be something new under our sun, he had them planted, so they grew and multiplied. Last spring, I received from a worthy friend, a portion of said corn—it's a new variety—so I gave it the name of China's fall prolific, or tree corn; as it strikes off in two, three, and frequently four branches, in appearance like a small tree, and produces an ear at the head of each branch, whereas the common corn shoots out the ear from the side of the stalk; it grows from eight to ten feet high, produces an abundance of fodder, and is a large white flint twelve rows long, and ears from ten to fourteen inches long. I counted six hundred and sixty grains on the ear; it was planted on the 10th of May, and had ears fit to boil on the 10th of July. Its produce was curtailed by the long drought, but notwithstanding I counted two thousand one hundred and twenty grains, the product of one stalk: being an increase of two thousand and one. The Dutton (which is an excellent corn) planted on the same day, on the same field, and received the same quantity of manure, cross ploughed and hoeing, did not produce one half. The patch about two hundred hills,

---

*This was indeed an important error, and which our readers are requested to correct in their copies.—Ed was examined by many respectable farmers, who all pronounced it something new, and something superior.

The corn may be had of G. C. Thorburn, New York, and at the store of Wm. Thorburn of Albany, price 25 cents per ear; the net profits to be given to some of the charitable institutions in New York and Albany. Now, if there is a farmer between Maine and the Rocky Mountains who would rather pay 25 cents for two gills of brandy, than to buy one ear of this corn, which will plant 100 hills—I say, if there is a man, he ought to be fed on nothing but supaun and buttermilk as long as his little soul and big carcass will hang together. A stalk, having the ears on, to show the manner of growth, may be seen at the above stores.

☞ Every printer in Kings, Queens, Dutchess, Orange, and Albany counties, who is fond of *Jennie cake*—(for if my informant speaks true, it took its name from a Southern lass by the name of Jennie Dawson, who was famous for manufacturing this delicious article; but that at a meeting of the Bachelor's Club, Jennie was voted out and Johnny put in her place—I only hope that some of those chaps who were concerned in an affair so ungallant, may never taste one of those new made cakes, when well anointed with fresh butter)—will please insert as much of this long winded story as they see fit; and every printer who has children, who ere long may be orphans, will please insert the whole, and place it to the credit of the widow and the fatherless—he who is their Judge will register the thing in Heaven, as Uncle Toby says.

GRANT THORBURN.

Hallet's Cove, Sept. 24, 1838.

We take the earliest opportunity which the time of our publication offers, to give additional circulation to the foregoing communication; and to award to it our praise of its being the most admirable, as well as the newest specimen which we have met with, among the annunciations and puffs of agricultural humbugs. Readers, of almost every description, are like to be induced to read the article, by some one of its attractive points. First, the general heading, of "important to farmers," though so often falsely and foolishly used, is very sure to attract, at least, a cursory glance from every one of the profession; and then the attention will be held by the little matter of narrative—by the slip-shod and familiar gossiping manner of the writer—the novelty of the article described—and confidence in the truth and disinterestedness of the writer will be fixed, and the reader entirely captivated, by the noble offer of giving the profits, (*net profits*, mark you,) to some charitable institution. Now, on this point, we will merely observe, *en passant*, that if the charges of all expenses of agency, commissions, &c., &c., &c., such as are often made, and may be made without question in this case, do not serve to give the lion's share of the profits to the salesman, and benevolent discoverer of the merits, of the Chinese corn, then he understands less of his business than we give him credit for.

But with all the merit of Mr. Thorburn's laudatory annunciation, we must say, that in one particular it is very deficient—astonishingly so, when it is considered that Mr. Thorburn is so old and well experienced in his business. He has certainly lost the chance of increasing his purchasers ten-fold in number, and his profits, (gross and perhaps "net" also,) by his charging so low a price as 25 cents per ear for his corn. According to all the rules of humbug, he ought to have charged 25 cents *per grain;* and the eagerness of purchasers would have been increased in the ratio of the difference of price. On the contrary, if he had asked only $1 the bushel, or offered to give away single ears, very few persons would care to try the planting.

So much for the annunciation. Of the corn itself, it may, or it may not, be a good kind. It would be as presumptuous in us, upon this statement, to pronounce it of no greater value than the ordinary kinds, as it is in Mr. Thorburn to assume so much value for it, upon his few facts, and very slight experience of its growth. We merely *believe* that it is of no superior value to other kinds, except, like spring wheat, as a humbug; but do not pretend to *know* it. But we deny that the product of 2120 grains from the several ears of a single stalk, on garden culture, is any proof of its superiority, or great value, as a field crop. Such a product of particular stalks on rich land, is not very rare here, and probably of grains larger than the "Chinese." Of a particular kind, called the "Georgia gourd-seed corn," we have heard of, (and believe we have counted, some twenty years ago,) more than 2,000 grains upon a single ear; and for aught that we know, the stalk might have borne more than one ear. At least we know that some ears had as many as thirty-six rows; and the largest, when just ripe, would yield very nearly a quart of grains. This kind of corn united several of the requisites considered so important by fancy-variety-corn-culturists. The ears, when well made, were not only enormously large, and the number of rows and of grains very great, but the grains were very deep (or long) and the cob very large, so as to hold so great a number of grains. We remember well the delight with which we received a few ears of this mammoth corn, and the care with which it was planted, by single grains, and at wide distance, on the richest spot of a good field. Yet the returns, tried for two years, proved that it was very unproductive (for this climate) in measure; and, in all respects, it was the worst kind of southern corn we had ever tried. Yet what a glorious subject would this very corn furnish for a successful humbug, in such good hands as those of Mr. Grant Thorburn!

We see that the editors of newspapers are already helping Mr. Thorburn handsomely in his appeal for the widow and orphan, by re-publishing his letter. The editor of the 'Sun,' however, out-strips all his brethren, and even Mr. Thorburn himself, in commendation. He closes an account of the letter and its subject, with the following sentence. "It is considered as much superior to our corn, *as the morus multicaulis, or Chinese mulberry, is to that of the American tree.*" Aha! Mr. Thorburn! "*Chinese* corn" was a lucky name, and its application highly creditable to your judgment. There is now a fascinating power in the word "Chinese;" and there is no knowing how large a "Chinese corn" bubble might be blown, before its bursting at next gathering season, but for the committing the grand blunder of not charging 25 cents a grain for the seed!

From Brewster's Journal, 1830.

VILLAGE LIGHTED BY NATURAL GAS.

The village of Fredonia, in the western part of the state of New York, presents this singular phenomenon. I was detained there a day in October of last year, and had an opportunity of examining it at leisure. The village is forty miles from Buffalo, and about two from Lake Erie; a small but rapid stream, called the Canadoway passes through it, and after turning several mills discharges itself into the lake below; near the mouth is a small harbor with a light-house. While removing an old mill which stood partly over this stream in Fredonia, three years since, some bubbles were observed to break frequently from the water, and on trial were found to be inflammable. A company was formed, and a hole an inch and a-half in diameter, being bored through the rock, a soft fetid limestone, the gas left its natural channel and ascended through this. A gasometer was then constructed, with a small house for its protection, and pipes being laid, the gas is conveyed through the whole village. One hundred lights are fed from it more or less, at an expense of one dollar and a-half yearly for each. The flame is large, but not so strong or brilliant as that from gas in our cities; it is, however, in high favor with the inhabitants. The gasometer, I found on measurement, collected eighty-eight cubic feet in twelve hours during the day; but the man who has charge of it told me that more might be procured with a larger apparatus. About a mile from the village, and in the same stream, it comes up in quantities four or five times as great. The contractor for the light-house purchased the right to it, and laid pipes to the lake; but found it impossible to make it descend, the difference in elevation being very great. It preferred its own natural channels, and bubbled up beyond the reach of his gasometer. The gas is carburetted hydrogen, and is supposed to come from beds of bituminous coal; the only rock visible, however, here, and to a great extent on both sides along the southern shore of the lake, is fetid limestone.

From the London Farmer's Magazine, August, 1838.

WHAT QUANTITY OF MANURE SHOULD BE APPLIED TO THE ACRE?

The answer to this question involves many considerations which preclude a definitive reply, such as the condition of the land, the quality of the manure, and the kind of crop. Too much, as well as too little manure may be applied. What would be beneficial for an autumn-ripening, or hoed crop, would be prejudicial to a small grain, or summer-ripening crop, and more particularly if the manure is applied in an unfermented state, and be withal a waste of fertilizing matter. Twenty tons to the acre would not be too much for corn, potatoes, ruta baga, &c., if applied broadcast, and plouged in; but, if long manure, and applied in the drill, or hill, and a dry season should ensue, it might prove an injury; and if this quantity of long, or even short manure, were applied to the acre of small spring grain, it would probably cause a flush of straw, likely to be affected with rust, at the expense of the more valuable part—the grain. Dr. Coventry, late professor of agriculture in the University of Edinburgh, whose business and study it was to collect data, and make correct deductions in this and other agricultural matters, was of the opinion, that from four to five tons are yearly requisite to keep up the fertility of a soil of the kind usually denominated spit, or tolerably rotted dug; and this supply he thinks a well managed farm may be made to produce. To show how this quantity may be obtained, and how it should be applied, we quote from Mr. Youatt, the writer of British Husbandry.

"According to that calculation," says our author, "it must be observed, that the course of crops is supposed to consist—on light soils, of the alternate plan of corn and green crops, (see New System of Husbandry,)—on clays which do not admit of that system, that the holding contain a proportionate quantity of grass land; and that the quantity of manure should be supplied not in small quantities annually, but in large ones, at intermediate distances of four, five and six years. Light soils, in the common course of husbandry, rarely require the application of putrescent manure oftener than once in four years, and in all cases where the clover is allowed to stand two seasons, it may be deferred without disadvantage for another year. Heavy soils may run six years without it, provided that the land be laid one year in fallow, and that there be sufficient meadow to be reckoned at least one crop in the course. It being, however, clearly understood, that—whether on light or heavy land—nothing but grain, seed and live stock is to be sold off the farm, unless replaced with an equal portion of purchased dung; that the whole of the green crops; the haum of pulse, and the straw of corn, be used in the most economical manner; and that some of the live stock be either soiled or fattened upon oilcake, which plan, if carefully pursued on good soils, with capital sufficient to secure an abundant working and fattening stock of cattle, ought, under fair management, to furnish an adequate supply of dung for any of the usual courses of culture."

Having thus submitted to our readers all that occurs to us of importance on the subject of farm-yard manure, we shall here recapitulate a summary of the chief points which we deem particularly worthy of their consideration:

1. To bottom the farm-yard with furze, fern, dry haum, (stubble, &c.) or any other loose refuse that takes the longest time to dissolve; and over that to bed it deep with straw.

2. To occasionally remove the cribs of store cattle to different parts of the straw-yard, in order that their dung may be dropped, and their litter trodden, equally.

3. To spread the dung of other animals, when thrown into the yards in equal layers over every part.

4. To remove the dung from the yard at least once, or oftener, during the winter, to the mixen.

5. To turn and mix all dung-hills, until the woody fibrous texture of the matter contained in them,

and the roots and seeds of weeds, be completely decomposed, and until they emit a foul putrid smell, by which time they reach their greatest degree of strength, and arrive at the state of spit-dung.

6. To keep the dung in an equal state of moisture, so as to prevent any portion of the heap from becoming fire-fanged. If the fermentation be too rapid, heavy watering will abate the heat; but it will afterwards revive with increased force, unless the heap be either trodden firmly down or covered with mould to exclude the air.

7. To ferment the dung, if to be laid upon arable land during the autumn, in a much less degree than that to be applied before a spring sowing.

8. To lay a larger quantity on cold and wet lands than on those of a lighter nature, because the former require to be corrected by the warmth of the dung, while, on dry, sandy, and gravelly soils, the application of too much dung is apt to burn up the plants. Stiff land will also be loosened by the undecayed fibres of long dung, which, although its putrefaction will thus be retarded, and its fertilizing power delayed, will yet ultimately afford nourishment.

9. To form composts with dung, or other animal and vegetable substances, and earth, for application to light soils.

10. To spread the manure upon the land, when carried to the field, with the least possible delay; and, if laid upon arable, to turn it immediately into the soil.

11. To preserve the drainage from stables and dung-hills in every possible way, and, if not applied in a liquid state, to throw it again upon the mixen.

12. To try experiments, during a series of years, upon the same soils and crops, with equal quantities of dung, laid on fresh, and afterwards rotted; in order to ascertain the result of their application to the land. The whole quantity to be first weighed or measured, and then divided.

The fermentation of farm yard manure is, in fact, a subject of far greater importance than is generally imagined, for on a due estimation of its value mainly depends the individual success, as well as the national prosperity of our agriculture. The experiments to which we point, cannot therefore, fail to come home to the interests of every man; they may be made without expense, and without any other trouble than the mere exercise of common observation and intelligence. Leaving, however, aside the discussion concerning the disputed worth of fresh or fermented—of long or short dung—let the farmer sedulously bend his attention to the accumulation of the utmost quantity that it may be in his power to procure. The manner and the time of using it, in either state, must, however, be governed by circumstances which may not always be within his control; and every judicious husbandman will rather accommodate himself to the exigency of the case than adhere strictly to his own notions of what he conceives to be the best practice. In fine, whether favoring the one or the other side of the question, let him collect all he can, apply it carefully to his crops, and then trusting to events, "*let the land and the muck settle it.*"

SCRAPS OF INFORMATION IN REGARD TO THE CULTURE OF THE CHINESE MULBERRY.

In the present unparalleled and general excitement, in regard to the speculations in purchasing, and intended culture of the morus multicaulis, no apology need be offered to our readers for giving to that, and to kindred subjects, so much space in this publication. Indeed, whether viewed as a valuable future improvement in the agriculture and industry of this country, or as a subject of national mania, the subject is one of intense interest to almost all who read agricultural publications, and to even most persons who read nothing. Almost every one of our subscribers, stimulated by some one or other motive, will desire to cultivate at least a few plants; and all are but slightly informed on the subject. Therefore, in addition to the valuable general directions for the culture given by G. B. Smith, Esq., in the last No. we shall add here some interesting extracts from several private letters from T. S. Pleasants, an extensive cultivator of some experience, and whose general intelligence, and correctness of observation, deserve the fullest confidence. These letters were designed only for our own perusal and use; but considering the suggestions as interesting, and likely to be useful to many others, we have asked and obtained permission to share the benefit with our readers.

To these extracts will be added other scraps of information received from various sources, and principally from the Rev. Sidney Weller, of Halifax county, N. C.

It is gratifying that the favors of fortune, in this sudden and surprising mulberry madness, have fallen in some cases upon most worthy receivers; and there are none in whose successful and profitable cultivation we are more gratified, than in the cases of the individuals named above. In general, these unexpected visitations of good fortune have fallen upon a class of cultivators, who usually work more for the public benefit than their own, and whose improvements, or schemes, subject them always to ridicule, and often to loss. These are the book-farmers and experiment-makers—*and especially the regular and devoted readers of the Farmers' Register, or other agricultural periodicals.* To this last fact we desire particularly to call attention; and would be much benefited if it could be presented fully to the view of all who have made nothing from this golden harvest, simply because they had read nothing concerning the cultivation which has produced it.

We shall take the liberty of speaking more fully of Mr. Weller's case, because it is one of peculiar interest. He settled himself on a piece of miserably poor land, and with very little prospect, as his neighbors thought, to make a bare subsistence from its products. He has devoted himself principally to vine and multicaulis culture. Some notices of his useful services to agriculture, in the former department, have been heretofore given in this publication. Of the latter, the principal circumstances are as follows: Five or six years ago, being then, and long before, a regular reader of the American Farmer, he was induced by its recommendations (all of which we owe to its former editor, Gideon B. Smith,) to begin the cultivation of the multicaulis. He bought of J. J. Hitchcock, of Baltimore, a plant of about a foot in height, for which he paid a dollar; and 25 cents more for getting it to his residence. From this small beginning, all his stock, and many other, now large stocks, bought from him, have grown. Mr. Weller's sales of plants, before this season of speculation and high prices had commenced, amounted to about $2000; and, this fall, to $8000 more, though made at 6 cents the foot, and before the rise to half the present current prices—besides reserving enough stock to double or treble his crop next year.

Let it not be supposed from these or any other statements of enormous profits from raising multicaulis plants, that we design to have inferred as our opinion, that we expect them to continue. The greater part of the present price of multicaulis is undoubtedly a bubble, blown up by speculation; and that part must burst, sooner or later, (when, we cannot predict;) but the *intrinsic* value of the plant will remain; and if silk-culture should be really undertaken by only one farmer in every hundred, and the demand thereby created should maintain, for two seasons, the plants and buds to one-eighth (or perhaps one-sixteenth) part of their present exorbitant prices, the cultivation will still be highly profitable to all who plant even at the present high prices. If there should be *no demand* of purchasers, and *no design of the cultivator to raise silk-worms*, then of course he will lose his whole outlay. Of these, or of better chances, every adventurer must judge for himself.

We proceed to give extracts from our friend Pleasants' letters. *He* will not confine his efforts to merely raising mulberry plants for sale, but will feed silk-worms the next season, on a considerable scale. For this purpose, he has acquired possession of the Bellona Arsenal, in Chesterfield, which will be converted from its late warlike name and purpose, to a laboratory for the peaceful and useful labors of silk-culture, under the direction of its present worthy occupant.

* * * * *

"On the subject of *one-bud cuttings* of multicaulis, I can give thee my experience this year, which perhaps may be of some value. It is probably known to thee, that with scarcely any exceptions, there was a great failure in getting cuttings to start last spring. John Carter is the only cultivator I know who has succeeded well. Next to him, I place myself—but at a considerable distance in the rear. To the north, not more than one in 15 or 20 grew. The failure was owing to a most peculiar season, for I never saw cuttings start better than mine did. An excessive drought, at the time the plants began to root, dried them up. In preparing my cuttings, out of some of the strongest and best wood, I cut 10,000 or 15,000 with one bud. The remainder had two buds. The one-bud cuttings I planted to themselves in the same sort of ground with the others; and they were all subsequently treated alike. Taking the piece at large, they stand as well as the best spot of two-bud cuttings, and much better than the greater part of them. They come up with great regularity, and have grown off very evenly.

"If the season is propitious, there is no reason why a cutting with one bud should not grow as well as one with two buds. A large one may be stuck deeper in the ground, and in a drought, it may be longer under the influence of moisture. But with *early planting*, I have no hesitation in relying upon any good one-bud cutting; and early planting, by the way, is more or less important to the success of every mode. I have never taken up my multicaulis plants so early in the spring, but what I found the buds started, and the little rootlets in the act of being thrown out. The growth must therefore be checked by exposure to the air, and transplanting. From my observation, the conditions which I would recommend, (and which I rely on so fully that I intend to practice them,) in order to insure success to one-buds, are as follows: Preserve the plants during winter in a cool place, not exposed to the sun. Let the ground be prepared, so that the planting may be commenced as early as the season will permit; if in February the better—at any rate, early in March. The soil should not be so light or sandy as to become thirsty very soon. Let the cuttings be prepared by separating midway between the joints, and stick them deep enough for the bud to be covered from an inch to an inch and a half, according to the texture of the soil. The bottom of the slip will then be about $2\frac{1}{2}$ inches beneath the surface—a depth to which the ground seldom becomes entirely dry in the early part of the spring—and if there be any choice of ground in the lot, select for single buds that part which lies the lowest, as being likely to retain moisture the longest. With these precautions, and above all, *early* planting, no failure can, in my opinion, ensue; but I would advise thee to consult other cultivators on the subject. By a strong cutting, I mean one taken from the larger part of the main stem of a vigorous plant, and those near the base of thrifty lateral branches. Some days ago, I removed the earth from a number of my single-bud plants, for the purpose of examining them carefully. I found some smaller than I intended to plant; but the trees were as large as those from the largest cuttings. * * * * *

"My plants will this year yield *per cutting* about 40 buds, on the average—perhaps more; and the most of them grow on a thin, shallow soil, that never was manured." * * * * * *

"It is the opinion of many men of judgment, with whom I have conversed and corresponded, that the present prices will be nearly or quite sustained another year. The stock of mulberries is not so large as one might suppose. There are very few in New England. A friend in Baltimore informs me that G. B. Smith estimates the number in the United States at two and a half millions. Robt. Sinclair (perhaps in conjunction with Smith,) states the same number; and a friend of mine, who has taken great pains to inform himself, has arrived at precisely the same conclusion. I cannot help thinking there are more; but my information on the subject is not extensive. In regard to the demand, I may say that, in addition to that indicated by the present high prices, Judge Comstock, editor of the Silk Culturist, told me he did not think there were more in the United States than would supply the state of Connecticut, at fair prices, if they were all sent there. And a gentleman of Burlington informed me that there were not more than enough in New Jersey to supply the present demand in the county of Burlington in the same manner.

"I intended to have said a word about sprouting cuttings in a hot bed, as recommended by G. B. Smith. I have only tried it once, and then on a small scale; but I did not succeed very well. The objection is, that the plants become chilled and stunted by removal from such comfortable quarters, to be exposed to the inclemencies of the month of May. But in any event, great skill and attention are requisite in the management of a hot bed.

"It may be very familiar to thee, but it will do no harm to add, that the most convenient instrument in preparing the cuttings, is a pair of pruning scissors—such as are used by vine dressers."

* * * * *

"I had intended to supply an omission made in regard to the preparation of cuttings; and the remark I would make, applies especially to cuttings of single buds. It is the main stem that I recommended to be cut into single buds, and it is the strongest part of the stem that throws out the lateral branches. As every lateral starts out, there is no bud (at least none that will readily grow,) remaining at the joint; and it is therefore necessary, in preparing the cuttings, that the lowest bud on the lateral should be left to the main stem. I lost many plants last spring by not attending to this. And the sellers of mulberries, who supply *trimmed* plants, should always prune in this way; otherwise, the best portion of the wood on the whole plant will be of little value.

"I have almost determined to plant a portion of our cuttings *this fall;* say about the last of Nov. or 1st of December. The slightest covering of earth, I have always found to be sufficient to protect them during winter. If thou hast noticed the plants in the spring, when they are uncovered for the purpose of planting, especially if it be not very early, thou hast no doubt observed that every good bud has sprung. By exposure to the dry air, many of them perish before they are planted. Had they remained under a proper depth of soil, every bud, starting as they do at the same time, would have shown itself above the ground. Why cannot they be protected in the field equally as well, without being subjected to spring handling and removal? It would be an easy matter to cover the stems in the furrows 2 or 3, or even 4 inches deep, and remove the covering in the spring, which would be a good working. I have been thinking all the summer I would plant a portion of my crop in this way; but I should be afraid to recommend it strongly to others, lest there might be a failure. If, however, it should succeed as well as I am convinced it would, almost every bud would produce a tree; and by vegetating earlier, it would produce a much finer tree than by the common mode. I perceive that Cheney, who is a very experienced cultivator, recommends that *layers* should be planted in the fall. At all events, I know from experience that the earliest spring planting is much to be preferred to deferring it until the ground becomes somewhat warm. Like grains of early planted corn, the cuttings are throwing out roots, though the germ may not appear above ground, much sooner than the late planting. Unless the ground was clean, there might be danger from the field mice. Please to give me thy views on this subject.

"Wilt thou take it amiss, if I venture to assign one or two reasons why thou shouldst not offer thy plants of 1839 for $12\frac{1}{2}$ cents, as thou didst propose doing some time ago? I would not deter thee from doing so, for the purpose of keeping up the price. If they do not sell for more than 9d. I shall be perfectly satisfied. It is enough for them. But can any one individual reduce the market price by offering his crop at reduced rates, or even by giving them away? Perhaps thou mayest grow a million. If there be a brisk demand for 20 millions, which will probably be the extent of the supply next year, a million more or less will have very little effect upon prices. By contracting now to receive much less than they will probably command, thy efforts to reduce the prices will be unavailing, and thou wilt be voluntarily depriving thyself of the profits to be derived from the culture. Speculators, also, might buy up thy whole crop, and retail it at greatly advanced rates. Indeed it is only the speculator, perhaps, that would now contract to receive plants to be delivered a year hence. So that I see no probability of thy effecting thy object by this course. It is however very possible that by another year, public feeling on the subject may be more rational, and that prices may correspond with the actual value of the plant for the purpose for which it was designed by nature. We are now going through the paroxysm of the fever; in due time it will abate, health will be restored, and reason resume her empire. Let us wait patiently for it, and do all we can to promote the culture of silk, until the question is settled whether or not it can be introduced into this country as a profitable branch of agriculture."

* * * * *

"I think I have obtained some valuable information respecting the action of bone manure in growing mulberries. When I was at the north, I inquired particularly about its general value, at Boston, Philadelphia and Baltimore. At Boston, there is a very large manufactory. At all three places, the price for crushed bones is 35 cts. per bushel. I purchased 200 or 300 bushels in Baltimore; but it was not until after I left there, that I heard of its good effects on mulberries. A grower in Burlington had applied some to a small lot of ground; and the effect was so beneficial, that I heard the trees spoken of as being the finest in the whole country. They had tried to keep the knowledge of it a secret there, for their own advantage; but I intend that it shall be known. I am promised the result of another experiment. I am fully convinced that with the use of \$5 worth of bone manure to the acre, our highest and driest, and poorest lands may be made to produce trees 5 or 6, or 7 feet high.

"Please inform me what was Sydney Weller's mode of saving his immature cuttings. I heard thee detail it, but perhaps I have forgotten some part."

In answer to the foregoing inquiry, and for the benefit of all others of our readers, the information derived from Mr. Weller's statement of his practice will here be given.

All who have observed the morus multicaulis, know that the plants of one year's growth have a large proportion of the latest formed stem and branches so green and tender as to be unfit to withstand severe frosts. This part of the plants, (with all the buds thereon, though frequently amounting to one-fifth, or more, of the whole number on the plant,) has, until lately, been deemed worthless, and taken no account of in sales, or in planting. But in our own small practice, it was observed last spring, when the plants were taken out of the earth under which they had been kept through winter, that the unripe buds, to the very extremities of the twigs, had begun to start in growth, and of course that they possessed enough vital power to produce plants, if properly managed. The proportion of unripe wood this year is unusually great, owing to the early and continued drought of summer having been followed by abundant late rains. After the first year, there is very little of the wood left unripe, as the branches generally ripen to the ends.

Mr. Weller had earlier learned the vital power and value of these unripe buds, and has practised with success the following manner of saving them separately. As soon as there has been frost enough for the leaves to fall off, and before any more severe cold weather follows, all the unripe ends of branches and stems are cut off, including about an inch, or one bud, of the adjoining ripe wood below. These are laid in a shallow pit or trench, or even on the cleanly scraped surface of the earth, so as not to be more than four inches thick; and then are covered over with clean and friable soil, (sand would be better,) which is to fill up all vacancies between the twigs, as well as to cover them. Then, any kind of earth may be heaped on, so as to cover the twigs 12 or 18 inches deep, if freezing is feared; though a few inches depth has always proved sufficient. As in all other cases of winter-pits or trenches to contain multicaulis plants, the access of too much water from rains should be prevented, by choosing an elevated spot, or surrounding it with a ditch. Mr. Pleasants' views and advice as to choosing a *cold* situation, to prevent the too early springing of the buds, are likely to give still greater value to this practice of saving and using unripe buds. Mr. Weller relies on his unripe buds, saved as above, to be nearly as certain as the ripest, to vegetate and produce well; and this information may be worth several hundreds of dollars, this year, to every one who has as much as an acre in multicaulis plants. It is highly necessary to avoid having any vegetable matter in contact with the buried twigs; as mouldiness and rotting will be produced, and perhaps may spread beyond the twigs first affected.

As to the capacity of the unripe buds to germinate and to produce good plants, if preserved properly through winter, (without being cut from the plants,) we knew it likewise from the information of John E. Meade, esq., of Prince George, who availed of the knowledge so well that he has now as many growing trees as he bought cuttings last spring—the unripe buds, which were not charged, having fully made up for all the failures of the ripe. By the way, the cuttings bought by Mr. Meade last spring, cost him (at an unusually low price) $10, and the crop from them is worth $1000, at the present enormous prices and ready sales.

We saw Mr. Weller's nursery, (in Halifax county, N. C.,) on October 16th. Tender plants, (such as sweet potato vines,) had then been partly killed by frost, but his mulberries were barely touched, on some of the youngest top leaves, and may grow, or ripen, much more yet. He had worked the ground as late as in August; and that, (as we think, improperly late cultivation,) as well as the late rains, had caused a very late growth, and an unusually large proportion of unripe wood and buds. He does not trouble himself to cut down and cover, or to use any other means to protect in winter, any of his plants, except the unripe extremities of branches. He considers all the ripe wood as perfectly safe. This is a most important advantage of the climate of North Carolina and Virginia. But though cutting down the entire plant is unnecessary to protect the ripe wood from cold, still as it will be done at any rate, for cuttings, while the great demand lasts, it will be better to cut off and bury the entire stems and tops, to better protect the unripe buds.

Mr. Weller's nursery ground is quite sandy, and it had been very poor, and most of it is now far from rich. Yet his one-year's plants are generally four and sometimes six feet high; showing the great advantage of using the lightest soil. At Gaston, on the rich as well as light soil of the Roanoke low-grounds, a small patch, belonging to W. W. Wilkins, esq., would average certainly 150 good buds, (and he thinks 200) on the plants of this year's growth. It is certainly the finest growth we have seen. These plants, from buds planted last spring, in seven months thereafter would readily sell for $3 a-piece—perhaps for $5, at the present prices. Some waste building lime had been given to this spot. We had been before inclined to believe that calcareous manures are peculiarly adapted to the mulberry, from having observed the usual locations, and degree of luxuriance, of the native growth. Mr. Weller has found very decided benefit from sprinkling the rubbish of old mortar, (from demolished brick-work,) in his rows of multicaulis cuttings. The great value, too, of bone-manure, (though bones are of phosphate of lime,) as stated by Mr. Pleasants, is a valuable fact, and helping to confirm the opinion of the demand of this plant for lime in some of its forms of combination.

Mr. Weller plants at any time in winter or spring, when he has the time. He has no objection to, or fear of, fall planting, but has no spare labor at that season. He cuts up, generally, into single-bud cuttings, and drops the bits into the furrow, with no care as to their position, and about seven or eight inches apart, (rows three feet) and covers carefully. We think a better mode would be to stick the lower end of the cutting into the soft mould, perpendicularly, and to cover the bud not more than an inch, if near the time to sprout. The lower extremities, where the roots form, in this case would be as low as possible, and so much the more likely to keep moist; and the bud be very near, as it ought to be, to the air. These objects will be still the better answered, by cutting the branches as close *above* each bud as is safe, and of course giving as much length as possible of each cutting *below* the bud.

Besides the rapid mode of propagation from single-bud cuttings, when they are allowed to have the growth of an entire season, there is another process which may be added, and by which the product may be still more and greatly multiplied. This is by *summer layers;* which mode is extensively practised by some of the largest dealers and nurserymen, and which is certainly an admirable means of making profit by imposing on distant and ignorant purchasers, still more than to obtain the legitimate gain of the actual increase of the stock of plants. As described to us, the following is the most approved and productive plan of raising from layers. Early in July, or as soon as the young shoots are 10 to 15 inches high, let each be bent down and laid on the earth, and confined there by a forked stick, and a little earth be laid on one of the buds near the extremity. The leaves of the buried buds should be cut off. From there roots soon strike out, and each extremity runs up rapidly into what northern nurserymen call "a tree." Soon after the first operation, every alternate bud, of the stem laid down, should be covered with earth in like manner; and from each of the intermediate buds, left uncovered, there will be thrown up other upright shoots, of which the connecting original stem may be cut apart, before the growing season is over, and thus form so many of what are termed "rooted and *untrimmed* trees," and sold as such, formerly at 25 to 38, and now at 60 cents or more, a-piece. In this manner, in a good season, and during rapid growth, we are informed that sometimes six, or eight, and even ten "rooted trees," may be raised in a year from a single bud planted the same season. This is a very useful practice to increase a small stock rapidly; as these secondary, though very inferior plants, if well preserved through winter, will furnish a greatly increased stock of buds and roots for the next year's planting. But *to sell* these plants, of half a season's growth, to distant purchasers, as "rooted trees," without explanation, is a gross fraud, which has been most extensively practised already, and by which hundreds of thousands of dollars have been, and will be, unrighteously gained. From this description many purchasers of plants will now understand the manner in which their supplies were produced. For plants from layers must necessarily be of small height, the growth late, and a large proportion of the stem unripe—and always without branches, (though sold perhaps at nearly double price for being "*untrimmed*"—) and the roots, consisting of a small horizontal bit of the original stem converted to root, with merely a few thread-like rootlets extending therefrom. Purchasers should guard against receiving the products of layers as "rooted trees," whether sold as "untrimmed" or not.

Cuttings, also, may be separated from young plants in any wet season, during summer, and, if set out immediately, will live, and form separate rooted-plants. We are inclined to believe that the *topping* of young plants, for this object, in July, would be useful, by causing more extension of side-branches, and better maturing the buds on the extremities.

Among the great and unexpected products from this year's growth of mulberry plants, there will be an abundant harvest of law-suits. We know of several having been already commenced; and hundreds of others will follow. There will be many novel points of agricultural law for the courts to decide, which will be curious; and not a little amusing to all except the litigant parties. All persons who make contracts, should be very cautious as to the other party with whom they deal, and the manner of fixing the conditions.

We will close these scraps of information with some arithmetical calculations and estimates, which perhaps may be of service to readers who design either to buy or to sell, or who are in possession of multicaulis plants. We have had reason to be surprised to find, in sundry cases, how little had been done, even by dealers to large amounts of money, in the way of estimating arithmetically, the present or prospective amounts, or market prices of their possessions or purchases. It is, therefore, that we have thought that these *mulberry statistics*, and estimates, trifling and humble as they are, may not be useless.

On page 592, vol. II, of Farmers' Register, and in the appendix to the 'Essay on Calcareous Manures,' (pp. 103, 104,) there is a table of the number of plants, or rectangular spaces, in an acre, at every distance that can be desired. This will be found far more convenient for reference to show the number of mulberry plants to an acre, than for the other purposes for which the table was originally designed.

According to this table, an acre of land planted with cuttings at the distance of three feet by one, would take 14520 plants. This allows abundant space for the first year's growth. At three feet by eleven and a half inches, there would be 15125 plants; and therefore, for round numbers, 15000 may be taken as the number of cuttings proper for an acre, and which, if not growing unusually large, would not be too thick, even if all were to live. Upon this ground, the cost and returns (and *conjectural* profits) will be estimated.

Cost.

15000 single-bud cuttings, bought November, 1838, at $2\frac{1}{2}$ cents each, make the cost for an acre, - - -	$375
Interest on $375 for a year, - -	22
Keeping cuttings through winter and cultivation in 1839, - - -	25
Rent of land, - - - - -	18
Total cost, - -	$440

Profit.

Suppose of 15000 cuttings, 6000 to fail, and only 9000 trees to grow, and these to average only thirty good buds each—and these buds to sell in November, 1839, at but half a cent each; then the product will be,

9000 plants, $\times$ 30=270,000 buds $\times$ $\frac{1}{2}$ cent, - - - - -	$1350
9000 roots, at three cents each, -	270
Gross product, -	$1620
Deduct cost, - -	440
Leaves, upon these data, clear profit, -	$1180

This profit, or even half as much, ought surely to satisfy the most eager; and as every expense is charged full high, and the failures allowed are far too many, for an average season, (and even if such unusual loss should occur, the vacant spaces might be filled by summer layers,) there is nothing wanting to almost insure the full profit, except *this one datum, that buds next fall shall be worth half a cent each.* Of this chance, we leave each one to judge or conjecture for himself. If, as most persons now believe, the price should be much higher than the above-stated, there would be more than a proportional increase of net profit, as no more expense will have to be paid; and if the present enormous prices of the cuttings and roots should be maintained in the next crop, (say $2\frac{1}{2}$ cents the bud, or 15 cents the foot,) then the gross product of the acre would rise to the almost incredible amount of - - $8100

And, deducting expenses, -	440
The net profit would be, -	$7660

Enormous as is this statement of profit, it is believed that it has been actually equalled this season in sundry cases. The most remarkable example, in which it is believed that these profits have been fully equalled, is in the large nursery near Richmond, cultivated by William Kenrick, a nurseryman of Newton, near Boston; though under all the disadvantages of cultivating by agents, and on rented land, so many hundred miles from his residence.

SOME ACCOUNT OF THE INTRODUCTION OF THE MORUS MULTICAULIS INTO THE UNITED STATES, AND THE DIFFUSION OF THE KNOWLEDGE OF ITS PECULIAR VALUE, AS FOOD FOR SILK-WORMS.

In the foregoing article, it was stated, that the profits of cultivating the morus multicaulis, (not meaning the profits of speculation,) have generally fallen to individuals who are the most disposed to read, and to pay respect to the information of, books or other publications on farming; and who are the most ready to try the experiments and new improvements therein proposed, or made known. But, to this general rule there is one remarkable exception, which it is our purpose to present, and in the hope that a proper sense of gratitude and justice will prevent this exception remaining much longer in existence.

To Gideon B. Smith of Baltimore, more than to any and to every other individual in this country, are the country at large, and the fortunate individual cultivators in particular, indebted for the possession and enjoyment of the value of the morus multicaulis. He was one of the earliest possessors—the very earliest, to investigate, and to learn its value, from foreign publications and from his own experiments; and while most other persons were either ignorant or careless of the value, or, when better informed, cultivated the plant solely for self-interest, Mr. Smith was, and has continued to this day, without reward, or any hope of remuneration, the zealous and unwearied advocate for the dissemination and use of this tree. He has gained, in pecuniary reward, no more than he expected—that is, *nothing*; and it would seem, that efforts have been made to take from him even the credit of his voluntary and gratuitous labors, and to assume the merit not only of superior intelligence in this respect, but of *disinterestedness*, and *public spirit*, of which the claimants have never had the slightest conception.

It is not the *market value* of this article which Mr. Smith has had any agency in establishing or increasing, except so far as this factitious and speculative appreciation is certainly founded on a real intrinsic value. He has had no hand in stimulating the present rage for speculation and, on the contrary, has done what he could to allay it, and prevent the greatest excess of the mania. And he has gained as little by the speculation, and its high prices, as he had by the cultivation. He still owns the oldest tree in the country, from which so many entire and large stocks of trees in the south have been derived; and that is very nearly all that he possesses of the growth. He has sold, or advertised to sell, multicaulis trees; but it was as agent for another, one of whom has made a princely fortune from this source, and who did not even leave to the agent the promised compensation. This circumstance we have heard from another source, and not a hint of it from Mr. Smith. But most of the following particular facts, in relation to the introduction and establishment of the value of the multicaulis, have been obtained from him, in answer to our recent and special inquiries, but without his having been informed, or having any ground to suspect, the object to which we designed to apply the information. Delicacy did not permit any such disclosure; and we fear that he may think that delicacy should also forbid the manner in which it is now made, to himself and the public together. But if so, we hope that the mode may be pardoned in consideration of the object. He knows nothing of this piece, nor of its special or main design; nor will he know, until, by its publication, it must necessarily reach him. It was only as to particulars that it was necessary to direct our inquiries; because we before knew well, in common with most of the readers of agricultural papers, the general fact of the services, in this respect, which Mr. Smith had performed; and suspected that they had been rendered without compensation in any form.

Before proceeding with the statement of facts, we will quote some passages from recent publications, because in some slight degree bearing on the subject of these remarks. In the Richmond Enquirer of October 12th, there appeared a communication (signed J. W.,) on the culture and sales of the morus multicaulis, containing the following paragraphs:

"To the Editor of the Enquirer.

"At your request, I communicate the following views in reference to the introduction, mode of propagation, rise and progress of prices, and the re-production of the 'morus multicaulis' or Chinese mulberry.

"1*st. Introduction.*—I believe we are indebted to our worthy fellow-citizen, Dr. Norton, for the introduction and gratuitous dissemination of the morus multicaulis in this country.

"2*d. Cultivation.*—The cultivation was commenced in this vicinity by Dr. Norton, about the year 1828; by Mr. John Carter about the year 1830, and by a few other gentlemen in 1832 and 1833."

* * * * * *

"Other gentlemen may have imported into this country the morus multicaulis, and its dissemination may have been enlarged from other sources; but I am of opinion, that from the nurseries in this vicinity, were the supplies principally, if not altogether derived."

The balance of the communication relates to the propagation, sales, and present profits of the trees, and has no bearing on our subject. The Richmond Compiler of the 13th, re-published the entire article, with additional comments, from which the following sentences are copied:

"In our article a few days since, on the subject of silk-culture, we stated, that our vicinity had done its full share towards the introduction into this country, of the morus multicaulis or Chinese mulberry, so useful in the raising and support of silk-worms. We stated that our worthy citizen, Dr. Norton, was among the first, if not the very first, to cultivate it. These opinions of ours are sustained by a letter in the last Enquirer, addressed to its editor, in reply to certain queries connected with the silk-culture. We are glad to find that we were correct; and that to Virginia belongs the credit of having been foremost in a matter, which is to confer a lasting and important benefit upon the nation." * * * * *

"The cultivation of the morus multicaulis with us is a source of great profit, owing to the better adaptation of our climate and soil to it than any north of us; and we owe Dr. Norton many thanks for having introduced the cultivation of it here." * *

Now, though we have resided for years within no great distance from Dr. Norton, (besides our intimate acquaintance with, and frequent presence in, Richmond,) and though we are anxious at all times to give due credit to benefactors to agriculture, and especially to render all due honor to the improvers of Virginian agriculture, we had never before heard of this claim to the merit of having introduced the culture of the morus multicaulis. It is very true, that neither of these articles is *written* by Dr. Norton, (nor the still earlier one referred to above. which escaped our notice,) and therefore, no matter how incorrect, he cannot be held responsible for their *first appearance*. Neither can the anonymous writer in the Enquirer, nor the editor of the Compiler, be blamed for giving to *him* the credit, which they deemed, on report doubtless made to them, to be his just due. *But this we maintain*—that no contradiction, or explanation, or waiving of the undeserved honor, having been published by Dr. N., even to this day, he has, indirectly, but most fully, sanctioned the claims made for him in both these publications.

In our letter of inquiry to Mr. Smith, we directed his attention to these publications. The tone of his answer is, naturally enough, somewhat *tempered*, by the very unexpected discovery of a new competitor for the only reward which he thought he had earned—the honor of bringing the multicaulis into notice and extensive use, and *possibly*, also, some feeling of gratitude from the individuals who are growing rich from having known better than himself how to profit by its pecuniary and trading value. Under such circumstances, his tone may well be excused.

The answer of Mr. Smith, (dated October 16th,) says—

"The history of the introduction of the morus multicaulis is as follows. When Congress passed the resolution instructing the Secretary of the Treasury to collect information on the subject of silk culture, Wm. Prince & Sons, of New York, wrote immediately to Marseilles, in France, to their agent, ordering all the books on the subject, and specimens of all the mulberry trees known there in use for silk, to be sent them. This was in the year 1826, and the plants arrived January 7th, 1827. Among the trees received, one variety was called the *Philippine Island mulberry*. Messrs. Prince immediately sent me one tree of each of the kinds they received, amounting, I believe, to 15 kinds. The Philippine Island mulberry, proved to be the tree subsequently named the morus multicaulis. A year or two after I received these trees from Prince, the French papers published notices of the valuable qualities of the morus multicaulis, a tree just introduced by the enterprising Perottet, describing its characters minutely. On reading those descriptions, I immediately discovered that our Philippine Island mulberry was described as the multicaulis, and wrote to Mr. Prince to that effect, and at the same time informing him that I had used it for feeding silk-worms, and found it to be every thing the French writers had described it to be. Prince concurred with me, and propagated the tree for sale, and has done so every year since, besides importing from France more trees each year than ever were produced in Virginia altogether, until the present year. Dr. Pascalis, of N. York, in the spring of 1830, received three trees from France, one of which he gave to my old friend Parmentier, then of Long Island, one to Dr. Hosack of New York, and one to some one unknown to me. The above is a circumstantial and true account of the introduction of this tree into this country, and of the discovery of its valuable properties. Messrs. Prince's old tree occupied a place in their nursery till the fall of 1837, as an old stool for layers; my old tree yet remains in my garden, where it will continue while I live, as it is the oldest, and was one of the first trees in America. So soon as I discovered the valuable qualities of the tree, I commenced propagating it and distributing to every one whom I could persuade to take it. I gave it to every nurseryman in Baltimore; sent it to the south and west, and indeed every where, where I could induce people to take it. I can say freely, that were I paid down for all I then gave away, at the present prices, I should have money in my purse, instead of being, as I am, out of pocket no small sum, on account of my efforts to introduce it into the country at large. I never kept any memorandum of the trees I gave away, nor of the persons to whom I gave them; but I can adduce the testimony of every nurseryman in Baltimore, (and of the country at large, I might say,) to prove, that the celebrity of the tree is due to me, and that, for six or seven years, I was *alone* in the effort to introduce it. I gave trees to Mr. Samuel Feast, Mr. John Feast, Mr. Robert Sinclair, Mr. James Wilkes, Mr. Bastien, and numerous others, all regular nurserymen, in 1829, or 1830, with urgent recommendations to propagate them extensively, "for the time will come when you will make your fortune by them"—my invariable remark to all. I was laughed at by all; and, from all quarters, was called "the mulberry madman," "the silk-worm maniac," and all that sort of thing, for my pains; but still I persevered until I waked up the sleeping lion effectually." * * * * * * *

Mr. Smith, as editor of the American Farmer for several years, and, indeed, for several years before, (as far back as 1826,) had been urging the value of silk-culture, and the propriety of propagating the mulberry. His editorial influence, (which, for this purpose, was used before he was ostensibly an editor of an agricultural journal,) gave him the greatest facilities for disseminating his opinions on the general subject; and as soon as he had learned the value of the multicaulis, all his zeal was enlisted in aid of spreading the plant itself, and a knowledge of its value, throughout the United States, and even beyond the limits of this country. Another passage of his letter says,

"When I had satisfied myself of its qualities, I began to publish my opinions, and they will be found in the American Farmer, from 1831 to 1834 inclusive, as well as in almost every other agricultural journal in the country. My public writings, however, did not comprise one hundredth part of my labors in the cause. It was by private correspondence I did the great amount. I was incessantly plied with letters from all parts of the union, making inquiries in relation to the best kinds of mulberry trees for silk-worms; and in answer to them all, I invariably recommended the morus multicaulis, *when there was not another man in the country*, except Mr. Prince, Dr. Pascalis, (who merely adopted the opinions of his friends in France, having no experience of his own,) and Mr. Parmentier of New York, who agreed with me. From the summer of 1830, to the present time, I must have written some thousands of such letters. Great numbers of these answers have been published in the local newspapers, where they were received, and of course multiplied greatly the number of inquirers. I have often had five to ten letters a day, from that time to this, to answer on this subject—for, be it known, the present mania has not lessened, but, on the contrary, materially increased my correspondence on this subject. The great burden of my labors has therefore been unseen by the public; but still, the public has seen enough in the public prints, besides all this, to award to me the credit of being *the* promoter of the culture of morus multicaulis in this country. So universal is the opinion that this credit belongs to me, that strangers, whom I never saw nor heard of before, have frequently called on me to inspect the leaves of my trees, fearing they had not obtained the right kind, and supposing that I was the original importer of the tree. Many persons have come to me from a distance, to get trees from me, to be certain of getting the genuine ones, when they could have got them at their own doors for far less expense. I have sent the trees to South America, to Cuba, Jamaica, and to several places on the Mississippi river, all gratuitously; for having been applied to for information on the subject of silk, and the best kind of trees, from those places, my recommendation of the multicaulis was always accompanied, when a conveyance offered and the season admitted, with at least one tree, or cuttings.

"Another point. The facility of cultivating, and particularly of propagating the tree, was discovered by me. When I received my first tree, an accident befel it that was nearly fatal. It was growing in my garden with 15 other kinds, and I was feeding silk-worms with every spare leaf I could get from it. In 1829, I believe, about the first of July, I discovered one morning, that the leaves were all turning yellow. Knowing its value, I was considerably frightened, and immediately wrote to Messrs. Prince to send me another tree, as mine was dead. Late in the season as it was, they did send me one, that was growing in a flower pot with an oleander; I presume they had put a small cutting there accidentally. But, as soon as I had written to them, I went to the garden and examined the tree carefully, and found that a nest of ants had surrounded the tree and perforated the trunk at the ground, through and through, and that it was dead 5 or 6 inches from the ground, but that the whole top was yet sound. I took a spade and dug a trench south of the tree, intending to layer it; in the hope that I might make it take root again, and thus save it. On bending it down, it broke short off near the ground. On this occurrence, my wife and other persons looking on, observed that I *"turned as pale as a sheet;"* I mention this to show how much I then thought of it. I, however, covered up the tree, turning up the end of each branch just above the earth, watered it well, and never looked at it again for two or three weeks—I never can bear to look at my misfortunes, it hurts my feelings—and then I was led to it by accident. When I did visit the spot, I was astonished to find the ends of all the branches I had turned up had made considerable growth. That fall I had 8 young trees, larger than the original plant. That gave me my first idea of the facility with which it can be propagated. I afterwards adopted the single-bud system of propagating, with which you are well acquainted, and practised it for two years before the public knew any thing about it. I did not publish this mode of propagation for several years, thinking to make something out of it for myself, but communicated freely *privately* to others, and before I knew what I was about, they had got all the advantage of it, and one of them even claimed the credit of its discovery in the public papers, just as another person now claims credit even for introducing the multicaulis into this country!

"In conclusion—it is to *Wm. Prince & Sons*, of Flushing, N. Y., that the credit is due of first introducing this valuable plant to the country; to whom the credit is due for discovering its valuable qualities, the great facility with which it may be propagated, and bringing it into general notice, indeed making it what it now is, I leave you to judge.

"I must now apologize for this long answer to your inquiries, filled as it is with selfishness and egotism. On reflecting on what I have written, I feel ashamed of my answer. Why should I attribute any importance to the thing? Do I not know that there never was a pioneer in any thing that got any thing but his labor for his pains? Look at Whitney with his cotton gin, Fulton with his steamboat, and all others of the same genus. I must therefore be content to have labored for the public, and let others receive the credit of it, as well as the pecuniary consideration.

* * * * * *

"One more explanation. I have intimated that I have never made any thing by morus multicaulis. I mean to be understood as saying, that I have never made as much as it has cost me. I am a loser by it. I do not wish to be understood as never having sold trees. I have sold a few every year for four or five years past. The largest lot I ever sold of my own raising, was 150, and the largest number in any one year of my own was 150. I have also made, as agent for others, $400 to $500 altogether, in commissions on sales."

And now to recapitulate, and to conclude.

To the intelligence, zeal, and untiring efforts of Gideon B. Smith, the people of the United States are mainly indebted for now possessing, and knowing the intrinsic value of, the morus multicaulis; and for the greatly increased facilities which its possession offers for making this a silk-producing country. If rewards were given in this country by government, (state or federal,) for distinguished services rendered to agriculture, then might a strong claim to honor and reward for this individual be made on the gratitude of his country, to be responded to by its government. But such not being our system, he, like the greater and more distinguished national benefactors whom he mentions, as well as all other pioneers in agricultural and mechanical improvement, must alike go without national rewards. But, in this case, there is another rich source, and which ought to be as liberal as it is rich, from which something may be hoped to be drawn. In the present strange condition of things, every cultivator or owner of a multicaulis nursery has suddenly found himself made richer by some thousands of dollars. Many persons, within a few months, have thus gained their thousands—some few their hundreds of thousands. If all, or if even the more liberal half of the many individuals thus benefited, would contribute to a joint fund only *one dollar in each hundred of their clear gain* so made, by the increased market value of their multicaulis plants, it would constitute a reward for the man who has been the chief agent in producing their good fortune, both large in amount as a pecuniary compensation, and still more precious as an honorary distinction. Let all such persons, then, who approve the plan, unite with us in making up such a fund. We offer to receive, and to be accountable for contributions in payment for any such debts of gratitude, and to dispose of the amount, under the direction of a committee of the principal and most accessible contributors, in such manner as may be supposod will render the reward most acceptable to the receiver, and most useful to the public. We have already proposed this plan, verbally, to several of the fortunate persons concerned; and all have approved the object, and most of them will aid in carrying through the plan. We invite all the fortunate possessors of multicaulis, and speculators in sales, to contribute to the fund, and to place their names, and the amounts subscribed, as speedily as convenient, at our disposal. To commence the list, we will subscribe $100: and whatever may be the degree of success, the plan will be executed to the extent of the subscriptions which may be offered and paid.

In advance of a more general publication, a copy of this appeal will be sent to every known and large recent possessor of multicaulis plants. From many of them, and of the far greater number unknown, whom it may reach accidentally hereafter, early and generous responses are hoped to be received. The names of the subscribers, and the amount of their subscriptions, will be announced in each successive publication of the Farmers' Register; and a suitable disposition of, and accounting for, the whole amount subscribed and paid in, will be made, as soon as may be directed by the committee chosen for that purpose, in the manner stated above.

The most appropriate disposition of such a fund, in our opinion, would be the following: Let a snug and productive little farm be bought, some acres of it planted with multicaulis cuttings, and a good cocoonery erected, as well as the other fixtures necessary for a silk farm; and when all the essential arrangements are made, let the farm, (for which "Gratitude" would be a suitable name—) be given to Gideon B. Smith. If, when thus provided with the means, it should suit his wishes and convenience to devote his labor and time to silk-culture for his own benefit, with even half the zeal and perseverance with which he has long been laboring to introduce and establish it for the public interest, he will be still farther, and greatly, serving the public weal, by furnishing example, and practical instruction, in this new branch of industry, to the region in which the farm will be situated.

Ed. Far. Reg.

From the Genesee Farmer.

IMPROVEMENT IN THE MANUFACTURE OF FLAX.

The August number of the Journal of the American Institute—a work we most cordially recommend to the patronage of our readers—contains a letter from J. F. Schermerhorn to the commissioner of patents at Washington, describing a new mode of manufacturing flax, or rather so preparing it for manufacture that it can be spun on the common spinning jenny as easy as cotton, and converted into cloth with the greatest facility. Mr. S. Olcott of New Hope, Pa., is the inventor of the process, and should further tests and trials but realise a small part of the benefits indicated, it will prove a discovery of immense value to the north and west. The flax, as we understand the letter, is by a short and simple process, and with the aid of machinery, converted into what Mr. Olcott calls his short staple flax; is deprived of its gluten and coloring matter, and bleached, and is then ready for spinning.

Specimens of the thread made from the prepared flax, as well as samples of the flax itself, were left at the office of the Institute, and attracted much notice from their beauty and strength. The only objections started, were that by being made into short staple, the thread lost the smooth silk-like appearance belonging to the unbroken fibre, and appeared more as if made of bleached tow, or rather of floss silk. When we reflect, however, on the smooth thread made from cotton, a material still shorter in fibre, and far inferior in strength, there can be no reasonable doubt that in the process of manufacturing linen cloth from prepared flax, methods of obviating this and other difficulties will be easily found. In the language of the Journal, this improvement, "must produce a wonderful advance of productive industry in our portion of the union. In the west it will open mines of wealth. If flax can be produced and prepared for the spinning jenny as cheap as cotton, and converted into cloth as readily, then the northern and middle states can avail themselves of a great staple that will vie with the south; and this may be done at once, for we already know how to spin. It is not like silk, which is sure to succeed eventually, but progressively. The mulberries must have time to grow; and the knowledge requisite for managing the silk-worms, taking care of the cocoons, reeling, &c. will require time to be generally adopted and understood."

Mr. Schermerhorn makes some interesting estimates of the profits that must ensue from the production and manufacture of flax. We have room for only the following:

"1. Estimate for buildings and machinery to manufacture 1000 tons of short staple flax, $30,000
The actual expense of preparing 1,000 tons of fine flax; including the raw material, at $250 a ton, - - 250,000

$280,000

Now if we estimate this short staple flax worth fifty cents per pound, which will not be deemed an extravagant price when it is remembered that every pound of such fine flax will make between four and five yards of fine linen, say four yards, and this can be made into fine linen at about four cents per yard: then 1,000 tons being 2,000,000 pounds will be worth at 50 cts. per lb. - $1,000,000
Now deduct from this as above for buildings, machinery, raw material, and expense of manufacturing the fine flax, at 250 dollars a ton, - 280,000

Which leaves a profit after paying for buildings, and washing, &c., &c., - - $720,000

2. Estimate for manufacturing the fine short staple flax into fine linen. * * To manufacture 2,000,000 pounds, which will make 8,000,000 yards of linen, you must have in operation about 850 looms, at an expense of one thousand dollars each, - - - - - - - $850,000
Spinning 2,000,000 lbs. at 8 cts. per lb. 160,000
Weaving and putting up 8,000,000 yards, at 2 cents per yard, - - - 160,000
2,000,000 lbs. of fine staple flax at 50 cents per lb. - - - - - 1,000,000

$2,170,000

If we estimate this fine linen at fifty cents per yard, then the value of 8,000,000 yards will be - - - - - - $4,000,000
From which deduct as before, for buildings, machinery, stock and labor 2,170,000,

and a net profit is left of $1,830,000

Mr. Olcott, at his flax establishment at New Hope, works up at present, about three thousand tons of flax in the stem per year. This produces about 430 tons of fine short staple flax, ready for manufacture; from which it seems that it takes about 7 tons of stem to produce one ton of short staple flax. From Mr. S.'s letter we gather, that the lands in Penn. and N. Jersey, in the vicinity of New Hope, as an average crop, yield one ton of stem to the acre, for which Mr. Olcott pays at his factory twelve dollars a ton; and it is fair to conclude that the average yield of flax seed will be worth at least as much more from an acre, which will give the farmer 24 dollars per acre, as the avails of his flax crop, and this must be considered a good business. It is in the rich and beautiful prairies of the west, however, that we think the manufacture of flax will be carried to the greatest extent, and most profit. Should the flax noticed in our sketch of Mr. Parker's travels, as growing wild in the valleys beyond the Rocky Mountains, and being perennial like our grasses, be introduced into the western states, and succeed as we trust it may, it can then be mown like grass, and gathered year after year without a second sowing; and even the common flax cannot fail to yield a rich harvest to the industry of the fertile west.

From the Huntington Gazette.

RATS IN GRAIN.

How to prevent the ravages of rats in grain after it is housed, has been an inquiry of long standing. We can never exterminate them to such a degree as not to apprehend their incursions, for a horde of these troublesome visiters will often make their appearance when we least expect them. Instinct points the way where that provision best suited to their nature is found most plentiful. We have often found, when we went to thrash, our oats cut and cleaned by them, and the straw rendered unfit for any purpose whatever, except the subservient one of litter.

But every evil has a cure: and I have found "common elder" to be a common preventive, and have tested its properties as an anti-rat application. When the grain is to be packed away, I scatter a few of the young branches over every layer of bundles, being mindful to have them in greatest abundance on the edges of the pile. The drying of the twigs will give the grain an odor not relished by the vermin—which scent in no wise detracts from the quality of the straw for horses, as it makes no sort of difference with them. I have tried it successfully, a number of years, in wheat, oats and corn.

For the Farmers' Register.

GENUINE MORUS MULTICAULIS. NOT EXEMPT FROM THE DEPREDATIONS OF INSECTS.

"*October* 18*th*, 1838.

As Mr. Gideon B. Smith seems to be considered, by yourself and others, the best authority in regard to the multicaulis mulberry, there are two assertions in his communication in your last Register, which induce me to fear that I, who am one of the humbugged class, may have been buying the wrong sort. Mr. Smith says, "the leaves, when full grown on the vigorous wood, are 12 to 15 inches in length, and 10 to 13 wide." Now, after inspecting many hundred bushes of the kind I have purchased, which had all the appearance of vigorous growth, I have seen no leaf much, if any more than half that size. It is true, I did not apply my rule, but my eyes could not so far deceive me.

Again—Mr. Smith asserts, as "a remarkable fact, that all the species and varieties of mulberry tree are exempt from the depredations of all insects, except the silk-worm." He farther states, that, "during ten years that he had been a close and daily observer of the morus multicaulis particularly, he never saw an insect of any kind upon it." Since I know, from many years' observation, that he is mistaken in what he assumes to be a fact—at least so far as our native varieties, and the English mulberry, cultivated in our gardens, are concerned—I hope he is so in regard to the multicaulis, also. If he is not, then have I an additional reason to fear, that my purchase is not of the genuine kind: for, the few plants saved of a small trial made last spring, have their stems and many of their leaves now nearly covered with numerous small, greenish-colored bugs, that seem quite as much at home as if they were in their native domicil. We have been dosing them with soap-suds to kill or drive them off: but have not yet ascertained how the physic will work. It is probable, however, that it will be effectual; for these little depredators appear to be the same species which often infest our rose-bushes, and which are easily destroyed or driven away, either by soap-suds, or soot and water. This last mixture, by the way, is an excellent thing, if not made too strong, for accelerating the growth of all garden-vegetables, especially where the ground has not been fully manured. I remain,

Your friend and constant reader, J. M. G."

An editorial note, attached to the passage referred to above, stated another exception to the general rule which Mr. Smith had given as the result of his experience. That note drew from him the following passage of one of his private letters:

"I am much surprised at your note, [page 431, No. 7,] relative to the caterpillars devouring the multicaulis, and thank you for it. It is the first instance I ever heard of, and I fear it is the forerunner of a terrible calamity to the cause of the silk-culture in this country. I never heard of these insects touching any species of mulberry before; and as they never quit any kind of trees after they once begin upon them, I much fear they will extend their depredations to the mulberry generally; and if they do, it will be a sad drawback upon the business. But five years ago, our elms, [in Baltimore,] that had stood untouched by any insect for ages, were first observed to be infected by a small caterpillar; the insects increased every year, until in the last two years, our once stately and, as ornamental trees, entirely unequalled elms, have been entirely stripped of foliage, as though a deadly blast of fire had passed through them. Last year, the beautiful lindens were first visited by the same insect, and now we expect them also to share the fate of the elms."

We presume, that our friend, J. M. G., need not distrust the *genuine* character of his plants, merely because of the smaller size of the leaves. The sizes spoken of by Mr. Smith, were the largest, and not meant as usually found, on any but very luxuriant growth. No one who has once noticed the multicaulis, can mistake it for any other kind of mulberry tree; and, therefore, the person who furnished to our correspondent his original stock, could not have given a wrong kind, unless wilfully, and by designed deception.—Ed. Far. Reg.

INQUIRIES IN REGARD TO KEEPING SWEET POTATOES.

To the Editor of the Farmers' Register.

Can you inform us through your November No. how to preserve sweet potatoes through the winter? Should they be gathered before a single frost, or after one has fallen to kill the vines? I am inclined to think that the error is in suffering them to remain in the earth until a frost; and hence the difficulty of keeping them has arisen with us. Some of your correspondents in the lower districts, could inform you, as I have often seen large supplies from them in the spring, in a very perfect state. C. H. M.

SOAKING SEED CORN IN SALTPETRE WATER.

To the Editor of the Farmers' Register.

I am utterly astonished at the *simple fact*—"truly *simple*, in one sense of the word," stated in your last No. by Mr. Massey, of New York, as "one of the greatest discoveries of modern times" that corn soaked in a solution of saltpetre, and planted under equal circumstances, with this exception alone, produced 500 per cent. more than corn not so prepared.

A few years ago, for protection against the worm alone, I used this solution on my seed corn—alternating throughout, a large space of the field with, and without it, every twelve rows. The second year I also tried it for the same purpose, and *for no other*—the result was, in both, absolute futility in all respects. J. E. Muse.

Dorchester, Md.

[Our comments on this remarkable "*fact,*" were given at p. 434 of the succeeding number, to which the reader is referred.—Ed. Far. Reg.]

From the Maine Farmer.

PIG TROUGH.

A writer in the Genesee Farmer, a few years ago, described a method of making this article, which we copied into the Maine Farmer, and which we have also practised, and find to be a great improvement.

It is simply this. Take two pieces of board or plank of the length that you wish your trough; put two of their edges together at right angles, thus V, and nail them strong. Then take two pieces something longer than the trough is wide and nail upon the ends. Then take some clay mortar and fill up the chinks to prevent its leaking, and it is done. The food settles down in the angle at the bottom of the trough, and the pig will *fay* his sharp under jaw into it completely, while the long ends prevent its being upset so easily as the old kind. Any body who can saw a board off, and drive a nail, can make one. If you have no trough for your pig, just try your hand at making one on this plan.

From the Cultivator.

SUBSTITUTE FOR SPAYING. ANOTHER WITNESS.

Ivanhoe, Campbell Co. Aug. 18, 1838.

Dear Sir—I have been for some time an attentive reader of your valuable paper; from each page information is to be gained. In your last number, you instruct us how to perform the operation of caponing cocks, before which I knew not. And it is the above which prompts me to give you the following information:

The old method of gelding sows is not only very cruel, but quite disagreeable to the operator, as well as dangerous to fat animals. Now, sir, the modus operandi in this neighborhood as practised by myself lately, but much longer by others, is simply this: For convenience use a common goose quill as a tube, cutting off smoothly the small end, the other shaped as for a tooth-pick, to be used as a handle; then pass the small end down the vagina two inches or more, (according to the size of the animal,) through which drop six or seven shot, say No. 3, and your work is complete. Nothing can be more simple, innocent, or efficacious.

Should you think the above worth making known, you can publish it.

Very respectfully, your ob't. serv't.

Edward B. Withers.

From the Tennessee Farmer.

LOIN DISTEMPER IN HOGS.

By this I mean the loss of the strength of the hinder parts. One of my best hogs was found the other day unable to walk, from falling behind; and as I never saved one thus diseased, I gave him up for lost. I, however, separated him from the herd, and concluded I would nurse him until he might die, as is my practice—being opposed to killing any of my animals that may chance to sicken or get wounded.

Now, as the treatment, or something else, has relieved him, I annex it. I poured warm tar upon his loin; when this dried, I repeated it—pulling out the hair adjacent. Simultaneously with this, I mixed one tea-spoonful of arsenic in corn meal dough, which he ate freely. He is now on his feet and doing well. Whether my hog recovered in consequence of the treatment, or in spite of it, I cannot tell; but one thing I know—all that had it before died, and this one lives. I do not wish to get the people to poisoning their hogs with arsenic; but as it is a gone case any how, those who may venture upon the practice, I hope may have the same good luck.

Parvus Agricola.

July 28, 1838.

From the Farmville Journal.

THE MORUS MULTICAULIS.

As many persons in your vicinity are interested in the culture of the mulberry I send you a few remarks upon an article in the last Farmers' Register. Mr. Ruffin there advises farmers who have any idea of going into the raising of silk "not to buy them (the Chinese mulberry) or at least very few of them at the exorbitant prices, which the always easily gulled public have heretofore paid, and which are now threatened to be advanced." In a subsequent editorial, advising present holders not to sell, he says, "and therefore at half a cent or even a quarter cent the bud, the stock of 1839 will yield a much greater sum, than the present growing stock at two cents the bud or 25 or 30 cents the rooted plant." We will not dwell on the slight inconsistency of advising purchasers not buy and sellers not to sell, as our object is simply to examine the question whether it is for the interest of those who are intending to engage in the silk business to purchase the morus multicaulis now at present prices, or to purchase two years hence at greatly reduced prices. Mr. Ruffin says, that buds are regularly and readily sold at two dollars per hundred, and that he is preparing to come into the market with trees and cuttings as soon as he can furnish them at one-fourth the present price. We infer, therefore, that he considers one-fourth the present price, or half a cent a bud, a fair price, or the probable price a year or two to come, when the mania has subsided. But to put our calculations out of the reach of cavil, we will suppose the price of multicaulis buds two years hence to be one-eighth of a cent each, only one-sixteenth of the present price, and we think we can demonstrate from Mr. Ruffin's own data, that a person who intends engaging in the business, had better give 100 cents a bud *now* than one-eighth of a cent for a bud two years hence. We take Mr. Ruffin's own data. "Every single bud planted next spring and well taken care of, will produce from 10 to 70 buds, say not less than 30 on an average." One bud then set out in the spring of 1839 will produce 30 in the fall, which set out again in the spring of 1840 will produce in the fall 900 buds, and the original bud will produce the second year 100 buds, making in the fall of 1840 1000 buds, besides 31 roots. The roots will be a fair compensation for labor, rent of land and interest. The 1000 buds at one-eighth of a cent would be one dollar and twenty-five cents. That is, a bud for which 2 cents is now thought an exorbitant price, will in two years produce buds worth $1,25 at one-eighth of a cent each. It will be seen then that an individual, who intends engaging in the business at all may as well give $1,25 *now* for a bud as one-eighth of a cent for a bud two years hence, according to Mr. Ruffin's data. We think, however, his calculations are rather too high for ordinary country cultivation. Twenty buds for one will be found nearer the truth in most cases, though we have no doubt with great care, 30 may be realized. One bud would then produce 20 the first fall, the 20 would produce 400 the second fall. Add 100 buds for the produce of the first bud the second year, and we should have 500 buds the second fall. At one-eighth of a cent, 500 buds would bring 65½ cents. The roots paying for cultivation, &c. According to this, a person had better give 50 cents now for a single cutting than one-eighth of a cent in 1840—besides the pleasure of a comfortable hobby to ride for two seasons. We offer these calculations for the benefit of those who have trees to sell as well as those who wish to buy, and have shown, we think, that if cuttings are worth one-eighth of a cent in the fall of 1840, present owners had better keep their cuttings than to sell them for 10, 20, 30, or even 50 cents a bud, to say nothing of 2 cents, and that purchasers would, of course, do better to buy now at 20 times the present exorbitant price, than at one-eighth of a cent in the fall of 1840.

MULTICAULIS.

[We are always willing to receive correction, and submit to censure properly applied, whenever our editorial errors require either; and the republication of the foregoing piece, from another print, is evidence that we do not, in this case, wish to conceal the censure, or keep out of sight the alleged inconsistency, by which it has been elicited. But we do not admit the inconsistency charged; nor would our censor have made the charge, if he had more carefully read, and correctly quoted our expressions. The advice in the first piece, "not to buy at the then exorbitant prices," was limited in its bearing to the purchasing of *plants in large quantities*. It was not meant for speculators, but for farmers who desired to commence the silk business; and the advice was founded upon estimates then submitted, and very similar to those made (and very correctly made,) by our censor, and both of which show clearly, that a very few plants bought now, would, in a few years, suffice to furnish an abundant stock of trees. The question, then, for those having no view to the selling of trees, was this: "Is it better to buy 2000 trees now, or only 50 or 100, and be but a year later, in obtaining a stock equally large?" If most buyers had decided upon the latter course, it would have moderated the violence of the speculating fever; and if purchasers generally were to choose the former and quicker course, it is manifest that the bubble of speculation would be distended to a hundred-fold its then, or even its present magnitude, and that market prices would be as much advanced above the intrinsic value of the plants—great as that intrinsic value certainly is. Our remarks then, and our course since, were designed and calculated to repress the enormous excess, the madness of speculation, as much as to urge proper attention to mulberry and silk-culture. As we first advised intended culturists not to buy *many* at exorbitant prices, so six weeks after, (for that time elapsed between the printing of the two pieces, as was stated and explained,) when the prices were still more exorbitant, we advised the cultivators "not to sell any *to speculators*, lower than at the highest [existing] prices." This is very different from advising simply those who wanted, "not to buy," and those who held, "not to sell," alone and without limitation, with which inconsistency we are charged above. The fact was, that northern speculators had been sending all over Virginia, and, before the holders were aware of the great advance of prices, had bought up many nurseries at less even than the intrinsic value, and at less than a sixth of what they would now sell for. One individual, as we are informed, has in this way made $150,000, within the last few months. Our warning, though late, was in time to save thousands of dollars to some of the cultivators.

But though we deny the inconsistency charged above, we are far from denying great changes of opinion on this subject, within less time than elapsed between the writing of these two pieces. Indeed, if any man has thought precisely alike, made similar calculations of profit and loss, and would have pursued the same course, at any two periods six weeks apart, during the time of the rapid growth of this mulberry mania, we readily admit that he has far more wisdom, and especially more foresight, than we can boast of possessing. No man could have foreseen the extent and rapid growth of this mania, nor can we pretend to do so at this later time.

Our former intimation that we were preparing to come into the mulberry market when we could contract at one-fourth of current prices, was not meant otherwise than to express the certainty of the then high prices being short-lived. We certainly did not mean to propose that any person should wait to obtain his stock from us, on such terms. But the intimation, then given in joke, we are very ready to execute in earnest, by now contracting to deliver plants next autumn, at one-fourth of the prices current at the time of making the contract. Nor is this offer made at any risk; for where the crop is as sure, and the growth and increase as great, as in lower Virginia, any one may safely buy stock at the highest prices yet heard of, if he can sell the product, on previous contract, at one-fourth of that price.—Ed. Far. Reg.

WELL SPRINGS.

To the Editor of the American Farmer.

Newbury, S. C., July 5, 1824.

Sir—Permit me to communicate to you a new method of digging wells, which in a hilly country makes them, in my opinion, superior to springs.

The method occurred to me some years ago, and I have often spoken of it as practicable, but I never heard of its being reduced to practice until lately. Mr. John Rhoden, of Chester, I am informed has in the course of the last year made the attempt, and completely succeeded.

Mr. Rhoden had a well on the side of a steep hill, the cleaning and repairing of which had cost him much trouble and expense, to little purpose. At length it occurred to him that if he could make a horizontal opening into it from the side of the hill, on a level with the vein, that he might thus be enabled to procure a running stream from the well, such as is found at springs, and gain an easy access to it, for the purpose of cleaning it out whenever it might become necessary. When the work was set about, it was accomplished in a few days, and he has now, out of his well, an excellent spring; easy to be cleaned out, with a very convenient milk-house.

The plan which had previously suggested itself to me, and which I still think is even superior to Mr. Rhoden's, is this—select a steep hill, (whose declivity should be, if possible, 45 degrees,) and dig down, opening out as you go in the form of a ditch, from the inner wall of the well, to the side of the hill, and wheeling off the dirt in a barrow, until you come to the vein. Or make, in the first place, a horizontal opening, such as Mr. Rhoden did, into the vein, instead of digging perpendicularly as is usual.

The first method proposed may at first view appear to involve a great deal of labor; but I am certain that on a hill declining at the rate of 45, or even 50 or 60 degrees, a well can be sooner dug, with less labor, with greater facilities for blowing rock, greater security against damp, and more certainty of finding a vein than a common well.

It can be sooner dug and with less labour, for in the first place the dirt to be removed is but about three times as great, as will be procured by only making a diagram of the hill; and in the second place, instead of having to haul up the dirt by a windlass, at the great risk of the well digger, and with much labor and loss of time, it can be wheeled off along the level of the ditch, by a common hand as fast as it is dug.

As to this method affording greater facilities for blowing rocks and greater security against noxious damps, than the common method; this is so apparent as to require no proof.

It is attended with a greater certainty of finding water, because in the common method unless a vein is found within the diameter of your well, you may continue to dig without success, although numerous veins may be running within a small distance of you. But in the method I propose you will have a chance for every vein which runs from the outside of the hill to the inside of the well, for your ditch must traverse the whole of them.

I believe the second method I have proposed has nearly as many advantages as the first, and some others; but these must suggest themselves at the first view, and require no elucidation.

An excellent milk-house may be easily made in the excavation, under either method.

I will not dilate upon the advantages of this method of digging wells. Allow me only to reiterate the superior facilities it affords for keeping them in order.

Many tracts of land, whereon there are no springs, lose half their value; because few would be willing to settle them, and undergo the trouble and inconvenience of watering their whole stock from a well. But my method (or rather Mr. Rhoden's) would afford a running stream from the well for that purpose.

Yours, most respectfully,

Job Johnston.

From the Penny Magazine.

CHANGE OF THE WATER LEVEL IN THE BALTIC.

In Mr. Greenough's address to the Geological Society, as reported in the 'Philosophical Magazine,' it is stated that, as early as the time of Swedenberg, who wrote in 1715, it was observed that the level of the Baltic and German Ocean was on the decline. About the middle of the last century an animated and long-continued discussion took place in Sweden, first as to the cause of this phenomenon, and then as to its reality. Hellant of Tornea, who had been assured of the fact by his father, an old boatman, and who afterwards witnessed it himself, bequeathed all he had to the Academy of Sciences, on condition that they should proceed with the investigation; the sum was small, but the bequest answered the purpose. Some of the members of the Academy made marks on exposed cliffs and in sheltered bays, recording the day on which the marks were made, and their then height above the water. The Baltic affords great facility to those who conduct such experiments, as there is no tide, nor any other circumstance to affect its level, except unequal pressure of the atmosphere on its surface and on that of the ocean; this produces a variation, which is curiously exemplified at the Lake Malar, near Stockholm. As the barometer rises or falls, the Baltic will flow into the lake or the lake into the Baltic. The variation resulting from the inequality of atmospheric pressure, however, is trifling. In sheltered spots mosses and lichens grow down to the water's edge, and thus form a natural register of its level. Upon this line of vegetation marks were fixed, which now stand in many places two feet above the level of the water. In the years 1820-21, Bruncrona visited the old marks, measured the height of each above the line of vegetation, fixed new marks, and made a report to the Academy. With this report has been published an Appendix by Halestrom, containing an account of measurements made by himself and others along the coast of Bothnia. From these documents it would appear—1st, that along the whole coast of the Baltic the water is lower in respect to the land than it used to be; 2dly, that the amount of variation is not uniform. Hence it follows, that either the sea and land have both undergone a change of level, or the land only; a change of level in the sea only will not explain the phenomenon. A quarter of a century has now elapsed since Mr. Von Buch declared his conviction that the surface of Sweden was slowly rising all the way from Frederickshall to Abo, and added, that the rise might probably extend into Russia. Of the truth of that doctrine, the presumption is so strong, as to demand that similar experiments and observations should be instituted and continued for a series of years in other countries, with a view to determine whether any change of level is slowly taking place in those also. The British Association for the Advancement of Science has already obeyed the call. A committee has been appointed to procure satisfactory data to determine the question as far as relates to the coasts of Great Britain and Ireland; and it is to be hoped that similar investigations will also be set on foot along the coasts of France and Italy, and eventually be extended to many of our colonial possessions.

From the Southern Agriculturist.

CAUSE, AND PREVENTION OF FEVERS.

September 28th, 1838.

Mr. Editor.--The many and various observations made upon the change of climate, increase of sickness, and the annual abandonment of our plantations, you are no doubt as familiar with as I am. Time was, when people could remain on, and enjoy their estates all the year round, and with proper management, I think we may in a few years do it again. A writer in your journal, (I believe it was) some time ago, ascribed the comparative frequency of freshets to clearing of the land, and justly in my opinion—but he overlooked a more important consequence, the effect upon the health of the country. I am of opinion, a little reflection will show the change of climate is identical, and has kept pace with, that in the surface of the earth. While in possession of the aborigines, our whole country was comparatively pure and healthy, and Dr. Rush states, that so late as 1782, "some country people of Bedford county, Pennsylvania, travelled twenty miles to see whether it were possible for a German girl, who labored under an intermittent, to be hot and cold at the same time." In former times, fevers were confined to the banks of rivers, creeks and ponds, but the clearings have opened just so many passages for swamp or marsh effluvia, and we find fevers prevailing in the interior, where they were formerly unknown. This will always be the consequence of clearing, without cultivating the ground. While opening the country makes it sickly, as I have already mentioned, *cultivation*, that is, draining swamps, destroying weeds, burning brush, and exhaling the superfluous moisture of the earth, by growing frequent crops of grain, and vegetables of all kinds, renders it healthy. There are other causes of sickness, which never can be entirely overcome, because man has no control over the seasons; the healthiness or unhealthines of a country, depending much on the cold or heat, the dryness or wetness of particular periods. While rivers and creeks, are, from uniformity of seasons, confined to steady bounds, there will be little or no exhalation of febrile maismata from their shores. But when swelled beyond their natural heights by a wet winter and spring, they fall, and leave a very extensive surface of ground completely saturated with water, exposed to the action of the sun, and of course to the generation of, and exhalation of febrile miasmata. A country is always free from fevers during the overflow of its rivers—but subject to them after subsidence of the waters. It may be remarked, that a wet season is often healthy in the low, while it is sickly in the hill country, and I think the reason obvious. In the former, the rains cover all the moist ground entirely, while in the latter, they fall only in a sufficient quantity, to produce those degrees of moisture which favor febrile exhalations. The rains which fall in summer, are rendered harmless only by covering the whole surface of the ground. Frequent, and heavy rains after the middle of September, are favorable to health, diluting, and thus destroying as they do, the febrile miasmata that were produced by the heat, and moisture of the preceding summer. Man can do but little towards preventing the evil effects of drought upon the health of a country, but he can do much to avoid, or mitigate that which results from excess of moisture; by good culture of the earth, and draining the low grounds. I beg leave to suggest a few hints for obviating and preventing fevers. For this purpose, I would recommend that all trees between settlements, and the quarters or points, from which the summer and autumnal winds blow, be suffered to remain, and become as dense as possible, particularly if a river, creek, pond, or moist expanse of country be to windward of them. If the settlements have no forest defence, cultivate one of the trees which will soonest attain their growth, and not too far from the house or settlement. The trees about each house, should not be so close as to prevent a due evaporation of redundant moisture from the ground. If a reservoir or pond be near, allow the growth in it, and on its borders to continue, and if necessary, set around it additional trees. Trees to leeward of rivers, creeks, and ponds, can never be too numerous, or thick. Around a pond, they act in a small degree, mechanically. By sheltering it from the action of the sun, they lessen the exhalation, as well as obstruct the passage of the vapors that are raised, to the adjacent parts. But trees act likewise chemically. It has been demonstrated, that they absorb unhealthy air, and discharge it in a highly purified state, in the form of diphlogisticated air. The willow tree has been proved to purify the air more rapidly than any other. The rapidity of its growth, its early verdure, and the late fall of its leaf, all seem to designate it, as highly proper for this purpose. A second method of preventing fevers, is to let the cultivation always keep pace with the clearing of our lands. Nature has, in this instance, connected our duty, interest, and health together. Let every spot covered with moisture, from which the wood has been cut, be carefully drained, and then ploughed and sowed with grass-seed; let weeds of all kinds be destroyed, and let the waters be so directed as to prevent their stagnating in any part of their course. These are the two principal means of extirpating fevers from our country; but as they are slow in their operation, I will suggest a few preventives, till the above remedies can take effect.

Whether the matter which produces fevers, be of an organic or inorganic nature, I do not pretend to determine: but it is certain that fire, or the smoke or heat from fire, destroys the effect of swamp or marsh miasmata upon the human body; from this cause, we find cities more healthy than country places, and commonly, the centre of cities more healthy than their suburbs, in the sickly months. Where it can be done, I would advise large fires to be made every evening, between the spots from whence the exhalations are derived and the house, as near the latter as is safe, and not troublesome. This practice should be continued till the appearance of two or three frosts, for frosts, as well as heavy autumnal rains, never fail to put a stop to the progress of intermittents. During the sickly season, fires should be likewise kept in every room in the dwelling-house, even when the heat of the weather makes it necessary to have the doors and windows open.

Let me advise all in sickly situations to prefer woollen and cotton clothes, to linen in the summer and autumnal months. Great confidence may be placed in woollen and cotton clothes, in raw, wet weather, as preventives of fever, but most in woollen.

The diet in the sickly months should be generous. Wine and beer should be the drinks of this season, instead of spirits and water. Fruits and vegetables are not unwholesome; but as the season of the year produces languor and weakness, a larger quantity of animal food than usual, is best calculated to oppose fevers. Salted meat, for this reason, is preferable to fresh meat. Food of all kinds, eaten during the sickly months, should be well seasoned.

The evening air should be avoided as much as possible. Before breathing the morning air, the body should be fortified with a little solid aliment, or a glass of bitters. These bitters should be made of centaury, wormwood, camomile, or the bark of the willow or dog-wood tree, infused in water. Bitters made with spirits, or even wine, cannot be taken in a sufficient quantity to do service, without producing intoxication, or the deadly habit of loving and drinking spirituous liquors.

The person should be bathed or washed frequently, and those who have not access to the sea, will find that adding salt to water, renders it powerful in preventing diseases. Preserve cleanliness in every species of apparel. Offal matters, should be removed from the neighborhood of dwellings. The excrements of domestic animals may be excepted, for nature has kindly prevented any inconvenience from them. More than this, she has endowed their dung with a power of destroying the effects of swamp, or marsh exhalations, and of preventing fevers. The cottagers of Europe, who live under the same roof, and even under the same roof with their cattle, are almost always healthy. These counsellings, are founded on practice and observation. Yours, respectfully,

A Patron.

From the American Farmer.

AN EXPEDITIOUS METHOD OF MOVING HAY.

Culpepper county, Va. July 7th, 1838.

Mr. Skinner.—In the last number of your American Farmer one of your correspondents has described an expeditious mode of drawing hay to stacks, in use in Hardy county, Virginia. The same method was formerly adopted by some farmers in this county; but that now most generally used here, seems to be so much more easy and expeditious, that perhaps a description of the mode may deserve a place in your useful paper. So slow is the progress of even small improvements in agriculture, and labor-saving operations, that it is probable many of your readers have never seen this practised.

The hay being cocked, and the stacking about to be commenced, a hickory pole ten or twelve feet long, is procured, and the knots all well trimmed off. The larger end of the pole should have a hole bored in it, to admit a clivis pin, and to which the swingle tree of the horses in gear, is to be attached by means of the clivis. The smaller end of the pole should be brought to a smooth point, so as to admit its being run under the cocks of hay, and a leading line should be attached to the large end, about where the clivis goes through. A boy, holding this pole in one hand, thus fixed to the horse, and guiding the horse with the other, comes to the cock of hay. The pole is immediately disengaged, by taking out the clivis pin—the boy then runs the pole under the cock, till the sharp end has passed a little distance, say two or three feet on the other side: he then throws the line attached to the large end of the pole, across the top of the cock, and by a slight bow knot fastens it to the pole on the other side, taking care to have the rope placed exactly over the middle of the cock—the horse is then attached to the pole by fixing in the clivis; just as the horse sets off, it is necessary to take hold of the pole just behind the place where the rope is tied to it, to prevent its slipping, until the cock moves, when there is no longer any danger. After getting with the cock to the stack, without its being necessary even for the horse to stop, the knot is slipped, and the horse goes on with the pole, leaving the cock in nearly as good a situation as when it was first touched. There is less work for the hand-rake after the cocks thus drawn, than in the mode described by your correspondent, and the draft is much less. One horse will draw, with ease, cocks of three hundred weight, and as fast as two can pitch up to one stacker. The draft is less, in consequence of the hay next the horse being somewhat raised from the ground, and the friction against the ground greatly reduced.

Your constant reader,

A Young Farmer.

RABBIT, CUNICULIS, IN ZOOLOGY.

Interesting and authentic account of some of its curious habits.

[This little animal affords a remarkable instance in the variety of its colors, of the effect of *domestication.* In its wild state, it is uniformly of a brown cast; when tamed, its color ranges through every shade, from raven black, to the whiteness of mountain snow.

They begin to breed at a year old, sometimes sooner; and multiply five, six and seven times a year, having from four to eight at a litter. thus increasing so rapidly, that to say that "she breeds like a rabbit," is to express, proverbially, the idea of great fecundity.

When the buck approaches the doe, he first beats and stamps very hard with his feet, and after embracing her, falls backwards and lies motionless, as it were in a trance; in this state he may be readily taken, but he soon recovers from it.

The extent of rabbit warrens in England, where, in some districts, many hundred acres in a body are appropriated to the raising of rabbits for sale, would appear surprising to those who had never adverted to the subject. As inquiries have been made by correspondents relative to the proper construction of rabbit warrens, and their management, we give sketches from English authorities, which follow the interesting and curious remarks of Mr. Hardin, on the habits of that animal.—[Ed. Am. Far.

To the Editor of the American Farmer.

Near Shelbyville, Ky., 6th March, 1824.

Dear Sir—When we become subscribers to the American Farmer, I consider it a tacit admission, that we belong to the same social compact, and that our general experience is a kind of common property, upon which you have a right to draw whenever you may think it beneficial to its members.

And should any speculative theory appear in your columns, it is then either of us (whose experience conflicts with such theory) is substantially called on to contribute his mite. Under this impression (and not from a spirit of contradiction I assure you, sir,) do I give you some of the habits of the rabbit; which at once overturns the theory of Doctor Macaulay, in your 40th No. of Vol. 5, wherein he concludes that "the male rabbit destroys the young, for the sole purpose of enticing "the embraces of the mother."

While I resided in Frankfort, I procured the white, the black, the gray, and the blue rabbits, and after a few years, some of the offspring turned out entirely yellow, or copperas-colored. As they were a rarity with us, I was not inattentive to their habits, and all that I relate of them is from *personal* observation. From the entire level of my lot, there was no bank, or hill side for them to burrow in, of course their cells were frequently deluged by rains, and their young drowned; to protect them from this casualty, I frequently dug down to the extremity of the hole, and fixed an inverted box over the place, so that the young might be placed in the box during hard rains. I castrated most of the males when young, so that at all seasons of the year, they were fit for table use: to distinguish the stags, I always split one of their ears, so that I might not be mistaken in catching them. Although I have never had a hundred at a time, yet I have had upwards of ninety. Like all domestic animals, they may be taught to come to food by any particular sound—I chose a a peculiar kind of whistle between the hands, and by shelling corn around me, could take by the ears any one of them without disturbing the rest. I would advise a southern hill side for a warren, and the only way I could prevent their burrowing out, was to place a row of bricks, laying them flat with their ends against the wall, and sunk only level with the surface, so as to form a nine inch pavement all around the warren; the rabbit will commence immediately at the wall to burrow out, the brick pavement prevents it. Some few days before parturition, the female burrows her hole from four to six or eight feet, and carries grass, hay, or whatever litter is most convenient, and forms her bed; she then closes the mouth of the hole by returning to it part of the dirt, and pressing it down with her fore feet, so as to leave no appearance of the hole. Just before parturition, she opens the hole and lines this bed with her own fur, and immediately after parturition she comes out, securely covers the hole, and runs in search of the buck, and *in less than ten minutes receives a new impregnation.* She does not visit her young but once in twenty-four hours, unless it is in the night, which I do not believe. I have seen them open the hole, go in, and uniformly *in two minutes by the watch* return, close the hole securely and leave it. I have then, by removing the box and examining the young, found them quite full. In about three weeks she leaves a small opening at the mouth of the hole, the young then occasionally come out, in a few days more she closes the hole when then are out, and when they are thirty days old she has a new litter. When I have wanted to use the young for broiling, I have at the time of parturition, and for some time after, kept the mother secluded from the buck, so that she might suckle them a few weeks longer. If these statements be true, Doctor Macaulay's supposition is without foundation. So much for facts, take my conclusions for what they are worth—my own conclusion has been, and still is, that at parturition, the mother leaves with the bed of young exactly the kind of odor, which accompanies her to the buck, after the first caresses she plays the coquet and hides from him; in his search for her, if he comes to the bed of young, (to which he is guided by the scent, unless they are very secure) he scratches them to pieces, not from motives of destruction to them, but to drive the doe (which he believes there hid) from her lurking place.

This too may be speculative theory, and I can have no objection to its being put down by one more plausible, tested by experience, and carrying with it more of the rational.

Respectfully, yours,

Mark Hardin.

P. S. You may think strange that I have gone so much into detail. This is my apology—long since some of your subscribers called for information respecting warrens, and I have never seen an answer to it, of course if he is not better supplied, what I have said is intended for his benefit.

M. H.

"The food of the tame rabbits may be cole wort and cabbage leaves, carrots, parsnips, apple rinds, green corn, and vetches, in the time of the year; also vine leaves, grass, fruits, oats, and oatmeal, milk-thistles, sow-thistles, and the like; but with these moist foods they must always have a proportionable quantity of the dry foods, as hay, bread, oats, bran, and the like, otherwise they will grow pot-bellied and die. Bran and grains mixed together have been also found to be very good food. In winter they will eat hay, oats, and chaff; and these may be given three times a day, but when they eat green things, it must be observed, that they are not to drink at all, for it would throw them into a dropsy. At all other times, a very little drink serves their turn, but that must always be fresh."

"Rabbits are subject to two principal infirmities. First, the rot, which is caused by the giving them too large a quantity of greens, or from the giving them fresh-gathered, with the dew or rain hanging in drops upon them. It is excess of moisture that always causes this disease; the greens, therefore, are always to be given dry, and a sufficient quantity of hay, or other dry food, intermixed with them to take up the abundant moisture of their juices. On this account, the very best food that can be given them is the shortest and sweetest hay that can be got, of which one load will serve two hundred couples a year; and out of this stock two hundred may be eat in the family, two hundred sold to the markets, and a sufficient number kept in case of accidents.

"The other general disease of these creatures is a sort of madness: this may be known by their wallowing and tumbling about with their heels upwards, and hopping in an odd manner into their boxes. This distemper is supposed to be owing to the rankness of their feeding; and the general cure is the keeping them low, and giving them the prickly herb, called *tare-thistle*, to eat."

"The general computation of males and females is, that one buck rabbit will serve for nine does; some allow ten to one buck; but those who go beyond this always suffer for it in their breed."

[The estimate of the warren, on the estate of Thorseway, in England, of 1700 acres, as given by the tenant, Mr. Holgate, with the silver sort of rabbits is this:]

	£.	s.	d.
"Labor, three regular warreners, with extra assistants at killing,	85	0	0
Fences, - - - -	42	10	0
Winter food, - - - -	42	10	0
Nets, traps, &c. &c. - -	14	3	4
Delivery, - - - -	21	5	0
Rent is said to be 7*s*. an acre,	595	0	0
The capital employed is the above with the addition of stock paid for: suppose this as stated about three couple an acre at 2*s*. 4*d*.	595	0	0
	1395	8	4
Interest on that sum one year at 5 *per cent.*	69	15	5
	1465	3	9

Annual Account.

	£.	s.	d.
Expenses as above, - -	800	8	4
Interest, - - - -	69	15	5
	870	3	9
Produce 10,000 couple, at 2*s*. 4*d*.	1166	13	4
Expenses, - - - -	870	3	9
Profit, - - - -	296	9	7

Or about 22*l*. *per cent.* (the 5 *per cent.* included) on capital employed. This the writer observes is very great, reckoned on the capital, but small reckoned by rent, as it amounts to only half a rent. But suppose the gross produce of 1500, which he takes to be nearer the fact; then the account will stand thus:

	£.	s.	d.
Produce, - - - -	1500	0	0
Expenses, - - - -	870	3	9
Profit, - - - -	629	16	3

or 45 *per cent.* on the capital."

"It is remarked, that the author of the Treatise on Agriculture and Gardening, has bred these animals with much success and ornamental effect in a small artificial warren, in a lawn in the garden, made in the following manner.

"Pare off the turf of a circle, about forty feet diameter, and lay it on the outside; then dig a ditch within this circle, the outside perpendicular, the inner sloping, and throw earth sufficient into the middle to form a little hill, two or three feet higher than the level of the lawn; the rest must be carried away. Then lay down the turf on the hill, and beat it well to settle. The ditch at bottom should be about three feet wide, and three and a half deep, with two or three drains at the bottom, covered with an iron grate, or a stone with holes, to carry off the hasty rains, in order to keep the rabbits dry. In the outside bank should be six alcoves, the sides and top supported, either by boards or brick work, to give the rabbits their dry food in; by their different situations, some will always be dry; six boxes, or old tea-chests, let into the bank, will do very well. If the ground be very light, the outside circle should have a wall built round it, or some stakes driven into the ground, and boards or hurdles nailed to them, within a foot of the bottom, to prevent the bank from falling in. The entrance must be either by a board to turn occasionally across the ditch, or by a ladder. The turf being settled, and the grass beginning to grow, turn in the rabbits, and they will immediately go to work to make themselves burrows in the sides, and in the hill. By way of inducing them rather to build in the sides, to keep the turf the nearer, make a score of holes about a foot deep, and they will finish them to their own mind; and if there be a brick-wall round it, it should be built on pillars, with an arch from each, to leave a vacancy for a burrow." But there is, he says, another way that may be practised, which is, "to dig the ditch only about two feet deep, which will yield about earth enough to make the hill; put some pales, about a foot high, on the outside, for that will be a sufficient height to keep the rabbits in. Feed them as other tame rabbits are fed; and in wet weather sprinkle saw dust at the bottom, by which means the quantity of manure will be increased; once a week is often enough to take it way: the quantity will be surprising, nor will the smell be in the least offensive, even though it be quite close to the house. In a very large lawn, two or three of these hills, with the rabbits feeding on the tops, will not be unpleasing objects. If the bucks happen to be mischievous in killing the young ones, they must be chained in an alcove; or else have their liberty as in a warren. After a great snow they will want some assistance early next morning; because the ditch will be nearly filled, and perhaps the alcove, where the hay is, will be blocked up."

He adds, that "it is a great improvement to castrate the young bucks, and keep them till they are full grown, before you kill them; the flesh will be amazingly finer, whiter, and tenderer. But then it will be best to take them away, and keep them in another warren, lest they should be too numerous, and disturb the breeding does; or else have a few hutches in the alcove to fatten them in."

SEASON AND STATE OF CROPS IN HALIFAX.

To the Editor of the Farmers' Register.

Halifax, Va., Sept. 15th, 1838.

Since I wrote you, about the 12th of August, the drought has continued to prevail almost without a shower. We have not had rain enough to more than moisten the lightest land to the depth of 1 or 1½ inches since the 6th day of July. The effect of so long continued dry and such excessive hot weather as we have had, can perhaps be better imagined than described. The corn crop which, up to the 20th or 25th July, was the most promising I ever recollect to have seen in this county, is now certainly the worst, much the worst I ever saw any where. Many fields will yield but little if any more than the seed, and that of very inferior quality. In addition to the destructive effect of heat and drought, the chinch bug has fallen aboard of many fields and parts of fields, and nearly or quite finished the work of destruction. Many of our farmers seemed never to find that the the bug was injuring their corn until they commenced gathering the few blades that were left worth gathering. I am satisfied from what I have seen and heard from good authority, that there cannot be but little, if any more than ⅓ of a corn crop made in this county. Pittsylvania and Campbell certainly not more than half a crop.

Tobacco is, if possible, less promising than corn. We are generally, at this season, busily engaged, all hands cutting and curing tobacco, now we are almost without employment of any kind on the crop. Until yesterday, I had not seen a single plant of tobacco cut this season, and much the larger part will not be worth cutting at all, should we have early killing frost. We once hoped, on finding our corn crops failing, that we should certainly have rain in time to sow and raise a great many turnips to help us through the winter with our stock, that hope seems now almost gone. I have sowed, and know many of my neighbours that have, but what few came up, has all or very near all perished for want of moisture; in fact, I don't think *I* have one living. A PLANTER.

[The foregoing letter, though dated September 15th, was post-marked the 30th, and of course arrived after the last No. had been printed and issued. It is necessary that communications, to be inserted, should be in hand by the 25th of the month, at latest.]

SEASON AND STATE OF CROPS IN OCTOBER.

We have heard very little from correspondents, in October, of the state of crops, and therefore infer that the corn crop is no where *worse* than appeared from our last month's report, and that in the locations not there mentioned, it is *better*. On the fine Gloucester low-grounds there is a good crop made; and in King William, not a bad one. We hope that much of the corn-producing part of lower Virginia has so far escaped the general calamity, as to be able to furnish some surplus corn for the wants of the other parts of the country.

Since the last week in September, the rains have been superabundant, so as to make bad and slow work in sowing wheat. This, added to the small amount of fallow land prepared, (on account of the drought, in August and September,) will affect injuriously the product of the next crop.

After very early frost, in September, which hurt some tobacco in the upper counties, and which so alarmed many planters as to induce them to cut their crops too green, there has followed, and still continues, an unusual length of mild weather, in which every green crop could continue to improve in growth, or in maturity.

October 29, 1838.

PRINCEANA.

To the Editor of the Farmer's Register.

In several newspapers I have observed the following advertisement, of which I request a republication in the Farmers' Register, together with my comments thereon:

"*Competition.*—Much has been said lately about the superior growth of the morus multicaulis in Virginia, and the greater maturity of the wood for cuttings, &c. We now offer to exhibit one, two, three or more thousands of our trees with any plantation of one year's growth of the same kind existing in Maryland or Virginia; and if ours are not superior in the growth of the wood to any other parcel of similar extent, we will pay to the owner of the other parcel one thousand dollars, or one thousand of the trees, he agreeing to a similar forfeit if the reverse is the case. The truth is, their growth is as great in Connecticut and Rhode Island as in Virginia, and trees of two and three years old, are here found to be as hardy as an apple tree. WM. PRINCE & SONS, *Flushing, New York.*"

It is an old and approved saying, that "a wager is a fool's argument." But though Mr. Prince is no fool—and, on the contrary, no man is *sharper* in his vocation of selling plants, *to the best advantage*, still the saying is not the less true, applicable in a different sense; for though the wager is not offered *by* one, it is meant for the use *of fools*, or to make fools and dupes by its operation. This seeming offer to bet on the *superior growth* of his multicaulis trees, is simply a specimen of the "puff boastful;" a mere trick of Mr. Prince's trade, which he will abandon just as soon as any Virginian attempts to pin him to his wager, and make him responsible for it. To do this, Mr. Prince will be at no loss; for his advertisement offers plenty of "holes to creep through," and for him so to escape from the consequences of his blustering challenge. "The truth is," that Mr. Prince has far too much sense to stick to any such bet as he *seems* here to offer. But if he dares to maintain his offer, in good faith, and will put it *in precise and definite terms*, so as to permit fair trial, comparison, and "competition," and so as to clear up fairly the point in question, (the superior growth and maturity of the wood, in open or naturally exposed culture, in Virginia and in New York,) then he can have the bet taken up much sooner than he wishes, and for a much larger amount than he here *pretends* to put at hazard.

The concluding assertion, that "*the truth is*, their growth is as great in Rhode Island and Connecticut as in Virginia," is so grossly and manifestly false, that it does not deserve any other than this mode of reply. I should as soon attempt seriously to disprove, what would be an equivalent assertion, that the climate of New England was as warm as that of Virginia, and the summers as long.

The numerous purchasers of the plants and seeds of the Messrs. Prince, have submitted, silently, long enough to their mode of dealing; and for them, in addition, to have also such gross imposition as this attempted—such insult offered to their understanding, is pressing too heavily, and perhaps dangerously, upon their forbearance.

The Messrs. Prince will not dare to repeat the offer of their bet in precise terms, and on fair conditions; or make themselves responsible for an issue so made up. ANTI-PUFF.

MONTHLY COMMERCIAL REPORT.

The grain and flour markets have been in a fluctuating state during the present month. Prices advanced in England, until the average of wheat reached 73 per quarter, when the duty being reduced to its minimum, all that was in bond, or that arrived at the moment, was entered for consumption, amounting to a million quarters, or 9,333,000 bushels of 60 pounds. The averages of the succeeding weeks were progressively lower, so that the duty gradually advanced, and this has prevented shipments of flour from the United States. The price of wheat in our markets has been $1 55 to $1 75. Of flour $8 to 8 50—supplies have not been large, except at New York, where receipts by way of the Erie Canal, &c., reach 4,000 to 11,000 bbls. daily. The seeding of wheat in Virginia is unusually late—excessive drought, succeeded by rains almost as excessive, having prevented the farmers from preparing their land.

The crops of wheat on the continent of Europe, are reported to be much below an average.

The price of tobacco has advanced in all European markets, and is fully supported on this side—ranging from $6 50 to $13 50 for lugs and leaf. The crop now preparing for market is variously estimated from 20,000 to 30,000, and that of Kentucky at 20,000 to 25,000 hhds. The quantity inspected in Virginia, for the year ending 1st inst., was 41,800, and the export to Europe 21,000 hhds. The receipts in New Orleans to same period, were 38,100, and the export 37,100, of which a large portion was shipped coastwise. The stocks in Europe are very moderate. The quantity manufactured in Virginia is 18,000 to 20,000 hhds. exclusive of 7000 hhds. leaf converted into stemmed.

The receipts of cotton are thus stated:

	1837.	1838.	
N. Orleans and Natches,	601,014	731,256	bales.
Mobile, - -	232,243	309,807	do.
Florida, - -	83,703	106,171	do.
Georgia, - -	262,971	304,210	do.
S. Carolina, -	196,377	294,334	do.
N. Carolina, -	18,004	21,439	do.
Virginia, - -	28,618	32,000	do.
At Northern ports inland,	-	2,280	do.
	1422,930	1801,497	

A considerable quantity of old cotton remained in the country in October 1837, so that the relative production of the two years may be stated at 1,560,000 and 1,660,000 bales.

The exports to Foreign ports were:

	1837.	1838.	
To Great Britain,	850,786	1,165,155	bales.
France, -	260,722	321,480	do.
South of Europe	30,480	25,895	do.
North do -	26,437	63,099	do.
	1,168,525	1,575,629	

The quantity consumed in the United States, (not including the factories south and west of Virginia,) was, in 1837, 222,540—in 1838, 246,063 bales. These estimates are all made from October to October.

The stocks in all our ports October 1837, were 75,820 and October 1838, 40,300 bales.

The crop of the present year is supposed to be smaller than that of the last, particularly in the Atlantic States. In North Carolina and Virginia, it is not only much less in quantity, but inferior in quality. The price in Petersburg is 11 to 12 cents, being ½ cent below that of old, the stock of which is nearly exhausted. The mills at this place are all in active operation, and the erection of new ones proposed.

The attention of some of our most enterprising farmers is now directed to the culture of silk, for which preparations are making, and no doubt is entertained of its success. Speculations in the *morus multicaulis* are carried to a surprising extent in every part of the country, and fortunes have been made from the reproduction of a few twigs.

The extension of the great line of railroads is now about to be undertaken, from Raleigh to Columbia, S. C., which will nearly complete the chain from Maine to Alabama—what, with steam ships and locomotives, space will be annihilated.

Oct. 29th, 1838. X.

Our correspondent, T. S. Pleasants, having seen the sheet (after the printing was finished,) containing the extracts of his private letters, deemed it necessary, to prevent the appearance of his having assumed too much, that it should be stated, that T. M. Randolph, esq., first suggested the scheme, and obtained from the government the lease of the Bellona Arsenal, for silk-culture; and that Pleasants became, by subsequent arrangement, one of the joint tenants and occupants of the property.

From Lawrence on the Horse.

DESCRIPTION OF A WELL FORMED HORSE.

The head of a horse should be void of flesh, and for length and size appear to hold fair proportion with the size of his body; his eye full, and somewhat prominent; eye-lids thin and dry; ears thin, narrow, erect, of middling length, and not distant from each other; forehead flat, not too large or square and running nearly in a straight line to the muzzle, which should be small and fine; nostrils capacious; lips thin; mouth of sufficient depth, and the tongue not too large; the jaw-bones wide at top, where they join the neck; the head not abruptly affixed to the extremity of the neck, but with a moderate curve and tapering of the latter.

The neck must be of moderate, not too great length, nor too thick and gross on the upper part, nor too large and deep, but rising from the withers or forehand, and afterwards declining and tapering at the extremity, it will form somewhat of an arch; underneath, the neck should be straight from the chest, and by no means convex or bellying out.

The shoulders capacious, and of large extent, so as to appear the most conspicuous part of the body, but without being loaded with flesh; they should reach fairly to the top of the withers, which must be well raised; the chest should be sufficiently full, not narrow or pinched.

The body deep and substantial; back, a plane of good width, but handsomely rounded; backbone, straight, or with a trifling inclination, and not too short; loins wide, and the muscles of the reins, or fillets, full and swelling on each side of the backbone; the space sufficient between the ribs and hip bones, the bones themselves round, and the buttocks deep and oval; the rump level with, or not too much elevated above the height of the withers; the croup must have reasonable space, and not sink too suddenly, in which case, the tail would be set on too low, which ought to be nearly on a level with the back.

The hinder quarters should spread to a wider extent than the fore-parts, and the hind-feet stand farther asunder than those before; the thighs should be straight, large, muscular, and of considerable length; the hock wide and clean; the shank not too long but flat, and of sufficient substance, its sinew large and distinct, the fetlocks long; the hocks should form an angle of such extent as to place the feet immediately under the flanks. The fore-arms, like the thighs, should be large, muscular, and of good length, the elbows not turning outwards; the knees large and lean; the shank or cannon-bone, flat, strong, and not too long; the tendon large; the fore-arm and shank must form nearly a straight line; fetlock-joints large and clean; pastern inclining to a certain degree, not too long, but large in proportion to their length; the coronary rings not thick or swelled, but clean, dry, and hairy; the feet neither too high nor too flat, and of size apparently a sufficient base for the weight they have to sustain; hoofs, of color dark and shining, without seams or wrinkles, tough and strong, not hard like oak; foot internally concave, soal hard, but not shrunk, heels wide, and of middling height; frog not too large or fleshy, but tough and sound; the feet of equal size, should stand exactly parallel, so that the front or toe incline neither inward nor outward; the fore-feet should stand perpendicular to the chest, not too much under it, and they should be less wide apart that the fore-arms; the legs should not be loaded with hair.

EDMUND RUFFIN, EDITOR AND PROPRIETOR.

TREATISE ON THE CULTURE OF SILK.

BY GIDEON B. SMITH.

[Supplemental to No. 2, published in the November number.]

After the cocoons have been properly cured, as described, either by baking or the application of heat in any other way, they should be spread out in a dry airy room, that the moisture of the chrysalis may evaporate, and should be thus kept till wanted for reeling or transportation. I have known cocoons to be ruined by the moisture of the chrysalis, when merely thrown into barrels and boxes. When intended for transportation, or to be sent to any distance, after they have been thoroughly dried, they may be put into barrels, boxes, or baskets, but must not be packed so as to *indent* the cocoons. The best way is, to fill the vessel, and gently settle them down, by shaking and slight pressure. If the cocoons are indented, they are very difficult to reel, and if flattened, they cannot be reeled at all; and, of course, are worthless, except for carding. In very damp weather, the room in which the cocoons are kept, ought to have a fire made in it to dry the air, and the cocoons should be stirred up, once a day, during the continuance of such weather; as they are very apt to absorb moisture from the atmosphere.

No. 3.

Reeling, twisting, bleaching, &c.

We have now arrived at the most difficult part of the whole business of silk-making, that of reeling the cocoons--without which all the previous operations will have been worthless. It is at this point that thousands of persons who have begun the culture of silk, under high hopes and expectations, have been arrested in their progress by what they called insurmountable difficulties, and abandoned the business in despair—there being, heretofore, no market for the sale of cocoons. In vain, have they been exhorted to persevere in the trial with patience and industry for a few days—in vain have they been told, that the devotion of one week's time and half a dozen pounds of cocoons, would be sufficient to teach them the art. The process seems so tedious, the result so trifling, that, after a few hours' trial, they give it up, and thus ends their career in the culture of silk. More than one thousand such instances have come under my immediate notice—I might, I am sure, say several thousands, including all with whom I have had intercourse personally, or by letter. Among them all, not more than one in twenty, have been induced to persevere, until they learned to reel at all, and not probably one in fifty until they learned to reel well. But for the encouragement of those who wish to learn to reel, I can and do assure them, that, when any intelligent persons have persevered for one week, they have invariably become expert reelers in that time, and many of them even in less time. Any person, therefore, that will devote one week, and five or six pounds of cocoons, steadily and perseveringly to the object, will be certain of accomplishing it. It requires almost Job-like patience, but patience was never better paid for. Let this be an invariable rule with all who would learn to reel: Take five or six pounds of cocoons, and set apart one week of time, with a determination to *waste* all the cocoons, if necessary, and to allow of no interruption, during the time, and then go a-head. If in two or three hours you find yourself making a good thread, all the better; but don't be discouraged if you presently find that thread becoming worthless from some cause or other, but take it off the reel, and begin anew. Who ever heard of a young woman learning to spin cotton, wool, or flax, even in one week's trial? Why, then, expect to perform a much nicer operation by *intuition?* Persevere, then, and you will learn. Perseverance, in a learner of reeling, is the great thing needful; and it is sure of its reward. Let me, for further encouragement, inform young beginners, that I have taught many persons to reel by writing one letter to them, describing the process. Many persons now maintain themselves by making sewing-silk, who never had any other instructions than these letters.

The REEL, most proper for the purpose, has heretofore been the one established by the Italian government, called the Piedmontese reel. Its construction is peculiar; and it secures several points deemed important in raw silk. By a peculiar vibration of a particular part, it lays the threads cross-ways in such manner as to prevent adhesion by means of the still wet gum. It reels two threads at a time, and they are so wound around each other in passing up to the bars of the reel, that they compress each other into a perfectly cylindrical wiry thread, without twisting—which is important, as the raw silk can then be used as flax, or twisted more or less to suit the various purposes for which it may be wanted. Our countrymen, however, seem to have abandoned, or rather rejected (for they have never used them much) these reels, and are using various kinds of new construction. Almost every person that has done any thing at all in making silk, has invented "a new reel"—a "new silk-reeler and twister;" a "machine to reel and twist silk at the same time," &c., &c. I am, however, very much inclined to the opinion, that for all commercial purposes, the silk must be reeled in a manner similar to that produced by the Piedmontese reel, and that, or some reel producing the same result, must ultimately be adopted by us. All staple articles of commerce must have some fixed character as a standard, all deviations from which deteriorate its quality. Silk reeled by the newly constructed machines will do well enough, and as well as any, for sewing silk, and for other manufactures at home, and in our own looms; but in the markets of the world at large, it must be of a character and quality to meet the expectations, and to conform to the customs of the manufacturers there. Why does the raw silk of China sell in Europe so much lower than that of Piedmont?

simply because it is not reeled like the latter. I make these remarks, here, merely for the purpose of recording my opinion on this point, fully believing that the time will come, when all other reels and machines than that of Piedmont, or those producing the same results, will be abandoned in this country, except for domestic use, for which the newly invented machines are admirably adapted. The best I have examined is BROOKS'. They cost about $40, and can be obtained of the inventor, Adam Brooks, South Scituate, Massachusetts. Reels of the Piedmontese construction, can be obtained in Philadelphia, but I am not in possession of the address of the person who makes them at this time. They cost $15 to $20.

PREPARATIONS FOR REELING.—A small portable furnace, with some burning charcoal, is very useful for keeping the water hot, and should always be used. On this, place a copper or tin vessel, broad and flat, say six inches deep, 18 inches long, and 12 inches wide. Fill the vessel with hot water, not quite boiling, and put into the water two or three dozen cocoons, from which all the loose tow has been taken. With a small wisp of broom-straw, stir the cocoons about, occasionally raising the wisp to see if the end of a fibre has attached itself to it, and if such is the case, take the fibre in the left hand, and proceed again, as before, stirring the cocoons with the wisp, and securing the fibres in the left hand, until you have got fifteen or twenty; then attach them to the bar of the reel, and let an attendant turn the reel rapidly. Watch the cocoons carefully, so that you may observe if they *run* or unwind well. If you observe any of them drawn up out of the water, the water is not hot enough; if the fibres come off the cocoons in burs or clusters, the water is too hot. In the former case you must increase the heat of the water by pouring into the pan some boiling water; in the latter case you must cool it, by putting in cold water. The great difficulty, in reeling, consists in ascertaining the proper degree of heat of the water, required for different parcels of cocoons. Some cocoons require the water to be only of blood-heat; and others of all degrees from blood-heat to near the boiling point. But a little experience will teach the degree of heat required, so that the reeler will know in a moment whether the water is of a proper temperature.

When you have got as many fibres running on the reel as you require, you must still sit at the pan with the wisp, catching other fibres; for if the reel is turned with the proper rapidity, it will require you to be constantly attaching new fibres to supply the place of those that have broken, or exhausted cocoons. The fibres are readily attached to the thread as it is running, by merely throwing the ends of them on the running thread, which immediately adhere by means of the gum.

THE NUMBER OF FIBRES in the thread depends upon the purpose for which the silk is intended. For sewing-silk of ordinary quality, about fifty fibres may be reeled together; and then the threads will require to be doubled, so that from one hundred and fifty to two hundred fibres are contained in an ordinary thread of sewing-silk. For coarse broad goods, the same number may be reeled; but for the finer goods, gauzes, &c., five to ten fibres only, or for the finest, only two fibres are reeled together.

If the learner has followed the above instructions, he has probably been able to get quite a skein or hank of raw silk on his reel. I am sorry to disappoint him, but must tell him, it is good for nothing. I was desirous of enabling him to get the *knack* of catching the fibres; attaching them to the running thread; of learning the proper temperature of the water; and giving him a little experience in nearly *winding off* a parcel of cocoons, that he might become acquainted with the outlines of the art, and get the *use of his tools*. As said before, the silk reeled *merely* as above, will generally be worthless—it requires more care.

If the Piedmontese reel be used, two threads, of ten to twenty or thirty fibres each, are attached to the reel at the same time, and kept constantly of the same number of fibres. The proper number of fibres is obtained as before directed; brought together, drawn through the hand to clear them of motes and filth, and then drawn out to see that they run well; then pass them through the eye of the plate, pass the two threads three or four times round each other, separate them and pass them through the eyes on the vibrating bar, thence to the bar of the reel; as soon as they are attached to the latter, let the attendant turn the reel rapidly, and the reeler return to the pan to provide fibres for those cocoons that become detached or exhausted.

It will keep the reeler pretty busily employed in catching fibres, and dexterously throwing the ends upon the thread as it passes up, to keep the proper number of cocoons running in both threads. Keep a basket of cocoons by your side, and put in fresh ones to supply the place of those already in the basin, from time to time, as they are exhausted. Take care that there be not too many in the basin at the same time, nor too few; as in the former case, some of them will become too loose, and in the latter, the reel must stop till the fresh ones are soaked enough to run freely. Observe the following rules strictly: Whatever be the number of fibres you begin with, keep that number steadily in the thread, that it may be uniform and even; change the water as often as it becomes foul, and always use perfectly clear rain or river water, letting it stand for a time before use, that the sand, if any be in it, may settle before putting it into the pan. Well or spring water is generally too hard for the purpose. Avoid all carelessness and slovenliness—and remember that, CARE IS MONEY, in reeling silk. Let it be borne in mind, that the value of silk is increased or diminished by the manner in which it is reeled, very materially. One reeler will make his day's work in reeling worth five or six dollars, while another will only be worth two or three dollars, both reeling the same quantity of cocoons. Hence the value of care and attention. Attention to SMALL MATTERS, too, is here of the utmost importance. Indeed, the whole process is but a series of small, *very* small matters, no one of which can be neglected but at the expense of a material reduction in the quality of the silk. For example, if the water be too hot, the thread will be knotty, from the kinks or burs of the fibre that run up; if it be foul, from allowing the shells of the chrysalids to remain in it, the silk will be covered with motes; and if the number of fibres be not constantly kept the same, the thread will be uneven; all which deteriorate the quality of the silk, and therefore reduce materially the profit of the day's labor; but all which can be obviated without difficulty, by strict attention. I need not harp upon this subject longer, I am sure. Those who will take the above advice will profit by it; those who will not, will be forced to adopt it by experience.

After an ordinary sized skein is wound upon the bars of the reel, it is to be taken off, hung up, and another skein commenced in the same manner. The reel generally has two or more sets of arms, and when a skein is full, the arms or running part of the reel is taken off the frame and set aside to dry the silk, after which it is taken from the bars, placed upon a *swift*, and wound on to bobbins; when any number of the bobbins may be combined, called doubling, and twisted together on a common spinning wheel, to make sewing silk.

If it be intended for sale in the state of raw silk, the skeins are to be carefully twisted and doubled, and thus brought into a compact form, tied with a string, and thus packed up for market.

For SEWING SILK, a sufficient number of bobbins are to be combined to make one thread of sewing silk, twisted on a common wheel, reeled off into hanks, the latter twisted partially, and folded by taking two or three turns, as in preparing common yarn for dying, put into some perfectly clear rain or river water, in which a quarter of a pound of good country soap to the gallon of water has been dissolved, and *simmered* over the fire three or four hours, or until the silk is perfectly freed of its gum, and becomes white. It must then be taken out, rinsed in hot rain or river water, and then in cold water. In this operation great care must be observed to dip it gently, drawing it to and fro in the water, so as not to get the silk tangled, or in a snarl. It is then to be hung up to dry; after which it may be doubled and twisted into sewing silk. It should never be put up into large skeins, as it is apt to get tangled. One hundred threads is a good sized skein. If the whole work has been properly done, the silk will be beautifully white, with a rich gloss.

Before the last twisting for sewing silk, if to be colored, it may be dyed of the desired color, and then twisted.

The above directions will apply to all kinds of reels generally. The only difference consists in the following particulars. With Brooks' and other reels of American construction, the silk is run directly upon bobbins, two or more bobbins are combined, and the thread produced passes through fliers and is thus twisted; it is then wound upon a common reel into hanks, and folded for bleaching by boiling, as above described.

Brooks' machine is said to reel double and twist at the same time; but it does not do it strictly speaking. The thread first passes on to the bobbins partially twisted; when the bobbins are full, the thread from two or more of them is combined, and passed through the machine again, when it is twisted into sewing silk. There are four fliers to this machine, two are used for reeling and the other two for doubling and twisting the silk that has before passed through the other fliers. I think it were better to use all the fliers for reeling; and after reeling as much as is desired, then to use all the fliers for doubling and twisting. For domestic family purposes, this machine is admirably adapted. It makes excellent sewing silk and thread for knitting. Large establishments will of course not need instruction as to the machinery to be used, from me.

WASTE SILK, perforated and imperfect cocoons, may be easily converted to useful purposes. The cocoons are to be cut open with scissors, the shell of the chrysalis taken out, and the cocoon, together with all other waste silk, put into water, and the gum extracted as above. It is then to be rinsed, dried, picked fine, carded and spun like flax-tow, and makes most beautiful and durable stockings and gloves. The better method is, after the gum has been extracted, to take the mass of fibre, stretch it out, and cut the whole into pieces five or six inches long, like cutting a skein of yarn. The fibres are then not too long for the operation of carding.

Concluding Remarks.

I have now given all the instruction necessary to a complete domestic silk establishment; such as will enable every farmer's family to pursue the business in a domestic way, and to make it the most profitable *pin-money* affair to which the young ladies can possibly turn their attention. Indeed all they make from it will be so much clear gain; for none but otherwise idle hours need be appropriated to it, except in the reeling, and in most cases not even in that. A young lady in any farmer's family, can thus make five to ten pounds of sewing silk or knitting silk, or raw silk for sale; and not only not work hard, but do scarcely more than occupy hours that would otherwise hang heavily on her hands.

I feel called upon by the peculiar situation I occupy, to make a few remarks in relation to the profits and prospects of the silk-culture in the United States. I have said before, that we shall become a great silk producing country; that ere long we shall supply the factories of Europe with the most valuable part of their raw silk, as we do now with cotton. This I conceive nothing can prevent. That we shall also, in the course of no very long time, become the manufacturers and exporters of finished silk goods, is clearly inferrible from the first proposition. From this it will of course be inferred that I consider the production of silk, in all its branches, a profitable business; and I do so consider it. My experiments for twelve years past have clearly satisfied my mind upon this point. But I do not consider it as profitable as many of the ardent friends of the cause would make us believe. I do not consider it sufficiently profitable to authorize farmers, mechanics, lawyers, doctors, and merchants, universally to abandon their old and well understood pursuits, to enter into this, which they do not understand. It is undoubtedly a safe and a lucrative business, when well understood and well pursued; but that *any body* can give up his ordinary occupation, step into this, and make his fortune by it, like the drawing of a prize in a lottery, must not be expected. We often see calculations made of the amount of money that can be made from an acre of ground. All such are clearly fallacious. No dependence can be placed upon them, simply because the business has not been sufficiently practised in this country to afford any good grounds for them. And then, again, as *labor* with us is more costly than land, it is more proper to inquire how much *each hand* can make, especially as more than nine-tenths of the value of the silk is derived from the labor expended in its production. But no estimate can be made even of the profits of labor in consequence of our want of experience. But that we shall ever realize the great profits from this business that we are continually told we shall, seems improbable from the very nature of things. Why, if such great profits can be made from the culture of silk as $1000 to $2000, from an acre of ground, and that too, as we are told, with very little labor, and to the extent of as many acres as we please, why, I ask, are not France and Italy, nay all the south of Europe, where silk has been made for ages, universally engaged in the business? Why are they continually purchasing the raw silks of the east for their factories? Will any people import an article for consumption that they can produce at home at less cost? Labor is cheaper there than here, and consequently one would suppose they could make as much profit by the silk culture as we can. It is true we have several important advantages over every other country. We have a climate better adapted to it; our people are more enterprising and industrious; we can use the morus multicaulis, (which they cannot, on account of the difficulty of getting over ancient prejudices, and of substituting it for their already established trees of other kinds.) But we have also our disadvantages, the principal of which is the cost of labor. We cannot expect to do much more with our advantages than to make them offset the disadvantage of the cost of our labor. Suppose, however, we do realize double the profits that they do; even then we shall not make any thing like the profit we are told we shall. If the silk-growers of Europe made any thing more than a good living business of it, every body there would immediately go into it; for there, as well as here, and every where else, all very profitable professions, or trades, are sure to be immediately filled with occupants, and thus overdone. Another view. If the business was so very profitable, the prices of the article would speedily be reduced by competition, until it afforded a fair profit merely. It is so in all other branches of trade—why not in this? The French and Italians are surely as capable of estimating the value of things as we are. If silk can be made for four dollars a pound, and it costs six dollars to import it, we may be sure that it will be made, not purchased. These remarks are not made to discourage persons from going into the culture of silk; but rather to prevent disappointment in those who are led astray by over sanguine estimates. I find myself placed in a singular predicament. For many years past I have been urging this business upon public attention, and doing all I could to induce our people to go into it; now, on the contrary, I feel called upon to restrain the spirit I have heretofore spurred to action. In this I anticipate that I shall be accused of inconsistency. But, if I am properly understood, no such fault will be discovered. Now, as heretofore, I urge upon farmers every where to introduce the business into their domestic affairs. Let the people of the *poor-land districts* of the old states introduce it there. It will be as profitable, if not more so, than the cotton crops, and grain crops of other and more favored districts, and will thus serve to equalize the productions of all parts of our country. The old worn-out lands of Maryland, Virginia, North Carolina, &c., cannot by any possibility be put to a more profitable use. But neither in this nor in any other case where it is made an exclusive business, must it be expected that enormous profits are to be made. It must be remembered, that *great profits* cannot be made in any business for any great length of time, simply because every body will go into it, overdo it, and thus reduce its profits to a mere living rate. With these remarks I take leave of the subject.

GIDEON B. SMITH.

From the American Farmer.

ON BUILDING AND FILLING ICE-HOUSES.

Latitude 39°
October 15, 1823.

Sir—I would not give one solid ounce of experience for a whole ton of theory. I have an ice-house, the pit of which is 6½ feet, the earth thrown out raised a good mound 2½ feet more, making 9 feet to the bottom, which is a tolerably dry sand. It was for many years a pit with a pen inside, made of flat pieces of mauled oak—the earth came to the back of the logs. In the centre of the bottom there was what was called a dry well—that is, a round hole a foot deep, of which I have never perceived the advantage. The same kind of mauled pieces laid on the bottom, formed the floor—the pen was about 11 feet square in the clear, with a capacity of about one thousand cubic feet. A thatch of corn tops on poles, formed the roof and cover, with a door of entrance into the north end. This house used to hold about from 30 to 35 common sized ox-cart-loads; the ice pounded from the size of a walnut to a brick.—It generally kept ice till the middle of August, and then left us more disagreeably off, than if we had not enjoyed it at all. It was near the poultry yard, and the blame was laid on the poor hens, which, fond of a cool place to nest in midsummer, used to scratch holes in the bottom of the thatch, and let in the rain water. This was often one cause of the loss of the ice, but not the only one. The fact was too well established, the ice seldom reached September—and I became fully convinced that the principal reason of the early loss was, that the mass of ice was too small. The rats also plagued us very much in the chief use of a country ice-house, the preservation of fresh provision.

I determined to endeavour to remedy all the faults. With this view, the old work, now much out of repair, was broken up—the pit enlarged to 16 feet by 24, in which a 9 inch brick wall was run up to 6 inches above the ground, and the floor was paved two bricks thick—the pit was then 14½ feet by 22½ feet in the clear; and 8½ feet deep to the surface of the earth. On the pavement I laid four sills, on which I raised a frame, 11 feet by 19 feet in the clear, with sleepers 6 inches deep, resting on the pavement. The top of the frame even with the brick work.—A tight floor of good plank was laid, and the frame planked up tight on the inside.

This plank pen, or pit, is 11 feet by 19 in the clear. There is of course, a space of about 20 inches all round, between the plank and the brick work.

The design in making the pit oblong, was to take off 7 feet of one end, and appropriate it to milk in the summer season—but having a cool dairy which keeps milk pretty well, this was never done; and the whole pit containing upwards of 1500 cubic feet, has been used for ice.

Above ground, upon the brick work, there is a frame house 24 feet, by 16 feet and 5 or 6 feet pitch. This house is but half boxed, and the air is freely admitted between the main and false plates. There is an upper floor laid on the joists, except a space about 2 feet by 6 in the centre. Directly over this space there is an aperture 6 feet by 6 or 8 inches, in the ridge of the roof, over which aperture there is a bonnet to keep the rain out. The sides and the ends from the aperture in the floor, to that in the roof, are planked, so as to prevent any opening between the loft and this centre ventilator. By these contrivances, the loft is kept stowed full of straw to produce more than the coolness of a thatched roof, and yet the air has an uninterrupted passage in at the eaves, and out at the ridge. There are a few narrow strips of plank nailed a foot apart on the innersides of the studs--and the space between the weather-boarding and the strips is also filled with straw.

On the south side of this house there are trees, which break the rays of the mid-day sun from the roof. The body of the house is kept white and sometimes the roof.

When first used, the space between the bricks and planks was kept clear; with the idea that the air would prevent the damp from the earth and bricks going to the planks—but experience has fully proved in this latitude, that from the last of February the air should be kept as far from your mass of ice as possible. For several years this space has been kept well filled with dry straw. We have ice in this house, at this time, and since it has been packed in the manner now pursued, it has not been unusual to have ice, till ice has again returned.

The mode of putting the ice up, is considered very material, and is as follows. The space between the bricks and planks is examined, and seen to be well packed with dry straw—the plank pit is made perfectly clean. The ice is brought in as large cakes as can be conveniently handled, and in as regular squares or oblongs, as they can be conveniently cut and broken by the eye and axe. These cakes are laid upon the naked plank floor of the pit, leaving as small joints and crevices between as possible. A trough or old canoe is placed near the door of the house—into this the small pieces and broken bits are put and pulverised quite fine, and the crevices between the layer of cakes is well filled with it; the surface of the cakes being kept clean.—A second layer of cakes is than laid down, and the crevices filled as before—and this simple method is continued till the pit is full. A very little care will keep the surface of each layer level, and the whole will go in as solid as a piece of stone-mason's work.

No straw is put on the floor under the ice; because experience has proved it is not necessary, and because if it should become wet, and need to be removed ever so much, it cannot be got at. Nor is there any put between the side planks of the pit and the ice at the time of packing, because it is not then necessary, nor can it be well done at that time.—With all possible care the straw will mix with the ice and be put in irregularly.—Whereas if the pit be filled solidly and entirely with ice, as soon as the ice begins to shrink from and leave the sides of the pit, this regular vacancy can be well crammed with dry straw, and if this straw get damp, it can be easily taken out and changed. But if the straw had been put in the ice, it would take up more space, and from its irregular stuffing, would be found much more difficult to remove, should it become damp or mouldy.

About the last of February, the mass of ice is covered over with dry straw, not less than three feet thick, and if straw is plenty, the house from the ice to the joist is filled with it. It is considered very necessary to keep it wrapped under a thick coat of straw, sedge or dry leaves. Should the straw next the ice become damp, be careful not to expose the ice to the air, but begin at one end, and let the damp straw be pulled out—and the next straw above, which is not only dry, but cool, be suffered to settle down on the ice. If you have more dry straw, let as much as was taken out wet be brought and put on the top of the straw in the house—or let the damp straw be dried and sunned, and then returned on the top of the straw in the house. Never think of changing the whole mass of straw on the ice at one time, by bringing fresh straw from the barn yard, for this dry straw from the barn-yard will always be of a much warmer temperature than your ice, and will be sure to melt it very much.

The advantages of packing ice in the above mode, over the common method of pounding into small lumps, are many, and striking. In the first place, if the ice be three inches thick, or more, it can be stowed quicker with the same hands. Again, you can pack much more ice in the same space—my house that used to be filled with forty-eight ox-cart-loads of ice when pounded, has often taken in seventy of the same sized loads, when packed in the whole cake—and this will not appear at all surprising upon a moment's reflection. By pounding, you do not pack it; but infinitely multiply the pores and crevices—any miller knows, that a bushel of corn when pulverized, or ground into fine meal, will measure out not far short of a bushel and a half. Any wood-cutter knows, that a cord of round logs, say a foot diameter, with the insterstices filled with small round wood, if the logs be split or mauled into marketable wood, will measure near a cord and a half fair measure. But, sir, I will give you an example exactly in point, and which, at least, any countryman can try. Recollect, *pounding* ice is very far from *packing* it. It is not compressible like flour in a barrel under the action of the packer. Take an ear of corn, roll it in half a sheet of paper—let the paper come just even with the but, or large end of the ear, and an inch or two beyond the small end—twist the paper at the small end, and tie it with a string all round so that when the ear is drawn out, the paper will form the exact case of it. Draw the ear, shell it, and return the grains into the paper case. If the ear is of the gourd seed, or of a kind having long grains and a small cob, the grains which will lay packed exactly like the slippery hard-pounded ice, will be found nearly to fill the paper case, notwithstanding the whole cob has been withdrawn.

If, sir, you are not now convinced that seventy loads of ice can be packed where forty-eight only will stow when pounded—nothing need be said to attempt to convince you that a mass containing the greater number of loads, will keep longer than one containing only the less number. But this is not all—when the ice comes into use, that which was packed is easily raised in large, native, solid, brilliant lumps, which will last more than twice as long, after being brought to the cooler, &c. as that which has been pounded.

I thought I would have given you the size and plan of a good cheap ice-house, I have already trespassed too far with the long story of my experience. Your obedient servant,

CRŒSINUS.

From the Penny Magazine.

THE FORESTS OF AMERICA.

Those who have never explored the primeval forests of America, can form but a very imperfect conception of the depth of the gloom and solemnity which every-where prevades them. Save on some of the south-western ridges, such as intersect the great valley of the Ohio for instance, where, beneath the outspreading branches of the oak, the chestnut, the walnut, and the sycamore, you find spots of luxuriant herbage, and myriads of bright and beautiful flowers, all the rest of the interminable woods that I ever, in my devious rambles, have explored, are wholly destitute of herbage, yielding neither grass nor flowers. Wherever you tread, the surface of the ground is thickly strewn with decayed and decaying leaves; and dead branches, of various shapes and sizes, are daily toppling down from the lofty stems to which they have belonged. And though the winds may rage, and the storm may beat, in the tops of the tall forest-trees, yet there reigns an everlasting stillness near the surface of the earth; not a breath of air is there to stir the light and withered leaves: where they fall, there they are suffered to moulder and decay. The boundless covering of crisp and brown leaves becomes partially enlivened by the green of the young seedlings, which spring up by thousands during the summer season; but as the all-vivifying influence of the glorious orb of "light and life" cannot reach their lowly condition, for the most part they pine and die, their places being supplied with another crop of these "annuals" each succeeding summer.

It would be tedious to enumerate all the varieties of timber-trees found in the vast wildernesses of America; yet there is, in almost every section of the country, some predominant species, from which the woods acquire their appropriate name and character. The chief of these may be comprised in the four following, namely,—oak-woods, beech-woods, pine-woods, and cedar-swamps, or barrens. All these forests are gloomy, but they have their comparative degrees of depth of shade: the oak-woods being the least dark, because of the trees standing further apart; the beech-woods in the next degree; and then comes the sullen pine; and, lastly, the sombre cedar. When the sun is in its meridional summer splendor, a quiet, chaste and mellow light is admitted through the veil of pale green and semi-transparent foliage of the oak and beech woods. At that season, too, a few, but only a very few, summer-birds frequent forests of this character; and whose song, if song they have, is wild, monotonous, and melancholy. Occasionally, the ear is startled by the loud tapping of some industrious but unmusical woodpecker; and even in the depth of winter, its rapid hammering may be heard from afar,—for some of the more hardy varieties of the woodpecker tribe do not migrate at the approach of the most inclement seasons. Besides the few birds that usually frequent these forests, they are inhabited also by playful squirrels, of three or four varieties; their haunts, however, being generally confined to those tracts of country where mast and nuts are in the greatest abundance; for in all the northern regions of America they have to store up provisions during the summer and autumn, on which they have to depend for a subsistence through a long and rigorous winter. I have already enumerated all of animated nature that tends to lessen the gloom and loneliness of the oak and beech woods; for the larger animals which are found there are but rarely seen: and from their wild and savage habits and dispositions, the heart of man can derive no pleasurable sympathies or feelings.

I have described these forests as they appear to him who explores them during the sunny season of summer; but when the early frosts have seared the foliage of the oak and the beech,—and the autumnal tempests have scattered the leaves of the walnut, the ash, and the maple,—the light of day is more freely admitted through the lofty branches of the forest trees. But the birds of summer are gone; and should the season be pretty far advanced, the nimble-footed squirrels will have retreated to their holes and cavities in their favorite trees, no more to be seen sporting and frolicking until the warm and congenial suns of the ensuing spring shall awake them to renewed life and activity. Even the larger wild animals will have become more scarce by the time that winter has fairly set in, for some of them will have gone into their retreat, and have become torpid; and those that remain, being now able to discover man's approach at a greater distance, in consequence of the foliage no longer impeding the view, seldom suffer themselves to be closely approached. The winter snows lie smooth and unruffled in the wilderness, save where is seen the trail of some stalking deer, or the track of some prowling fox or wolf. In the mountainous districts, you occasionally come upon the footprints of the American panther; and in some of the western regions, the traveller will have an opportunity of remarking upon the trails of small herds of elk that have crossed his forest-path.

I come next to speak of the pine woods, and although they are not so common as the "green woods," as those already described are familiarly called,—yet there are millions of acres of forest, where pine, of two or three sorts, is the only, or at all events the generally prevailing timber. When the summer sun is in its full power and splendor, the light, if light it may be called, in the pine woods resembles faint and dubious twilight. This greater degree of obscurity is caused, partly by the darker and more impervious nature of the foliage, and partly in consequence of the pine-trees growing closer to each other than other forest trees generally do. Neither is there any season in the year in which the trees are bare;

much of the winter snow lodges on their branches, and that which finds a passage to the earth seems to have been deprived of all its native purity in the gloom of the recesses where it reposes. As regards the loneliness and melancholy of these regions, summer and winter are nearly alike; for during the season that rejoices all other parts of the creation, no summer bird resorts to the pine-clad regions to build its solitary nest, or chant its simple song of happiness and love. Scarcely a busy woodpecker is to be heard, (seeing one is out of the question); and as for squirrels, they find no business there; except in their migratory excursions instinct should happen to guide them through some section of a pine forest. The bird most commonly found there, is the New England partridge, or the Virginia pheasant; but even these are scarcer than they are in the more cheerful "green woods" of various parts of the country. It may be observed, that the pine forests are considerably taller than any of the rest; probably 160 feet would be below their average height; and although so very tall, the trees are seldom more than two feet in diameter, in consequence of their growing in such close vicinity. In the green, or summer woods, you frequently fall in with a few straggling pine trees, growing up amongst the light green foliage to the height of 60 or 70 feet above all the surrounding forest trees; standing like sentinels set to watch over all the silent wilderness. And when one has an opportunity of looking down upon the surrounding woods from some lofty and abrupt eminence, the whole country appears covered with brushwood or shrubbery, with here and there a pine tree of moderate size, shooting up from the midst of it. The white pine forests are the most general, as well as extensive, in the northern regions of America.

The cedar-woods are commonly confined to swamps; but they occasionally intervene on mountain ridges, where the soil is miserably poor: and, the trees attaining but a small size, such situations are called cedar-barrens. There are also oak, as well as pine barrens, in various parts of the country. The pine woods, as already stated, are dark and gloomy; but the cedar-swamps are still more dismal. Although they are seldom of great extent, to be under the necessity of traversing a few miles of these swamps is no ordinary undertaking; for, in many situations, the cedars grow so close to each other, that there is barely space for a man's body to squeeze through between them. And, taking into the account the nature of their dark-green foliage, some idea may be formed of the gloom and melancholy which for ever pervade the cedar swamps. Some of them are of so boggy a nature, that it is with extreme difficulty they are explored by man; and as the heavens are entirely shut out, the compass is absolutely necessary to direct the wanderer in the right way; and even this can hardly be trusted to as a sure guide, for there is not sufficient light upon all occasions to enable him to ascertain the quarter to which the needle points. One of the most extensive cedar-swamps known at present, is the Dismal Swamp, in Virginia; the length of which is upwards of thirty miles. In the interior of Canada, these swamps abound more than they do in any other section of the country with which I am acquainted; and notwithstanding the contiguous lands may be of the very best quality of soil, at the present day these swamps are utterly worthless. It is mostly the white cedar that grows in them, but the trees do not attain a great elevation, neither are they bulky, since very few of them exceed twelve or fifteen inches in diameter. Were other sorts of timber more scarce, white cedar would be in greater demand: at present, where it can be got to market at a moderate expense, it is used for laths, staves, and shingles. There is, if possible, a smaller portion of animal existence in these dreary regions, than in the desolate pine woods; for if we except the millions of mosquitoes that these swamps give birth to, scarcely is there aught that "lives and breathes" within the dark precincts of the cedar-woods.

There are some remarkable natural phenomena in the forests of America, two or three of which I will briefly notice; but as I have never heard what I consider satisfactory arguments advanced to account for their existence, I shall forbear hazarding any opinions of my own. In journeying through the interior of the country, where the forest has been little, or not at all, encroached upon by the axe of the woodman, you will often, after travelling for two or three days through regular pine woods, suddenly and unexpectedly find yourself in woods of a perfectly distinct and dissimilar character. This, in itself, is nothing extraordinary; but if you will take the trouble to examine a little into the matter, you will then find that there is no visible natural reason for this change; since, for all that you can discover, the soil, and all that is therewith connected, is precisely of the same character and quality on both sides the line which marks the change of timber. At other times, a small and insignificant stream will form the line of demarcation, but if you examine you will find that there is not any change or new arrangement in the mineral kingdom between one side of the stream and the other. These changes, when they do occur, are seldom of small extent, for you often find them running directly through regions of country for scores or hundreds of miles, every where showing the division line with a remarkable distinctness. And in those changes it is not only the leading character of timber which gives place to some other equally distinctive and prevailing: but the few inferior trees and shrubs are superseded by another set of secondary trees and shrubs, of a perfectly distinct order and character. Often from some lofty acclivity, have I stood gazing upon these dividing lines of the vast and wonderful timber-crops of the American primeval forests! when I could trace the divisions as accurately and distinctly as I could in my own grain-field, where a single furrow was the line of division between a crop of full-eared wheat on the one hand, and of the more plebeian oats on the other. In this case, I knew the cause; for I had said there shall be wheat here, and oats there, and it was so; because the proper and necessary seed was committed to the ground, and the respective crops sprang up accordingly.

In the new settlements, my agricultural pursuits have sometimes led me to witness changes which seemed altogether, to me, inexplicable. I will mention one of the instances to which I allude; and having related what I myself witnessed, and made a few observations respecting the situation where it took place, I will then leave the matter to be accounted for and explained by the learned in Nature's secrets—if they can. During the winter season the whole of the timber was cut down upon a piece of ground containing about twenty acres. This was in what was generally called the beech woods, from the major part of the timber being beech; but where there were also small quantities of maple, birch, ash, &c. During the following summer, fire was applied to this "chopped fallow," as the prostrate timber is called; and in the course of an hour all the dead leaves, the decayed timber, and the smaller branches of that which had been standing the previous year, were entirely consumed. Circumstances occurred which prevented the remaining trunks of the trees from being rolled together, in the usual way, and burned; so that in the condition described, this twenty-acre field was permitted to remain for several years. After the lapse of a year or two, the whole field became a plantation of young wild cherry-trees, although I am not aware that a single cherry tree was growing on the spot, or near it, at the time the timber was cut down. Some few of this species of cherry tree were to be met with in various parts of the surrounding woods; but it was altogether an exceedingly scarce sort of timber. During the first and second year of the growth of this young cherry plantation, I took considerable pains in searching for the cherry stones, (if such there were, or ever had been,) by pulling the seedlings up by the roots, and then examining the soil as minutely and carefully as possible. But for all my labor and research, I was not rewarded by the discovery of a single seed or stone! Had the young trees been left unmolested, here was a piece of ground, containing twenty acres, that would, in the course of forty or fifty years, (for this species of cherry is of rapid growth) have become a perfect forest of cherry-trees to that extent. Now, permit me to ask, is it probable that birds—for I have previously stated that very few inhabit the wilderness—should have brought hither all the cherry stones from which so many thousand seedlings, (I have no other name by which to designate them) sprung up in this identical spot? Or is it possible that all those young trees should have sprung up without there being any seed (cherry stones) in the ground at all? And supposing they were there, from whence, or when did they come?

On other occasions I have known oaks and hickories, and maples cut down, and instead of their places becoming supplied by a new generation of their own particular species, after the ground has been left uncultivated for a few years, a general and full crop of young pine trees has sprung up. Now here again, who or what could have brought the cones of some distant pine tree to this particular spot? And if they had been brought, was it by mere accident that they were strewn so regularly over the whole surface?

Far into the interior of the continent of America, in the midst of immense tracts of forest, you sometimes fall in with small openings,—patches of ground from which the Indians, or the early fur-traders, have taken away the timber, or perhaps consumed it on the spot. In some instances, these places will be overgrown with immense briers and brambles; but occasionally grass will have sprung up, and there you may find as luxuriant plants of the common white clover as are to be met with in any part of our own island, or even in the rich pastures of Holland. Here again is a dilemma. Either birds or beasts (and none but wild ones have ever been there!) must have brought the seed, or else it must have lain dormant in the soil, for I know not how many centuries, or the soil must have produced it spontaneously. I have stated these things precisely as they are; and all that I shall advance upon the subject, is, that I know them to be facts.

When trees tumble down in the forests through absolute age and decay, their places are generally supplied by saplings, that have long been struggling in the shade near them, either of their own or some other species. But when a chestnut tree falls its place is commonly filled by one of its own kind; for a number of sprouts shoot up from the root of the parent while it is still standing, one of which taking the lead of the rest, grows up in due time into a forest tree; while the rest of them droop and die for want of proper aliment. I have been able to trace distinctly three or four generations of the chestnut; for, owing to its decaying so slowly, the old fallen trees do not wholly disappear until their children and grand-children have grown up, flourished, languished in old age, and at last fallen beside them.

INDIA RUBBER, OR CAOUTCHOUC,

Is slightly analogous to silk. It is a remarkable fact, that all the plants the silk-worm feeds on contain a larger or smaller quantity of caoutchouc such as the lettuce, dandelion, mulberry tree, &c. In the Brazils, and more particularly in those parts where the India rubber tree (Ficus elastica) abounds, large moths, of from 2 inches to 3 inches in length, producing excellent silk, in large quantities, are very common. From the variety of useful purposes, to which India rubber is applicable, (from a lady's watch-guard or stay-lace, to a ship's cable,) a great demand has been created for this article, which has induced the mercantile world to bend its attention to it, as a valuable remittance. It is a singular fact, that, wherever the teak tree flourishes, there the India rubber plant may be found in abundance, namely, 20° north and south of the equator.—*Eng. Newspaper.*

From Loudon's Gardeners' Magazine.

ANTISEPTIC PROPERTY OF HONEY.

The best mode of conveying grafts of trees, cuttings of vines, &c., to a distance, is to place them in a tin case or cylinder filled with honey. The honey hermetically excludes the air; and cuttings so preserved will vegetate many months after they have been packed.—[Melons, and various fruits, are preserved in this way in Italy.—*Cond.*]

From Loudon's Gardeners' Magazine.

NOTICE OF MR. JOYCE'S APPARATUS FOR HEATING BY STEAM.

In the first week of June last, we called on Mr. Joyce, at his market-garden, in Camberwell, New Road, in order to see a mode of heating by steam which he has invented, and for which, he informs us, he has taken out a patent. According to this mode, a charcoal fire is made in the centre of the boiler of water, and the vapour from the charcoal is conveyed away in the same tube which carries the steam from the water round the house. The steam condenses in the tube, and the condensed water is all returned to the boiler; while the vapour of the charcoal is allowed to escape at the extreme end of the tube. The boiler, which is portable, and made of copper, occupies a very small space; and being placed within the house, and isolated, none of the heat generated by the fuel can, by any possibility, be lost; for even the heat that escapes at the farther extremity of the tube, along with the vapor, is still given off to the atmosphere of the house; and, however deleterious it might be for human beings, if allowed to accumulate, it certainly appears to produce no bad effects on plants, for a more luxuriant crop of strawberries than that in Mr. Joyce's forcing-house, we have never seen. * * * * * *

THE UNFITNESS OF THE NORTHERN STATES FOR THE MORUS MULTICAULIS.

The following extract from an editorial article, in the last Cultivator, strongly confirms the views which we have presented in several former articles in the Farmers' Register, as to the superior advantage of the climate of the southern states, for raising this valuable plant. There can be no higher authority than that of the editor of the Cultivator on this subject, as to the latitude of his residence, (Albany, N. Y.,) and of course, for all the more northern regions of the United States.

"In regard to the culture of this mulberry in our latitude, we have only to repeat the opinion we have often expressed, that the *tree* will not stand our winters, except, perhaps, upon a poor dry soil, when the growth ceases, and the wood hardens, before the occurrence of severe frosts. Indeed this is now virtually conceded by the growers; for we believe it is the general practice to secure seedlings in the cellar, or to bury them in the ground, and to cut down the trees, cover the stumps, and secure the tops and branches for propagation. Cutting down at autumn is recommended as the best mode of increasing the foliage, and as facilitating the gathering of the leaves; as many sprouts spring from the stump in the spring, and the leaves of which may be gathered without climbing."

In addition, we will here refer to a late and full statement in the Genesee Farmer, which was made to show the enormous increase *of about one hundred per cent.*, by the purchase of the cuttings, &c., and a year's culture of multicaulis, and the sales, or estimated value, at the late high prices in western New York. Now, though one hundred per cent. per annum is indeed a great profit, in a regular business, with prices of seed and crop nearly the same, yet in the late and present state of the multicaulis sales and speculation, a profit of one hundred per cent. is not worth mentioning, in comparison with the usual returns in Virginia and North Carolina; and any crop here which brought no more than one hundred per cent. of profit, or increase, this year, would not be worth making in ordinary years. An increase of forty-fold (in kind) is no rare product here; and if profits are counted in money prices, (as was done in the statement of the Genesee Farmer,) sundry cases might be adduced of actual profits being one hundred fold, or an increase of ten thousand per cent. in one year's cultivation. Yet this would be no more proof of ordinary annual profits here, than the statement of one hundred per cent. profit, made *this year* in western New York, is proof that the morus multicaulis can be profitably raised in that region, every year. We have no doubt but that all nurserymen and salesmen of the multicaulis plants, near navigable waters north of Sandy Hook, can more cheaply buy or raise their stock in lower Virginia, than they can furnish themselves at home. The expense of rent, agency, and transportation, would not by any means equal the disadvantages of the uncertain vegetation, dwarfish growth, and immature wood, of these plants raised at home.

SOME OF THE BLESSINGS OF EMIGRATING TO THE NORTH-WESTERN STATES.

Many of the people of Virginia have been long accustomed to consider and discuss, as well as to try, the advantages and disadvantages of emigrating to the new south-western states; but few, comparatively, have paid attention to those of the north-western states and territories. The known circumstances and supposed advantages of the latter were not such as greatly to tempt southrons. But still, the great natural advantages of this extensive and fertile region were universally admitted; and among these advantages, few of us would not have admitted, without question, the almost certain and exuberant productiveness of the rich lands, and the general healthiness of the residents, in so high a northern latitude. And these supposed and unquestioned advantages *have* operated to tempt a portion of southern emigrants to encounter the known disadvantages of that region, one of the greatest of which is the cold of winter, so long and so intense as to benumb the faculties, bodily and mental, for one-third of the year. But it seems that we have been too ready to admit the advantages of the north-west, in regard to health, and the abundant and sure production of the necessaries of life. In proof of grounds for this doubt, we annex several articles which have recently appeared in the several publications from which they are copied.

The first is from the Bangor Whig, and from the pen of the editor, who was then travelling in the north-western states.

"I cannot say I am so well pleased with what I have seen in the western country as I anticipated, but I am but ill qualified to judge as yet. One thing is certain, this part of the country, if it ever arrives at the greatness predicted, must do so through the deprivations and sufferings of the present generation. The present settlers are working hard for posterity—will posterity reward them? The common comforts and conveniences of life are given up,—people merely stay, dragging out an existence; toiling and sweating for the improvement of a country which it will take years to bring to a state of civilization, if one may so term it. The cities of the west are comfortable compared to the interior settlements, but even those are at present miserable places for men to live in, but yet they are inhabited. Chicago, for instance, on Lake Michigan, is below the level of the water in some places, and no where above it. No cellars can be dug because of water. Here lurk bilious and intermittent fevers and agues.

"The past summer, throughout the whole country, as you are aware, has been remarkable for its intense heat, and great drought—through the west this has been the case in a most extraordinary degree. The consequences are now being experienced, and they are indeed awful. A wide spread pestilence extending from the Ohio to the far west, is sweeping many to their graves, and causing an immensity of suffering. Places have been deserted, and the cattle turned in the unreaped fields. Whole towns have been sick—six or eight patients to a family—none have escaped, far and near this disease has stricken the weak and the strong. It is a bilious fever, not very fatal, it is true, but exceedingly distressing. I have scarcely seen a good looking countenance since I left Detroit. This fever is natural to this new country, and always prevails during the latter part of the summer in some places, and to some degree, but it has never before made the sick tremble and the well man turn pale. The fever will undoubtedly stop as soon as cold weather approaches."

"*Health of Iowa and Wisconsin.*—The Galena Advertiser and Gazette of the 10th ult., [Oct.] says:—'We have distressing accounts of sickness from almost every quarter of the inhabited parts of the territories of Wisconsin and Iowa, as well as many portions of Illinois. The motality, generally, we are happy to learn, in this affliction, bears but a small proportion to the number of attacks. The chief causes, according to all accounts, are bilious fevers, and fever and ague."

The next is from the Cultivator of November.

"*Sickness in the West.—The Land Sales.*—The citizens of northern Indiana have addressed a petition to the president of the United States, asking a postponement of the sales of the public lands in that section. They give as their reasons for making this request, that "there is now prevailing throughout all that section an unparalleled epidemic, that is carrying hundreds to their graves, and thousands to their sick beds, while their crops are rotting in the fields unharvested; amid such universal distress that it renders it impossible for the settlers to make the necessary exertions to obtain the means of purchasing their humble homes."

The next is a letter to the editor of the Cincinnati Gazette.

"*Lake C. H., Ia.* 13*th Oct.*, 1838.

"To the Editor of the Cincinnati Daily Gazette.

"Dear Sir.—The unparalleled drought still continues with unabated intensity. Scarcely rain enough has fallen in this section of the country to lay the dust, since the fore part of June. Wells, ponds, springs and streams, that had every mark of 'living water,' are gone, no one knows whither. Many have their water, for family use, to haul miles. Cattle are turned out upon the broad commons to seek their daily drink. Even the muskrats, that abound in such immense numbers around the head of Lake Michigan, are wandering far and wide over the dry prairies in search of their natural element.

"'The Eclipse' and the Equinox have passed, a dry storm of wind. No frost as yet has been sufficient to kill vegetation, and yet it is dried up and ready for the spreading fires that annually sweep over the prairies, the smoke of which now fills the air, and darkens the sun. A cool dry atmosphere, with high winds, has slightly improved the health of the country, but much suffering still exists.

"A most singular and remarkable fact is worthy of notice. While all the waters around have fallen, Lake Michigan has risen. The Indian tradition, long doubted, is likely to be verified, of a septennial tide in the northern lakes. It would appear as though all the surplus waters of the land had been conducted by some mysterious agency into the lake, until it is so swelled that its waves sweep with unrelenting fury over the fair fortune of many a rich owner of city property, whose thousands are permanently invested in 'Water lots.'

"A gentleman now present, whose word cannot be doubted, informs me that on a recent trip from Detroit to Chicago, he saw numerous deserted habitations upon the shores of the lakes, in some of which the water was two feet deep. And at Milwaukie, that many a lot was more suitable to sailing than walking.

"A hard fate seems to await numerous 'fine flourishing towns' in these parts. Some are submerged, and some are dried up with the great drought until they have 'not a local habitation,' though none lack a name, and some a very great one—in sound."

From the New England Farmer.

AGRICULTURAL SOCIETIES AND CATTLE SHOWS.

The cattle shows and exhibitions of manufactures in our states having closed for the season, we propose now to say a few words, of their utility, and the modes of managing them; and to suggest such measures as in our opinion would increase the advantages of our agricultural societies, and render their influence more effectual to agricultural enterprise and improvement.

We have not at hand the means of ascertaining with precision the dates in the case; but, as well as we can recollect, the first cattle show in the United States was held about twenty-four years since, under the spirited exertions of some intelligent gentlemen at Pittsfield, Mass., at the head of whom was Elkanah Watson, Esq., then of that town. The Berkshire Agricultural Society took the lead in the case, and a ploughing match was connected with their cattle show. This intelligent and highly enterprising society have continued their cattle show and exhibitions from that time to the present, with unabated zeal; and with beneficial effects of a decided and permanent character upon the agriculture of that district. Perhaps no better evidence of this can be given than in the fact, that the interest taken in this institution by the farmers of Berkshire universally was never stronger than at this time; and the exhibitions of the society, as we have been informed, were never more numerously attended nor better sustained than the current year.

The Massachusetts Agricultural Society, instituted as early as the year 1791, soon followed the lead of the Berkshire Society; and for more than twenty years, with the exception of three or four intermissions, held cattle shows and exhibitions of domestic manufactures at Brighton, open to the competition of farmers from every part of the commonwealth. Here too ploughing and drawing matches were held, which, by the liberality of their premiums, brought competitors oftentimes from a distance of fifty miles. These shows were held and managed under the direction and personal superintendence of gentlemen of the highest standing in professional and political life; and went off with spirit and effect.

These movements were soon followed by the formation of county societies in the several counties of Essex, Worcester, Middlesex, Hampshire, Hampden, and Franklin, and Bristol and Plymouth. These societies were encouraged by liberal grants from the legislature, giving to every agricultural society, formed in a county containing not less than 25,000 inhabitants, for every thousand dollars, which they should raise and permanently invest for the benefit of that society, the interest of which should be yearly appropriated to purposes of agricultural improvement, the annual sum of two hundred dollars, to be applied in premiums under the direction of the trustees of the society; provided, however, that in no case should any society receive annually more than six hundred dollars. Under these provisions a sum of upwards of four thousand dollars has been yearly given by the state to these different societies to be disbursed in agricultural premiums. This being added to the amount furnished by their own funds had formed a considerable aggregate: the sums actually offered by the Mass. Agricultural Society in premiums the current year exceeding in amount twelve hundred dollars. These county societies are now all of them in the practice of holding cattle shows and exhibitions in their respective counties. We have had the pleasure of attending as many of these as was practicable. As far as our observation extends, the bounty of the state could not have been applied to a more worthy object, nor with more success as concerns the public wealth, and the general improvement. The agricultural improvements in the state within the last twenty-five years have been immense. The plough itself has become a new instrument, in form, in lightness of draft, in ease in handling, in ease of repairs, in the execution of its work, and in the neatness of its construction. The potato-hoe, the drill seed-sower, the seed-harrow, the cultivator, the roller, the cradle, the horse-rake, the corn-planter, the thrashing-machine, the double mould board plough, the side hill plough, owe their origin and general diffusion to agricultural societies and agricultural publications. The introduction of new seeds, of most valuable fruits, of excellent esculent vegetables, of improved varieties of Indian corn, wheat, barley, and oats, this likewise is to be attributed in a great measure to the same source. The introduction likewise and diffusion of improved breeds of live stock, of the fine-woolled sheep, the long-woolled sheep, the mutton breeds, the several improved varieties of swine, the beef and dairy stock, the Devon, the Holderness, the Alderney, the Ayrshire, the improved Durham short horns, and of horses of an improved kind for the saddle and for draft, are all more or less to be ascribed to the spirit of public enterprise and improvement awakened and kept alive by these agricultural societies, exhibitions, and publications. It is indeed impossible to estimate by any exact measure what has been effected in the short space of a quarter of a century; but it meets the observing and experienced eye every where in the improved and well furnished houses, ornamental fences and embellishments, smooth and well cultivated fields, commodious barns, substantial wagons and carriages, which are to be found every where in profusion among our agricultural population. It is important to keep this spirit of enterprise and public improvement awake and active; to press the steam to the utmost limits of safety; "to speed the plough;" and to relax no efforts to advance the cause of agricultural improvement; to diffuse agricultural intelligence; to raise the character and the profession of the farmer; and thus to extend the power and the means, and quicken the spirit and enterprise by which the treasures of the earth shall be developed, the fund of human subsistence become constantly enlarged; and the comforts and reasonable luxuries of life diffused among all without stint.

The agricultural societies hold the power of doing immense good; and, as the gentlemen who have the direction of the funds of these societies have no private views to answer, but are laboring in the most disinterested manner, solely for the public good, we know them too well to fear giving offence by any suggestions, which have no other object than the public good; and which will not be submitted without a perfect respect for their public spirit and superior judgment.

We have the highest opinion of the utility of cattle shows, ploughing matches and the exhibition of agricultural products and household manufactures. They excite an emulation, which engenders no bitterness of feeling, and which prompts to the most spirited improvements. They gratify a laudable ambition to exhibit to others, what we have accomplished. They extend the knowledge of what has been done far beyond what it could be by any other means. They are the only opportunities which many farmers enjoy of seeing samples of the improved stock in the country; and of comparing it with what they have themselves. They bring farmers together to interchange friendly sympathies, and to communicate their mutual experiences. They bring men of different professions and conditions together, the professional, the literary, the commercial, the manufacturing and the agricultural on common ground, and where no jarrings of religious or political party ought to intermingle; where those who labor with the head are made to feel their dependence on those who labor with the hand; and those who labor with the hands recognize their obligations to science, to commerce, and to the mechanic arts, and find their own profession exalted and their self-respect increased by this unrestrained and mutual intercourse. These cattle shows have been the means of inducing the importation of all the valuable animals, which have been brought into our state through the liberality of gentlemen of large capital and large minds, in order to improve the stock of domestic animals in our own state. Especially, they keep the great subject of agriculture before the public mind in the light of its intrinsic, permanent, and universal importance. The well-known custom of the emperor of China at the return of every spring, to show his respect for the cultivators of the earth and thus honoring their great art by holding the plough himself in the presence of the dignitaries of the realm and of assembled thousands of his subjects, is well known. Its favorable influence upon the agricultural classes may easily be inferred; and our cattle shows, bringing together as they do gentlemen of all professions, have the same beneficial effects.

It has been, therefore, to us matter of much regret, that the Massachusetts Society has now for two or three years suspended its annual and accustomed show at Brighton. We know that it is attended with great labor to the gentlemen of the board of trustees, to get up and superintend a matter so foreign to their accustomed pursuits and habits; perhaps it is a labor we ought not to ask of them; but we believe that sixty or a hundred dollars would furnish them three or five practical men, who would gladly take all the drudgery of the management off of their hands, and get it up and carry it through in a manner honorable to the board and entirely satisfactory to the public. We know the labor is considerable, and in such case ought to be compensated; and we do not know how some portion of their funds could be more properly applied. H. C.

From Silliman's Journal.

CURSORY REMARKS UPON EAST FLORIDA, IN 1838.

By Maj. Henry Whiting, U. S. Army.

Public attention has most naturally been turned towards Florida for the last two or three years. That peninsula has been the scene of a contest of remarkable character, awakening a curiosity respecting its topography, resources, &c. which has found but scanty means of gratification. Although the first portion of the United States to be permanently occupied, (St. Augustine having been founded in 1564,) and early signalized by political revolutions, military events, and romantic enterprises, yet its history, both statistical and natural, has been but imperfectly understood by us. The Spaniards no doubt had a tolerably accurate knowledge of the interior, which was formerly somewhat extensively occupied by them. Their settlements, however, were much broken up during the insurrectionary movements which immediately preceded the transfer of jurisdiction to the United States, and the majority of them, when that transfer took place, were abandoned, under the influence of strong national prejudices, which led to a distrust or dislike of a new and dissimilar government. Much local information was thus withdrawn. St. Augustine in the east, and Pensacola in the west, with some few subsidiary plantations, were all the settlements that came into our possession. The rest was nearly an unoccupied waste. Even a knowledge of the St. John's, the grand artery of the country, had nearly passed away; so much so, that at the commencement of the present campaign (1837-8) the form, extent, and depth of its upper waters were unascertained.

The war which has lately been carried on with the Florida Indians has opened the country generally to observation, and its character will hereafter be better, if not well understood. Our troops have traversed it in almost every direction; nearly all parts have been explored, excepting the interior of the lower parts of the peninsula south of the Okachobee Lake. From the 26th degree of latitude northward, the geography may be laid down with general accuracy. Indeed, United States maps of this character are already in the hands of some of our officers, which will no doubt soon be lithographed.

The river St. John's was early entered into both by the French and the Spaniards, the rise and fall of whose establishments there form an interesting and sanguinary portion of history. At the present time (1838) there is scarcely a dwelling occupied on either of its banks fifty miles above its mouth, though many evidences of former occupancy, such as falling buildings, or fields bearing the marks of having been cultivated, are seen some hundred miles higher up. Many of these farms or plantations were abandoned by the Spaniards, at the change of jurisdiction; others were the work of Americans at a later date. But all had shared a common fate at the opening of the present contest. The Indians burnt all the buildings and plundered and massacred all the inhabitants that were not defended by a garrison, and desolation is now seen, where, a few months since, were sugar fields, cotton fields, orange groves, and many other proofs of a thriving population.

This river (St. John's) is in most respects of a remarkable character. It is unlike most if not all of the rivers in North America, having little current at any point of its course, and passing through a country, from its very source, so level in its surface, as scarcely to warrant the expectation of any stream at all. At low stages of the water there is no visible current even in the upper parts of the river, though at high stages it is visible, having perhaps a movement of one mile an hour. Below Lake George, which is more than two hundred miles from its mouth, the tides have a slight effect, and vary the current accordingly, modified, however, by strong winds. Still, the waters have not any where a stagnant appearance, and if unpalatable, they are so from causes independent of their want of proper agitation. They are uniformly of a dark color, like that of tolerably strong coffee, the bottom scarcely being discoverable even in the shoal parts. The origin of this tint may be various; decomposition of vegetable matter can contribute but little to affect a body of water so large, particularly when a considerable portion of the banks are either savannas or pine bluffs, neither likely to have much agency in this way. Lake Monroe may furnish a chalybeate tincture, as its shores abound in chalybeate earths. The lakes above may bear the same character. The waters do not lose their color when suffered to stand in a vessel and to make deposite of such particles as may be afloat in them.

The St. John's is a large river for some hundred and fifty miles from its mouth, being from three miles to a mile wide nearly as high as Lake George. Thus far it has the appearance of an arm of the sea, and in fact feels the influence of the tides. From Lake George upwards it is comparatively narrow, excepting where it dilates into lakes, and very winding, running perhaps several miles in one mile of a straight line. Lake George has been long known, and Lake Monroe, about sixty miles above, was occupied by our troops the first campaign of the present war. Thence upwards the river was to be explored at the commencement of the present campaign. It was soon penetrated through Lake Jesup to Lake Harvey, and afterwards to Lake Poinsett, about a hundred miles above Lake Monroe.

Charleston and Savannah steamboats ascended with army supplies without difficulty, at the high stage of the waters, to Lake Harvey, which supplies were sent thence by row-barges to Lake Poinsett, where the river ceased to be subservient to the purposes of transportation. This high stage was in the fall; as the winter months set in, the larger boats could ascend no higher than Lake Monroe, until spring rains again raised the level of the waters.

The banks of the river as high as Pilatka, or more than one hundred miles from its mouth, are generally elevated several feet above the water. From that point to Lake George they are comparatively low, and are probably mostly submerged at high stages of the water. Between Lake George and Lake Monroe the banks are generally high enough to be dry, excepting where savannas prevail. Wherever the pine-barrens strike upon the river, the banks are eight or ten feet high, with a substratum of shelly soil or rock. To Lake Monroe they are for the most part clothed with a growth of wood—chiefly live oak, pines, and cypress, as high as Lake George; the palmetto or cabbage tree, being largely intermixed thence upwards.

The gray moss clothes nearly all the trees upon the river, excepting the pine and palmetto. These are respected or avoided by this general associate of the trees, from some want of affinity which may not be understood. This moss is a most singular production, having a rank luxuriance little according with its kindred species. It hangs from every bough many yards in length, and wears the appearance at a distance of dingy muslin thrown with a careless grace over every part of the tree, waving to and fro in the breeze and forming a most striking embellishment of the scene; and the effect is not diminished by the presence of the tall and symmetrical palmetto, which rises up some forty or fifty feet perpendicular, like a perfectly wrought column, surmounted by a capital of most appropriate beauty. The moss never throws its foldings over this handsome tree; as we have before remarked, the pine is equally avoided by it. This capricious forbearance with respect to these two kinds of trees, introduces a beautiful variety into the river scene. Where the banks are high and sandy, the pine prevails; where they are low and wet, the cypress—"the melancholy cypress." The live oak, and other miscellaneous trees, prefer the banks of an intermediate character, as also the palmetto. The cypress seems to exclude all associations; no other trees mingle with it, or if they happen to start up along side they are soon overshadowed above by the spreading tops, or crowded out by the cone-like bases below, which last leave only room for the thousand "knees," or sharp excrescences, from one to several feet high, which shoot up like so many dwarf pinnacles.

Ascending the river, which is constantly winding and shifting the point of view, wherever the cypress permits, there the moss is seen in all its sweeping luxuriance. As these trees spring from nearly a water level, and grow to about an equal height, their flat and spreading tops present nearly a horizontal line, where the green appears in all its depth and freshness. Thence, however, to within a few yards of the ground, the folds of moss, like ample curtains, conceal nearly all from view, leaving the trunks exposed below, which are covered with a whitish bark. This aspect may prevail for half a mile, when the banks may rise and become covered with the live oak, whose angular and scraggy arms give a new appearance to the moss, which is still as luxuriant as on the cypress. But the outline above is far different here. Palmettos perhaps raise their graceful heads above the oaks in striking contrast with their associates; or perhaps the pine may show in the barren beyond; while over all is the clear azure of the sky, always in Florida

"So purely dark, and darkly pure."

These changeful beauties, combined with the occasional sight of a wild orange-grove, with its golden fruit bespangling the foliage, altogether render a trip up the St. John's delightful in a high degree.

The ash, poplar, swamp oak, &c., which line the banks of a part of the upper St. John's, drop their leaves during the winter months, unlike all the other trees to which we have been alluding. But these trees would seem to be deciduous, to exhibit more plainly the verdant parasite which attaches itself to most of their branches. In passing up the river for the first time, the uninstructed gazer is surprised and puzzled to see on all these trees a tuft of evergreen, while the branches in general are stripped of their foliage, until informed that it is the mistletoe, which, having attached itself thus to a foreign stock, continues to smile in verdure, while its supporter is standing in gloomy nakedness. The mistletoe bough is always of a rounded form, varying in size from a few inches to thirty or more in diameter. The seeds, which are said to be winged, have a gluten surrounding them, which enables them to attach themselves where they alight and at once to draw forth nourishment as if fixed to a parent stem. The *nullius filius* of the forest, it is adopted by the first tree to which it flies for protection and sustenance.*

Sulphur springs are very abundant on the upper parts of the St. John's. They bubble up like *jets d'eau.* In passing up to Lake Monroe, there is one a few miles below, which attracted, among others, the notice of Bartram. An inlet on the right bank is seen, nearly of the width of the river, which at once attracts the eye, by the contrast between the color of its waters and that of the river. Two pieces of lumber, placed at right angles with each other, one of mahogany and the other of yellow pine, could not be more dissimilar. And the liquid line of separation is almost as distinct as it would be in the supposed case. The St. John's has here, as elsewhere, its coffee-like hue, while the waters of the sulphureous inlet are as transparent as the air, the fishes swimming in them being nearly as discernible as the birds flying over their surface. The alligators, diving, as usual, at the approach of a boat, when they happen to take refuge in this limpid inlet, continue to struggle downwards in apprehension, as if they felt that it did not afford the usual refuge.

Ascending this inlet several hundred yards, it is found to terminate in a well head or basin, of some thirty feet diameter, with high banks, in the centre of which there is a permanent turmoil of the waters, as if a fountain below threw up its contents with much force. Rowing the boat upon this agitated spot, it was with difficulty kept there in its position, against the efforts of the ebullition to throw it off. A strong odor of sulphur fills the air around, and the taste of the waters is equally sulphureous.

Above Lake Monroe, wide-spread savannas become prevalent. They form the main body of the section of country through which the St. John's flows, and are so slightly inclined, that its course is extremely tortuous, the bends having more the shape of a horse shoe, than of a segment of a circle. The immediate banks in these savannas are somewhat elevated above the level of the waters, as the growth of a wild cane indicates, but the greater portion of them bear a tall, rank grass, which shows that it is often inundated, and that the soil is constantly saturated with moisture. Lakes George, Monroe, Jesup, Harvey and Poinsett, are fine sheets of clear water, of no great depths, but generally free from aquatic vegetation. They all abound in fish and wild fowl.

Fort Taylor, (a mere stockade like all the other forts in Florida of recent origin,) which was built a few miles above Lake Poinsett, three hundred and fifty miles or more from the mouth of the St. John's, is the highest point to which the army boats ascended. Above that post, the river narrowed and shoaled, so as to become useless for all purposes of transportation. The army there took its course southwardly, reaching the head waters of the St. John's, some seventy or eighty miles S. S. E. The source of this river has been in question up to this time, having been supposed to be connected either with the everglades or the sea. Both of these suppositions are now at an end. The strip of land between the coast and the St. John's, as far south as Cape Florida, has been sufficiently explored, to determine the fact, that it has no channel connexion with the sea in that quarter; and it has been equally ascertained, by various army movements, that it is also without a like connexion with the everglades or the lakes, to the west and south-west. In rainy seasons, when the water overspreads nearly the whole country, the St. John's may be connected in a diffused way with both sides. Fall and spring rains, when they come, elevate the river sometimes many feet, as would appear by marks on the banks. The last two or three seasons, the difference has been from two to three feet. The low stages are, at midsummer and midwinter and when the periodical rains happen to fall, or are only moderate, the subsidence must be very great. It has been remarked by the Indians, that all the waters occasionally drain out. This may be an exaggeration; but such a result, nearly to the extent expressed by it, might easily be supposed to follow a year of drought, the St. John's being evidently dependent for its supply on the tides below and the rains above.

The interior of Florida, south of Lake Monroe, was scarcely known, until the present war. It was assigned by conjecture and common report, to the "everglades," an indefinite and comprehensive term, which means neither land nor water, but a mixture of both. These supposed everglades, have been much circumscribed by late examinations. They have lost, at least, one or two degrees of latitude. Okachobee Lake, a body of water of some forty miles in diameter, and of a decided lake character, and the lands east and west of it, can no longer be thus classed. The lake south of this, reported to be still larger than Okachobee, called by the Indians, Pai-hai-okee, or grassy lake, may prove, on examination, the true everglades. But it is now about as probable, that even this, their last hold, will be found to partake of the general character of that part of the peninsula, and that land and water will then have its usual divisions, so far as a sandy country of unusual flatness permits. The name which the Indians have given the lake, shows that it must be generally so shallow as to allow grass to predominate; rendering it probable, that it has a less decided lake character than the lakes above.

It was until lately taken for granted, that the interior of Florida was without any eminent parts, but the army movements have opened to obser-

* This is a mistake. The seeds of the mistletoe are not *winged*, or capable of being conveyed to other trees by the winds. But their diffusion and propagation are as well secured by another curious and admirable provision of nature. The seeds are enclosed in berries, filled principally with a glutinous pulp, and which form food for certain birds. In eating the mistletoe berries, the glutinous matter and the seeds contained, which adhere to the outside of the bird's beak, are wiped off, on any branch on which it afterwards perches. By this operation, the seeds are stuck to any other, and often to distant trees, where they sprout and take root; and the manner of the deposite is the cause why the mistletoe more often than otherwise is rooted in the lower side of the limb, as a bird most conveniently wipes its beak on the lower side of the branch on which it stands.—Ed. Far. Reg.

vation, some sandy ridges or hills of considerable elevation. These are not far from that central region where the waters diverge to different sides of the peninsula. The course of the various streams which take their rise within these central parts, marks out the character of the slope, running north-west, south-west, south-easterly and northwardly. The Onithlacoochee, Pease Creek, Kissimmer, St. John's, and the waters emptying into the Indian River lagoons, all illustrate this central elevation, and general inclination towards the coast.

One of the striking features of the coast of Florida, is the lagoons, as they are termed, or long and narrow bodies of water, separated from the sea by a strip of sand, generally not more than a mile or two wide. They are connected with the sea here and there by inlets, which are made and kept open by the out-rushing or in-rushing tides, as they happen to prevail. The outward current is that which chiefly prevails, from the most natural causes. Accumulations from rains, must give a great preponderance to the inner waters, which, however, may, in the course of a dry season, drain out to a level with the outer waters, when the drift of a storm blocks up, at least for a time, the usual passage, and so it remains until the balance of force is turned by new rains.

This alternate operation of counter causes, explains the fact well known by those who frequent this coast, that these inlets are at one time very accessible, and at others, nearly or quite closed up. These lagoons extend from above St. Augustine to Jupiter inlet, a stretch of three or more hundred miles, with but a few miles interruption by land. Their common depth is several feet, though they all are traversed by shoals or bars, which reduce their navigable facility to about three feet. These shoals, however, could easily be made passable for useful purposes. It has been proposed to connect the river St. John's by a canal with the Matanzas river, separated by about ten or fifteen miles; the Matanzas with the Halifax, twice that distance, perhaps, apart. Between the waters of which the Musquito inlet is the embouchure, and those of the Indian River, there is only a narrow neck of about half a mile. Such a project would open an interior navigation from Charleston to Jupiter inlet; and below Cape Florida it is well known that a practicable and sheltered channel runs around the peninsula, within the "keys."

The mangrove tree is a conspicuous embellishment of the Indian River lagoon. Being of an aquatic character, these trees, by a happy provision of nature, are radicated to suit their thrifty habits, not unlike the long-legged species of birds which are fitted for the water; they stand with their trunks lifted several feet in the air, sending out roots from that elevated point, like so many bow-legs, to seize the earth or water below, with a base often as wide-spread as the branching head above. Then, again, as if these roots could not drink moisture enough to satisfy their cravings, each branch sends down many a slender tube perpendicularly to the water, like so many syphons to draw it up. The foliage is of the brightest green. Altogether, a mangrove thicket is a most attractive object to the eye. These thickets sometimes shoot out a spur into the lagoon, resembling just above the water a fisherman's weir-net, but surmounted by a most redundant foliage, and almost closing up the channel.

The bars at the mouths of the lagoons are an obstruction to the commercial facilities of Florida. The entrance to St. Augustine harbor is perhaps the best on the coast, and, with proper attention to the tides and winds, is safely practicable for vessels of light draft. The drift of the ocean, which in this quarter is strongly charged with alluvion, heaps up the sands along the coast, constantly changing their position, with, probably, a gradual augmentation. The inlets would share the common fate, and be closed up, if it were not for the outsetting currents, arising either from the tides, or the accumulation of waters within. These causes, with partial exceptions, keep open a channel, but cannot preserve it in one place. The bar off St. Augustine has widely shifted, being now nearly one-half the points of the compass to the north of its position, within the memory of living pilots. Those of the more southern inlets are less practicable, excepting that of the Musquito. The channels are known only to those who are habitually upon them. A fearful looking surf is always coursing over them, when a wind is blowing with freshness, which renders them formidable to strangers, while those who are accustomed to them, pass through it with little real hazard. The evil, however, is a great one, and apparently irremediable.

The rivers of Florida, though of no great length, are, generally, of a most convenient depth. The banks are bold and firm. Those which empty into the lower part of the St. John's, are fitted for any craft that comes into the main river, or have no impediments in the way, excepting what arise from fallen trees. There is no current to change their character, which belongs to a level country.

The botany of Florida was early examined by the Bartrams, and Audubon was some time among its birds, which are rich in number and variety. Many anecdotes are told of the latter, showing the patience with which he kept his station in swamps and marshes, in order to ascertain the habits of the feathered creatures there, in spite of musquitoes, reptiles, and other intolerable annoyances. Doct. Leitner, who was killed in a skirmish with the Indians, this campaign, (1838,) is said to have been a skilful botanist, and an ardent votary of science. Accompanying a portion of the active force, he would have had uncommon opportunities for observing the plants of the southern interior, which, probably, came little within the scope of the Bartrams, whose investigations were mostly, if not altogether, on the river St. John's and the coast. He had already made considerable advances towards the object he had in view, with a most flattering prospect before him, when he fell in the honorable performance of his duty.

The orange tree has been extensively cultivated in Florida, since its first occupation. The Seville or sour, and bitter-sweet orange, are apparently indigenous to the country, as many groves of both are now found flourishing, where no labor of man would seem to have placed them. The China, or sweet orange, is probably an exotic. These were found, not only around nearly every house in the country, but occupying a part of nearly every garden in the towns. They were an important article of commerce. The oranges of Florida excelled all others in the northern markets. More than two millions, were annually shipped from St. Augustine alone. One tree there is said to have produced six thousand in one year. But this staple of the country was cut down in one night, in 1835. A severe frost occurred in the time of Bartram, (1765,) which killed the lemon, citron, and other tender trees, but only partially injured the orange. There were trees standing in 1835, more than a century old.

This calamitous event, besides destroying one of the principal sources of revenue of St. Augustine, divested the place of its chief ornament. Each lot became, as it were, denuded of its drapery, which had been thrown over every building, high and low, giving them all a borrowed beauty. A person who was absent at the time of the frost, in revisiting the place, could scarcely recognize the most familiar scenes, their aspect was so entirely changed. It takes about seven years to renew the orange tree to a bearing state.

Cotton and sugar grow well in Florida, but silk will probably be the staple of the country after a few years. The mulberry tree, multicaulis, &c., grow there with a vigor and luxuriance that have no parallel in the United States. More than eight months in the year afford a fulness of food for the worms.

The soil of Florida wears a forbidding aspect. Sandy barrens form the principal part of the surface. Hammock land, that which bears the oak, maple, and other "hard woods," and which are the richer and more productive parts, constitutes but a small proportion. But the sands of Florida are but in part siliceous. They are probably for the most part comminuted shells or lime-stone. Hence they have a degree of fertility which often surprises those who undertake their cultivation. The surface, however, is so level, that it is liable to the extremes of drought and inundation. In riding from the St. John's to St. Augustine, a distance of eighteen miles, the road will be found, after a moderate rain, one-half or two-thirds under water, which is carried off more by evaporation than by subsidence; and this is a sample of the country in general.

The yellow pine, pinus palustris, is a conspicuous tree in Florida, both on account of its lofty symmetry, and its adaptation to many useful purposes. It affords tar and turpentine in inexhaustible abundance, and is an equally inexhaustible material for lumber. Whether it be the only growth the soil can yield, or merely a pre-occupant, as in many other parts of the country, giving place, when removed, to a species of hard wood, is, perhaps, not yet ascertained. It is propable, however, that when this tree shall be cut down, and fires, scorching the whole face of the country, shall cease, the growth of the forest lands will assume a better aspect, and that the soil will improve in a corresponding degree. It is the fallen tree of this pine, which furnishes the Indian with his "light-wood;" a source of comfort and convenience that strongly attaches him to the soil which produces it. The fuel formed from these prostrate trunks, is at hand on every spot, and is easily ignited, making, in all weathers, a bright and durable fire. The nights of Florida are almost invariably cool, and the facility with which the Florida Indian can temper their chilliness, by means of this ready and combustible wood, is a conspicuous item in the privileges of his life, the great design of which is to attain desirable objects with the least effort. Our troops, in the late campaigns, have been equally indebted to it for many a comfortable encampment, as, even in the midst of heavy rains, a brilliant fire might be kindled, which, with due care, no rains could extinguish.

The hammocks at present are generally secure from encroachment from the barrens, being mostly covered with a dense growth of trees, which preserves them from change. But, whenever the time arrives in which they shall be cleared up, and become exposed to external influences, it is not unlikely that the surrounding barrens, clothed in a soil of such levity as to be acted upon by winds and rains, will gradually overspread these comparatively small spots on the surface of the country, and reduce nearly the whole to one general character.

The waters of Florida abound in fish. Even the upper parts of the St. John's afford a large supply of very tolerable quality. But the lagoons of the coast have not only an abundance of the finest fish, but also of the finest oysters. The oysters of Indian river are surpassed by none, in size or quality, on the Atlantic coast. Want could never approach the inhabitants of that region.

The present war, during which the Indians have been too much harassed to attend to seed-time or harvest, has turned attention to the class of indigenous esculent vegetables, which, by their spontaneous abundance, have, through the extremities of this period, afforded them ample means of subsistence. The most conspicuous among these are the red and white coonta roots. The first is the China-brier, or *Smilax china*, a vine of great thriftiness, spreading sometimes over the space of more than a hundred feet, with roots like a large, long and irregular potato. The white coonta is the *Zamia integrifolia*, which has a full tap-root, rounded with the symmetry of a boy's top. The leaves are large and fern-like, forming, when the seed-bud is in its fulness, a handsome plant.

Both of these roots are grated or bruised by the Indians, and the starch separated, by frequent changes of water, from the fibrous or woody parts, as also, in the white coonta, from a poisonous quality which is combined with it in its natural state. The flour of the latter has the look and feel of arrow-root, and is equally nutritious and well suited to weak stomachs. The flour of the China-brier is of a reddish hue, and more easily obtained than the white coonta.

These two important articles of food are found in abundance, the one or the other, in most parts of southern Florida; the China-brier in nearly all the hammocks, and the Zamia in most of the barrens along the coast lagoons. Thousands could subsist upon them, with only the labor necessary to gather the roots and prepare the flour. Previous to the war, one or two persons were established near Cape Florida, who manufactured the white coonta in large quantities for shipment. Medical men often prefer it, for hospital purposes, to the arrow-root.

The palmetto is often called the cabbage-tree, from its containing an edible substance within its top, which somewhat resembles a cabbage—more in look, however, than in taste, which is not unlike that of a raw chestnut. Where the fan-shaped leaves of this beautiful tree put out at the top, is found unfolded a pith, forming about one-third of the diameter of the trunk, and about 12 or 15 inches long, which is of an eatable quality, particularly when boiled, or preserved as a pickle. It is true, a tree some half-century old might be sacrificed to the attainment of a single meal; but these trees are abundant, and no doubt have often afforded one to a roving Indian, who sat down hungry and unprovided beneath their shade.

But the necessities of the war now going on, have opened a new resource to the Indians, or which, at least, does not appear to have been used by them in more abundant times. This is found in the root of the *saw-palmetto*, a singular species of most common vegetation in Florida, which overspreads nearly every pine-barren, covering it like a vast reticulated carpet. In passing over these barrens, the palmetto leaf is seen shooting up from the ground in great luxuriance, forming, as is found on close inspection, the termination of a recumbent cabbage-tree, several feet long, and probably half buried beneath the surface, or deciduous vegetation. Lying constantly on the ground, it never acquires the bony hardness of the exterior coat of the upright cabbage-tree, but is covered with a fibrous hairiness, which gives it almost the softness of silken plush, prevailing through every fold, to the very heart, excepting within a few inches of the end, where is found a nutritious pith, smaller than, but not unlike, that of the cabbage-tree. This is bruised into meal, and made subservient to the purposes of food. These roots spread, as we have before remarked, over nearly every barren; and, since a portion of them is convertible into food, there can be no limit to the spontaneous subsistence of those who frequent them. The leaves or foldings of this root are thin and pliable, several inches long, and three or four wide, and are worked into many articles of ornament and use.

There is also found in Florida a wild potato, of tolerable quality, and much wild fruit. Game of all kinds is abundant, and wild fowls are numerous on every stream and lake. The Indians, in Spanish times, were accustomed to herd cattle largely, and at the commencement of the present war, they are said to have had thousands.

From this enumeration of the articles of food which present themselves spontaneously to the wants of the Indian, it will be seen that they are little dependent on care, foresight, or labor, for subsistence.

The mineralogy of Florida is scanty. The rocks found in situ are all calcareous, though siliceous boulders, of a small size, are occasionally seen, and nodules of hornstone are here and there mingled with the limestone, which elicit sparks, and are sometimes used by the Indians for flints.

The geology of Florida presents many interesting features; but it has as yet been examined with little attention, warranting few definite conclusions. The coast, as far as Cape Florida, is alluvial, a seeming mass of comminuted shells, resting on a rocky formation, composed also of shells, more or less broken and abraded. From Cape Florida, the formation is mostly coralline, the Keys being of that character. The shells around the Keys are found in nearly a perfect state. Take up a handful at random, and it will exhibit little else than fragments of coral and univalves, generally of a small size, and diminishing almost to a point. As high as Indian River Inlet, the beach is still formed of shells, though less distinct and perfect in their form, mingled with some sand; while about Cape Carnaverel the sand predominates, until shelly fragments almost disappear to the naked eye. Still, it seems probable that the whole beach is of a calcareous character.

The coquina rock (as the Spaniards called it) is a formation found in the spits of sandy land which separate the lagoons near the coast from the sea. It has been quarried in Anastasia island, for more than a century, affording a material for structures of all kinds in St. Augustine, worked with uncommon facility, and of a durable character. A large fort, of Spanish construction, at that place, is of coquina. In latitudes where there is little or no frost, it is, perhaps, the best material that can be used in fortifications; being firm enough to sustain the form of any work, and receiving a shot like a plastic mass, exhibiting no fracture, and throwing off no splinters.

The quarries near St. Augustine are generally about ten feet deep. The profile of the strata, as presented to the eye there, exhibits, first, a superficial covering of vegetable mould; next, a stratum of shelly fragments, quite small, and without any distinctness of character, with no cohesion. This stratum varies much in thickness, according to the undulations of the surface, being generally from two to three feet. The next in the descending series is a stratum of several inches thickness, composed of similar shelly fragments, but united in a mass by some cement. Then intervenes a stratum of sand, an inch or two in thickness. Immediately below this sand is a stratum of shelly rock, between two and three feet in thickness. This stratum is formed of shells in various states, the upper several inches being much like the stratum above, that is, of small and indistinct fragments, when, for several inches more, it assumes a new character, many of the shells being perfect in their outlines, and only much abraded, and most of them of a size to give some clue to their species. The interstices in this portion of the mass are large in proportion to the size of the shells, and the cement which holds them together is hardly visible. Bivalves, cockles, of the cardium species, predominate, while here and there is found a conch of large size, as also oyster fragments. Some of these conchs are several inches in length, though much worn. This coarse and comparatively unbroken deposite has a substratum, with which it is equally closely joined, like that superimposed. A thin stratum of sand next succeeds; and then a third stratum of shelly rock, about two feet and a half thick, the component parts of which are in a state rather more comminuted than any lying above. This stratum is likewise of a more solid and uniform character than its associates, and gives the largest blocks for building purposes. A sandy stratum is found below this, and, so far as an examination has penetrated, a coquina formation descends no lower.

All these strata are firm concretions, their component parts being obviously conglutinated by a calcareous substance, which holds them well together. This foreign substance, or cement, is quite visible in the finer formations, though little seen in the coarser. Taking up a piece of the latter, the cause of cohesion is apparently so slight, that one is surprised that the mass does not crumble at a touch.

It is a common conjecture that the coquina is of recent formation, and that causes are still operating to produce it. This conjecture has some apparent and plausible grounds. It wants, however, the support of deeper investigation into the character and force of these causes. Fragments have been constantly heaping up on the coast, portions of which have been long lying in a quiescent state, without exhibiting any evidences of a change, or a tendency to one, particularly of a change from a loose to a concrete state. The upper stratum of the quarries we have been describing, would be likely to assume the character of the strata below, if such a change were in progress. But the century, during which it has been subject to observation, has witnessed no alteration. The fragments all lie in a separated state, without showing any signs of cohesion.

It has been surmised, that the animal matter of the shells might have furnished the element of cohesion. But this surmise would seem to be at once disproved by the condition in which the shells were found, when the concretion took place. It is evident that they must have been subjected to a long and severe process of attrition and contusion, previous to that event; such a process as must have widely separated all animal matter, from its former covering. Besides, there is no reason for supposing, that this animal matter, even if it had existed in connexion with the shells at the time the rocky formation occurred, could have produced the effect assigned to it.

A more probable conjecture is, that the shells themselves, by some chemical exertions or agency, which operated in connexion with their partial dissolution, furnished the bond of union among the fragments, though not in a way that leaves the same agency still in operation. These different strata are evidently so many distinct deposites, probably at different and distant periods; broken shells thrown up or spread over a certain space, and no doubt converted at equally different and distant periods into solid masses, either by sudden or gradually operating causes, ceasing with their effect. Such a hypothesis is in harmony with our notions of other formations of rock.

There are appearances of shelly formations on the St. John's, particularly the upper parts of it, but the shells are of a different character. Scarcely a bivalve is seen on or near that river, either loose, or in rocky connexion. The prevailing shell there, is the helix, while univalves are as rare in the formations on the coast. The soil at Volusia and Fort Mellon consists of half shells, which are generally perfect in their shape, the defects evidently arising rather from decay than abrasion or contusion.

The limestone does not show itself on the coast, nor on the St. John's until you reach Lake Monroe, where it is intermixed sparingly with shells. On Black Creek, west of the St. John's, a porous, rotten limestone appears, and this is said to be the character of the rock formations throughout the western part of the peninsula. Hence the many "surth-holes," deep and (some of them) unfathomable orifices in the earth, which appear in these regions, and the disappearance of streams for many miles beneath the surface of the earth, while others come forth in all their fulness at once.

The climate of Florida, during the six or seven months from October is truly delicious. The frosts are generally few and slight, leaving vegetation its verdure, and flowers their bloom, throughout the year. Such frosts as kill the tender trees or shrubs are of rare occurrence. Rains occasionally prevail during the winter months, but more commonly during the latter part of summer. Our troops have now been operating during three winters. Two of them have been decidedly dry. The first was rainy.

By a loose diary, kept in Florida, since the last October (1837) and continued through two hundred and fourteen days, more than one hundred and fifty of them, were decidedly clear and pleasant days; about forty somewhat cloudy or foggy; and about twenty rainy, but of these nearly one-half were single rainy or showery days, leaving only about ten which were of a rainstorm character. Musquitoes have bitten, and frogs have peeped throughout the whole time, though not always in the same numbers or with the same spirit.

It is perhaps a common impression, that there are some formidable animals and many venomous reptiles in Florida. The alligator is a clumsy, timid animal, never, it is believed, the assailant, unless it mistake a swimming boy, for its common prey. Scorpions, snakes, lizards, &c., are common upon the barrens, and our soldiers, in sleeping on the ground, often came in contact with all of them, and were often stung by the former, generally with unpleasant, but never with fatal consequences.

Invalids have long looked to Florida as a refuge from the northern winter, and during the disturbances of the last few years, St. Augustine has necessarily been the only place of resort. But when peace shall be established, and the St. John's re-occupied, that river will present many places of great attraction to the infirm and pulmonic.

From Loudon's Gardeners' Magazine.

OF THE ANALOGY BETWEEN PLANTS AND ANIMALS. BY J. A. W.

Many persons buy a plant and plant it in their garden, as they would purchase a piece of furniture and place it in a room, and fancy that the one requires no more after-care than the other; but, when they understand something of the nature of a plant, and of the manner in which it obtains nourishment; and when they perceive how cultivation operates on it; they will take a degree of interest in its growth and developement, that a person totally ignorant of these subjects can scarcely form an idea of.

Plants are organized beings, that, like animals, depend for their existence on nourishment, warmth, air, and light. Their nourishment they derive from the soil, their warmth and air jointly from the soil and the atmosphere, and their light from the sun. As all men may be presumed to know something of the nature of animals, perhaps the easiest way of giving some knowledge of plants to those who have hitherto paid little attention to the vegetable kingdom, will be, by first pointing out the principal points of analogy between plants and animals, and next noticing the structure and functions peculiar to plants.

Plants resemble animals in having an organic structure endowed with life, and in requiring nourishment to enable them to continue to exist. They absorb this nourishment through the small tubular fibres of their roots, in the same way as animals do theirs through the small tubes called lacteals, which convey it from their stomachs. Plants differ from animals in being fixed to one spot; in having the principles of vitality and reproduction diffused over every part, and in thus being propagated by division, as well as by ova, or seeds; in being without a brain or nervous system, and, consequently, incapable of feeling; and in light being as necessary to their existence as air is to that of animals.

The soil in which a plant grows is as essential to it as the stomach is to an animal. Food, before it can be absorbed into the system, must be reduced into a pulpy mass, consisting partly of chyle; or nutritious matter, and partly of refuse. This process, in regard to animals, is performed in the stomach, and is called digestion; and, when it is finished, the lacteals suck the chyle from the mass, and convey it to the lungs, where it is assimilated to the blood, and thence is distributed through the frame.

The food of plants is rotted, (a process similar to digestion) in the soil; and is there brought, by the addition of water and gases, to a sufficient state of fluidity to enable the spongioles of the roots to absorb from it the part necessary for the nourishment of the plant. It is then carried up to the leaves, where it undergoes a process similar to that to which the chyle was subjected in the lungs, and becomes true sap, which contributes to the growth of plants, as blood does to that of animals.

When a plant or an animal is in a state of disease, no application to the leaves and branches of the one, or to the external members of the other, will be of much use, if the soil or the stomach be neglected. The stem and branches of a plant, and the external members of an animal, may be injured, mutilated, and even diseased; but, if the soil and the stomach be invigorated, and placed in a healthy state, the whole plant or animal will soon recover from the injuries it has received, so as to perform all the functions necessary to its existence. The first step, therefore, in cultivating or in improving plants, is, to improve the soil in which they grow.

In all vertebrate animals, there is a part at the back of the neck, between the spinal marrow and the brain, where a serious injury will occasion immediate death. There is a corresponding point in plants, between the root and the stem, which is called the neck, or collar; and at this point plants may be more readily injured than any where else. Most plants, also, may be killed, by covering this point too deeply with soil. In all seedling plants, this neck, or vital point, is immediately beneath the seed leaves; and, if the plant be cut over there when in a young state, the part which is left in the ground will infallibly die. In old plants, however, and particularly in herbaceous plants, which have creeping stems, and in various kinds of trees and shrubs, the roots, after a plant has attained a certain age, become furnished with buds; and, when the plant or tree is cut over by the collar, these dormant buds are called into action, and throw up shoots, which are called suckers. No sucker, however, is ever thrown up by the roots of a plant cut through at the collar while in its seed leaves. The branches of a tree may be all cut off close to the trunk, and the roots also partially removed; but, if the collar remain uninjured, the plant, in a suitable soil, and under favorable circumstances, will throw out new roots and shoots, and, in time, will completely recover itself.

There are some plants of the herbaceous kind, (such as the horse-radish, for example,) that do not suffer, even if their collar should be buried two feet or even three feet; but by far the greater number of plants, (such as the hepatica, the common daisy, the common grasses, &c.,) are killed by having the collar covered two or three inches; and nothing is more injurious to woody plants, whether large or small. It is easy to destroy a large tree by heaping up earth around the base of its trunk; and easy to prevent a small one from growing, by lifting it, and planting it six inches or one foot deeper than it was before. Hence the great importance of not planting any plant deeper in the soil than it was before taking it up. The cause why plants are so much injured by burying the collar has not, as far as we know, been physiologically explained; but it probably proceeds from the want of the action of air on the collar, or on that part of the stem which is immediately above it; or from the pressure of the soil upon that vital part.

The next point of analogy between plants and animals, which it may be useful to notice, is that between the lungs and the leaves. An animal can no more live without its lungs than without its stomach. The stomach, as we have seen, is necessary for the turning of food into chyle, and the lungs for turning that chyle into blood. Now, a plant can no more live and grow without leaves, than an animal can without lungs. The use of the lungs is to expose the chyle to the action of the air, which they decompose, so that its oxygen may unite with the chyle, and thus change it into blood. The leaves of plants, which act to them as lungs; not only decompose air, but light, in the process of elaborating the sap; and, hence, plants can no more live without light, than without air or food, as light is necessary to turn their food into sap, or, in other words, to bring it into the proper state for affording them nourishment. Hence, in the culture of plants, the great importance of light. An important difference, however, between the circulation of the sap in vegetables and the blood in animals, is, that the former have no heart.

Plants and animals agree in requiring a certain degree of temperature to keep them alive; and the warmth of this temperature differs greatly in the different kinds both of plants and animals. Hence, the constitutional temperature of any plant to be cultivated being known, that temperature must be maintained by art; either by a suitable situation in the open air, or by its culture under a structure which admits the light, and is capable of having its atmosphere heated to any required degree. The temperature which any plant requires is ascertained by its geographical position in a wild state; making allowance for the difference produced in the habits of the plant by cultivation.

Plants agree with animals in requiring periodical times of rest. In animals, these periods are, for the most part, at short intervals of not more than a day; but, in plants, they are commonly at long intervals, probably of a year. In warm climates, the dormant period of plants commences with the dry season, and continues till the recurrence of the periodical rains which are peculiar to the tropical regions. In temperate countries, the dormant season in plants commences with the cold of winter, and continues till the recurrence of spring. When plants are in a dormant state, they commonly lose their leaves, and, consequently, at that season, they are unable to make use of the nourishment applied to their roots; and hence the injury done to them when they are stimulated with nourishment and warmth, so as to occasion their growth during the period at which they ought to be at rest. Hence, also, arises the injury which plants receive, and especially bulbs, if the soil about them be kept moist by water when they are in a dormant state. Plants having no feeling, in the common sense in which the word is used, can neither experience pleasure nor pain; but they resent injuries, either negative or positive, by slow growth, or by becoming diseased. By their being fixed to the spot where they grow, they necessarily depend for their food, heat, air, and light, on the circumstances peculiar to that spot; and, hence, to increase their growth beyond what it would be if left to nature; additional food must be brought to them, and the warmth, airiness, and lightness of the situation increased. Hence, what is called vegetable culture; which consists in stirring the soil, adding manure to it, regulating the supply of water by draining or irrigation, sheltering from the colder winds, and exposing to the direct influence of the sun's rays. If we imagine any one of these points attended to, and not the others, the plant will not thrive. Stirring the soil, and mixing it with manure, will be of little use if that soil be liable to be continually saturated with moisture, either from its retentive nature, from springs from below, or from continued rains from above; or if it be continually without, or with very little moisture, from its porous nature, the want of moisture in the subsoil, and the want of rain and dews from the atmosphere. Improving the soil without improving the climate, (that is, without communicating a proportionate degree of warmth and light,) will increase the bulk of the plant, but without proportionately bringing its different parts to maturity. For example, we will suppose two plantations of trees planted at the same time, on similar soil, and in the same climate; that in the case of the one plantation the soil was trenched and manured, and in the other not; and that the trees were planted in equal numbers in both plantations, and at the same distances. The trees in the prepared soil would grow rapidly, and in the unprepared soil slowly. After a certain number of years (say twenty), we shall suppose both plantations cut down; when the timber produced by that which had grown slowly would be found hard, and of good quality; while that produced by the plantation which had grown rapidly would be found soft, spongy, and, when employed in construction, comparatively of short duration. The reason is, that in this last case the rate of nourishment to the roots exceeded the natural proportion which nature requires in plants, between the supply of food to the roots, and of light and air to the leaves. Had the trees in the prepared soil been thinned out as they advanced, so as never to allow their branches to do more than barely touch each other, they would have produced a great deal more timber than the trees on the unprepared soil, and that timber would have been of equal firmness and duration with timber of slower growth. It ought, therefore, to be strongly impressed on the minds of amateur cultivators, that though nourishment of the root will produce bulk of the top, or, at least, length of top, yet that it is only by abundance of light and air that quality can be secured.

One very remarkable point of difference between animals and plants is, that which has been before alluded to, the much greater provision which nature has made for the propagation of the latter than of the former. Plants not only produce immense quantities of seeds, which are distributed by the winds and waters, by animals, and by various causes: but they extend themselves by shoots, which run on or under the surface of the ground, as in the case of the strawberry, the raspberry, &c.; and they produce buds, each of which, by human art, can be rendered equivalent to a seed, either by planting it (with a small portion of the plant from which it is taken) at once in the ground, or by inserting it in another plant of the same family. Hence, the great facility with which plants are multiplied both by nature and art; with the exception of a few, in which the process of propagation by artificial means is comparatively difficult.

Another remarkable difference, also before alluded to, between plants and animals is, the absolute necessity of light to plants during the whole period of their existence. There are many animals of the lower description, such as worms, to which light, so far from being necessary, is injurious; and there are instances of even the more perfect animals having lived for several years without the presence of light, either natural or artificial. Light is not necessary for either the functions of the stomach, brain, or lungs, in animals: but in plants, though it is equally unnecessary for the functions of the root and the collar, it is essentially so for those of the leaves; and the leaves are necessary to the elaboration of the sap, and, consequently, to the nourishment of the plant. A plant, therefore, from which the leaves are continually stripped as soon as they are produced, soon ceases to live. Small and weak plants, from which the leaves are taken off as they are produced, will die in a single season; and this practice, continued for two seasons, will kill, or nearly so, the largest tree. If, instead of stripping a plant of its leaves, the leaves are produced in the absence of light, and light never admitted to them, the effect will be precisely the same. Seeds germinated, or plants struck from cuttings, in the dark, will not exist a single season; nor will trees, or tubers, such as the potato, placed in an apartment from which all light is excluded, live more than two seasons. Hence, the importance of light to plants can scarcely be overrated; for, while it has been proved that plants, even of the most perfect kind, will live for many months, or even years, in glass cases in which very little change of air has taken place, there is no instance of plants, even of the lowest kind, such as ferns and mosses, living for any length of time without light. Without light, there can be no green in leaves, no color in flowers, and neither color nor flavor in fruits.

Plants agree with animals in having a sexual system; but they differ from animals in having for the most part both sexes in the same individual. In the improvement of plants, as in the improvement of animals, the sexual system is a powerful agent; and what is called cross-breeding is employed with as great advantage in the vegetable as in the animal kingdom. It is remarkable, that the general laws and results by which the process of cross-breeding in both kingdoms is regulated are the same: the two parents must be two varieties of the same species, and their qualities may be different, but must not be opposite: the preponderating influence, in point of character, is also with the male, and in point of bulk and hardiness with the female, as it is in animals. Many of the finest varieties of fruits, culinary vegetables, cereal grains, and grasses, have been produced by cross-breeding. When cross-breeding is effected between what are considered different species, the offspring is a mule, or hybrid; is incapable of maturing seeds; and generally, in the course of a few years, degenerates, or reverts to its original parentage. The purple laburnum, which was raised from a seed of the common laburnum, fertilized by Cytisus purpureus, is an example of a true hybrid. The flowers partake of the color of that of both parents; and the plant, for two or three years, produced only flowers of this kind, which were never succeeded by seeds: but in the sixth year, in some plants, and seventh and eighth in others, branches of Cytisus purpureus were produced on some parts of the tree, and branches of the common yellow laburnum on others, the latter bearing seed. (See *Gard. Mag.*, vol. xii. p. 225; and *Arb. Brit.*. p. 590.) It thus appears that a true mule, or hybrid, can with difficulty be propagated, even by portions of the plant, or by what is called extension; since it never can be certain whether the portion taken off for propagation will produce the mule or one of the parents. As it is uncertain what are, and what are not, very distinct species, many of these plants originated by cross-breeding, and considered mules, may not be so; and may, consequently, prove permanent and improved varieties. Some mules, also, such as that between the sweet-william and the common pink, are much less liable to degenerate than others. As some of the most beautiful and useful plants in cultivation are cross-bred varieties, or mules, the subject well deserves the attention of the amateur, who will find it a source of useful amusement and recreation.

Plants agree with animals in the offspring, when it is raised from seed, bearing a general resemblance to the parent; but as, in every family, the children of the same parent differ individually in feature, temper, disposition, &c., so, among seedling plants from the same seed-pod, no two plants will be found exactly alike; and some will occasionally differ considerably from all the rest. Nevertheless, it is an undoubted fact, that all seedling plants not only possess the character of the species from which they have sprung, but even, in by far the greater number of cases, some of the peculiarities of the individual. The seeds of any kind of cultivated apple, for example, will produce plants, the fruit of all of which will more or less resemble that of the parent; though perhaps some one or two among a hundred may be considerably different. Hence, by selecting from beds of seedling plants those which are in any way remarkably different from the rest, new varieties are procured: and, till within the last half century (when artificial cross-breeding began to be practised by gardeners), this was the only way in which an improved variety of any species of plant was procured.

Plants, like animals, are subject to various diseases, as well as to be preyed on by insects, most of which live on plants till they have completed their larva state. Plants are also injured by being crowded by other plants, either of the same or of different species. When these spring up naturally around the cultivated plants, they are called weeds, and the cultivated plant is cleaned from them by weeding; as it is in the case of being crowded by its own species, or by other cultivated plants, by thinning. Plants are also injured by epiphytes, which grow on their outer bark, such as mosses and lichens; and by parasites, which root into their living stems and branches, such as the dodder, mistletoe, &c.

The life of plants, like that of animals, is limited, but varies in regard to duration. Some plants vegetate, flower, ripen seed, and die, in the course of a few months, and these are called annuals; while others, such as the oak and some other trees, are known to live upwards of a thousand years. In both plants and animals, decay commences the moment the life is extinct; and in both they are ultimately resolved, first, into a pulpy or other homogeneous mass, for manures, and ultimately into certain gases, salts, and earths. After death, the decay both of animals and plants may be retarded by the same means; viz. drying, exclusion from the air, or saturating with saline or antiseptic substances.

Hampstead, July, 1838.

THE MILK-SICKNESS OR PUKING-COMPLAINT.

[The subject of the following article requires the aid of the botanist, as well as of the physician, for its investigation and remedy. Even if the particular plant which causes this fatal and wide-spread disease has been really discovered, the knowledge of it will not be extended so far in ten years, by means of such description as is given below, as it would in a month, by being recognized by a botanist, if old, or named and described by one, if it is a new, and, as yet, undescribed species or variety.

There has lately been passing through many (if not most) of the newspapers of the United States, as if a statement of recent facts, an account of the ravages of the "milk-sickness" in a particular neighborhood on the Wabash. It should have been given (if at all,) as an old account. Precisely the same article was republished more than five years ago, in the Farmers' Register. See page 319, Vol. I.]

From the Genesee Farmer.

Mr. Tucker.—I promised, some weeks ago, to give you a brief sketch of the "milk-sickness or puking-complaint," as it is called, that prevails in the west in many places. There never was a disease in any country, where there were so many conflicting opinions respecting the cause. This disease is fixed in the stomach; a fiery burning sensation is felt in the lower region of the stomach, accompanied with a constant desire to puke—the glands are affected; and as the bowels become torpid from the poisonous matter making a lodgment on the stomach and destroying not only the coats of the stomach but affecting all the digestive powers, it is almost next to an impossibility, in an advanced state of the disease, to procure a passage from the bowels. The cattle that have been opened present what is called the "manifold," with its contents as dry as a chip: a part of the substance taken as a nourishment digested, other parts again remaining as when first deposited; the whole region of the stomach having ceased to act! This, in animals, produces what is called the "trembles." The animals may live for weeks in this state, if not entirely overcome; but the attacks, in many instances, are not discernible until there is sufficient action or exercise to produce a circulation of the blood, when the poison diffuses itself throughout the whole system, and soon destroys the animal, and those of the canine or vulture race that prey upon the carcass are destroyed also.

Narrative.—The first persons in the west, that fell victims to this dreadful disease, were Mr. William Tompkins, an emigrant from my father's neighborhood, (Harwood County, Va.,) and a Mr. Bernard Fowler, brother of Maj. John Fowler, who for many years was the only member of congress from Kentucky, when that state was entitled to one representative only. The two persons were neighbors, and lived on Bank Lick Creek, a branch of Licking River, which empties into the Ohio, directly opposite to Cincinnati; they died about the year 1794 or '5. The disease frequently prevailed about the Forks of Licking, as the country was settled—on Raven Creek, another branch—on Eagle creek, a branch of Elkhorn. The next we heard of it was in divers places in the Green River country, so called, the southern part of Kentucky: frequently in divers other places.

As Ohio began to be settled in 1798, '99 and 1800, up to the years 1836, '7 and '8, this disease made its appearance on the Miamis—on the waters of the Scioto, particularly on some of the branches of Paint Creek. Becoming a residenter of Ohio in 1806, I discovered that the Rattlesnake Fork of Paint Creek, and the upper part of Big Darby Creek, were places most affected with it. Some places on Deer Creek, particularly within four or five miles west of London—also places on Mad River, vicinity of Springfield and Urbana. It again was found in different settlements towards the Muskingum; not confining itself to the *flat* regions of the Miamis, Scioto and other places, it had fixed itself in the hilly regions of Kentucky, on Licking and its tributary streams, and in like manner in the flatter region of the Green River country. So it was in Ohio, some portions of the rolling region of country on Hockhocking and of the Muskingum rivers, were afflicted with it also: and it has been subsequently felt in different parts of Indiana and Illinois.

The Cause.—Like others, for many years, my mind was bewildered as to the cause of this dreadful disease. My business leading me to visit every region nearly of the country in Ohio, I felt great sympathy for the afflicted, and an ardent desire to detect the cause. In 1807, I think it was, Col. Robert Rennick then living on the present site of Springfield, Ohio, an emigrant from the South branch of the Potomac, in Virginia, and a great cattle raiser, began to try experiments. His cattle took it, and he effected a cure, as he said, by administering to each steer a bottle of whisky, about a quart. Indeed, *Captain Whisky*, in those days, was almost a *King-cure-all*. But his remedy, in some instances, failed. He then turned out his cattle, let them range over the prairie and timber lands, and as the frost had nipped the green herbage, he followed his cattle to the timber lands, where he found them greedily stripping the foliage and browsing on a stubby and running vine: after eating this, and on returning home, the cattle took the "trembles." We have frequently springs running from high banks into larger streams, collecting from the savannas back, or from beds of vegetable or mineral substances, or the earth, poisonous matter; but this, I was fully satisfied, was not the cause of what is called the puking-complaint, or milk-sickness; for where it prevailed most, there never was purer or more wholesome water issuing from our mother earth. To Col. Robert Rennick's vine, I then began to direct my attention, and full 25 years were spent in making researches and trying experiments, and to go into detail would be too tedious and unnecessary. I found it necessary to lay all theory aside, and to go on *facts*.

Facts.—1. About 1816, a man living in Indiana on the Ohio river, bruised the vine, extracted the juice, gave it to a cat, and it killed it.

2. The vine grows in every region, where the milk-sickness or puking-complaint prevails. Where the vine is not to be found, there is no disease of this nature. This is a stubborn fact!

3. Calling to see a friend living on Darby Creek, in [illegible] whom I had not seen for twenty years, (M[illegible]loud,) in 1832, or '3, he pointed to his wife and remarked:—"She is my third wife, I am her third husband, and in yon graveyard lie 15 of our families taken off by the dreadful disease, the puking-complaint!" "And do you know the cause," said I? "Yes, we have found it out; it is partly a shrub, which, coming in contact with trees, ascends as a vine. I followed my cattle, found them eating of it, and soon taken with the complaint, and some unable to reach home." This awful astounding fact, having before fixed on the vine, led me to make a full disclosure in the papers, which set many doctors, both mineral and steam, by the ears.

4. While the doctors were discussing the subject, and some of them calling my facts in question, a warm friend of mine, John McNeil, Esq., of Frankfort, Ross County, Ohio, a very extensive farmer and grazier, determined on satisfying his own mind, sent out his son to purchase the healthiest steer he could find in the neighborhood, and, to get a good one, paid thirty dollars for it; he

gave the steer the vine, as he informed me; he ate it, and the next morning the steer was found *dead*.

5. Two purchasers of cattle, Messrs. Harrold and Harrod, living in the corners of Clark and Fayette Counties, on the head waters of the Little Miami, I think, had purchased about 120 head: The drove was divided, 60 were placed in a meadow that had been kept clear of shrubbery and vines, and 60 put into an adjoining enclosure, taking in some woodland. The cattle were fed on the same hay and watered from the same well—most of the 60 enclosed in the woodland died. It was winter; snow was on the ground; it was discovered that these cattle had eaten the vine down to the very roots! So this was a *stubborn fact*.

6. A man not far from the same vicinity, by the name of Allen, had a horse that broke out of his enclosure, and ran off into the barrens; he trailed him up, found him browsing on the vine, and had eaten a considerable quantity of it: being vexed at the animal, he caught him and mounted him and rode him home at full speed; this heated the blood of the horse, he took the "trembles," and died!

I could still proceed with statements of facts of like nature; but will in place thereof give—

Vouchers.—The following papers a few minutes ago I laid my hands on, by overhauling some old papers. They have been before published in Ohio, but now taken are from the originals:

I hereby certify, that my father settled upon the waters of Mad River, about the year 1801—that in harvest the cattle took the "trembles,"—that the country was settled some time before the cattle took the "trembles"—[range first eaten on,]—before this "the puking-complaint" was not known among the people—that in cases of cattle having the "trembles" and dying, the manifold of the paunch was dried up—that believing the complaint to be caused by a poison vine, we looked for it, took some of it, and gave it to a calf, and the next morning, (after eating of it,) it took the "trembles." Each of us chewing some, (myself and father,) and it caused the water to run from our stomachs, and we were seriously affected by it; we did not swallow the juice. No one in the country believed it to be the water that caused milk-sickness. The vine described by Mr. Th. S. Hinde is the vine referred to by me.

W. Taylor.

Champaign County, Ohio, Aug. 19th, 1833.

We state, that Thomas Parker, a neighbor of ours, from the information given by him, had a cow that, after eating the vine, died. Our father's cattle also died after eating of it. Mr. Schoonmaker and a part of his family died of the puking-complaint. Mr. S. gave a dog a crock of cream, he ate it and it died. The crows, ravens and buzzards that ate the carcass of the cattle of Mr. Schoonmaker died. Our brother, T. Taylor, lives at the place—the water is pure and wholesome.

Wm. Taylor.
August 19th, 1833. S. Taylor.

I do hereby certify, that I lived in Clark county, Ohio, for sixteen years—that I had been uniformly of opinion that the water drank by the cattle was the cause of the milk-sickness or puking-complaint. Having been told to the contrary, and that it was the eating of the poisonous vine produced it, I did not believe it. I then ate a handful; the next day I was attacked with puking, and sick a month; Dr. Neadham of Springfield, attended on me, and I recovered. I now live on Lewis's Reserve, Logan County. James M'Manna.

August 11, 1833.

Description of the vine.—1. It grows as a shrub, somewhat resembling a hickory or buckeye bush; when not attached to a tree, grows bunchy or bushy at the top. It is also found clinging to fallen timber, old rotten logs, in wet places, near the edge of ponds, creeks and hollows of hills, frequently around stumps along the road, and sometimes in pastures or meadows. It has a singular leaf with one or two notches or saw teeth on each side.

2. As a vine when it attaches itself to a tree, it runs up as a creeper attaching itself to the body of the tree to a considerable height, and bears a berry, with a buff or brown coat, in bunches, and is minutely described as a vine affecting the vineyards of the Asiatics, and styled by the Arabs "*The wolf grape;*" and by Isaiah the "wild grape." I enclose one or two of its leaves for your inspection. Th. S. Hinde.

Mount Carmel, Ill., Sept. 29, 1838.

☞ The poison vine referred to uniformly has three leaves on a stem—the poison ivy *five*, and notched all round. The wild creeper or trumpet flower, a long stem and many leaves.

ADDRESS OF W. S. MORTON, PRESIDENT OF THE AGRICULTURAL SOCIETY OF CUMBERLAND, DELIVERED AT ITS ANNUAL MEETING, ON THE 12TH OCTOBER, 1838.

Communicated for publication in the Farmers' Register, by order of the Society.

Gentlemen—At our last regular meeting, it was determined, that we should, at each annual meeting, invite some gentleman at a distance, to come among us, and address us, on some subject connected with the great cause which has associated us. This resolution, could it be successfully executed, might be productive of much good. Besides the pleasure afforded from hearing such address, much valuable information might be obtained, and a refined and enlarged benevolence, so dignifying to agriculture, might be diffused. I particularly regret, that in this, our first annual meeting, we have failed to enjoy the aid of the highly qualified gentleman selected for this occasion. And I crave your indulgence, while I offer you, in connexion with this disappointment, only my own efforts at the fulfilment of an official duty.

It has been much the fashion of late, to eulogize the present age, for the amazing developements of the talent for discovery, which it has displayed. And, it has been almost equally common, to remark, that, while the other sciences and arts have been wonderfully improved, and new arts and sciences have suddenly sprung into existence, and risen, at once, almost to the summit of perfection, agriculture, as if depressed by its connexion with the earth, has grovelled in the beaten track of ancient usage, without improvement. While I cannot subscribe to the truth of the observation, at least to the full extent, I believe there are reasons, arising out of the nature of man and the constitution of society, which will account for, and excuse any delinquency in this noble pursuit.

In order to secure the utmost exertion of his faculties, man has ever needed the powerful aid of concentrated action, and to be stimulated by the hope of success. While governments have carefully encouraged and rewarded enterprise, in other pursuits—with a few honorable exceptions—they have either embarrassed agriculture, by awkward attempts to afford aid, or positively depressed her, by unjust exactions, or unskilful interferences with her concerns.

From the nature of most other pursuits, their votaries can easily assemble, either for the purpose of regulating prices, appealing to government for aid, consulting for their common good—or they can, with comparative facility, change the place of residence, and adapt their labors or commodities to the state of the market. While the scattered condition of agriculturists, the expensive preparations of internal improvement and other adaptations for their common benefit, the conflicting interests arising from locality, and the sacrifices connected with removal, render most of these objects almost unattainable. The nature of the employment too, requiring such multitudes to be engaged in it, in order to secure food for the race, while it also demands, for great success, such high attainments in science, from its votaries, constitutes another serious obstacle to its improvement.

For the highest success in agriculture, diligent study of its theory, and application to its practice are indispensable. It is true, that many very thriving farmers hold the former in great contempt. But the simplest operation in husbandry has its reason, or, in other words, its *theory*—and whether this is learned from books, derived from the instruction of others, or from personal observation, it is still *theory*, and leads to the practice. The reason why theory in agriculture has fallen into disrepute, is plain: those who make the greatest noise about it, are apt to be speculative, visionary men, who dream of deriving splendid profits, from the wildest schemes, while they have not the industry and perseverance to execute the simplest. The case is the same in all professions. Whenever they get filled with incompetent men, whose high pretensions are betrayed and their ignorance exposed, by their blundering performances, the undiscerning lose confidence in the science they profess, and prefer the boldest empiricism, provided it be not directed by *book-learned theory*. And, perchance, they may fare as well with the one, as with the other. But, sound learning, guiding a conscientious and diligent practice, in agriculture and all the other avocations of man, will always, eventually, secure the approbation and encouragement of strong-minded and judicious men. It is the doom of man to attain high enjoyment and profit, only by ardent and persevering exertion. From this, the agriculturist may not expect exemption. His profession, to attain the dignified station it may claim among the arts of men, should draw for its principles, from the whole round of physical sciences, from the purest morality, and the sublime truths of religion; requiring—for a thorough knowledge of it—perhaps a more arduous course of study and preparation than any other.

For the removal of evils and difficulties of a general nature, the formation of agricultural societies has been resorted to. These, if properly constituted and diligently attended, may effect much good, in the sphere of their action. But, from the nature of the case, they must, for the accomplishment of the grand purposes required by the general interests of agriculture, be entirely impotent. They, moreover, generally die in infancy, for want of nursing. It would be a waste of time, to remark upon the incompetency of our political legislatures, for this purpose. Nothing but the formation of bodies, for the special business, possessing both power and means—something like the Agricultural Board in England, or the Highland Society in Scotland—can be efficient. Such a body of men might be employed, among other things, in ascertaining and recommending suitable routes for roads and other channels of conveyance for the products of agriculture and manures for the improvement of the soil. The time is speedily coming, when the great benefit of lime, gypsum, bone-dust, poudrette, animalized carbon and many other new manures, will be generally admitted and desired. In the present miserable state of internal improvement in Virginia, it is no matter for surprise, that our husbandry should be so defective. From the splendid schemes of extended navigation and rail-ways, now in agitation, we, in this region, are likely to derive but little benefit. We need improvements more limited in their objects and extent. For instance, if a good rail-road, or even a turnpike, so nicely graduated and well constructed, that a good team might draw on it ten thousand pounds, were made from Lynchburg, or some more convenient point on the river below—along one of those fine ridges on the south or the north side of the Appomattox to Farmville, it would afford to some of the valley counties and several counties on this side of the Blue Ridge, a more extensive market for many of their commodities, such as butter, cheese, tallow, wool, honey, domestic linen, &c., while we might be enabled to procure lime for manuring on remunerative terms. Until lime can be procured, at a much lower price than it has heretofore commanded, and our roads and other means of transportation are vastly improved, and until a much greater proportion of our population are engaged in other than agricultural pursuits, there can be no hope of elevating our husbandry to the highest grade. For while these advantages are denied to us, we are almost compelled, as a body, to grow tobacco, for a market crop. This consumes more manure, and more time and attention, than any other. And the benefit of a meliorating rotation of crops, and of almost every other improving method of culture, is placed beyond our reach.

But, the consideration of these general matters, over which we have no control, may be waived, while we attend to those coming more particularly within our province.

Most of us cultivate, on the belt of gray hickory land, extending, in length—with a variable width—from about the mouth of Deep Creek, in Powhatan, to the head of Bush River, in Prince Edward. It is the region, for which the late John Randolph, of Roanoke, said, that God had done more to bless, and man more to destroy, than for any country he had ever seen. Its peculiar characteristics show more strikingly on the Guinea Creeks, than elsewhere, and hence it has usually been called the Guinea vein of land. It is quick, free land, and, after exhaustion, has a wonderful power of resuscitation. This is evinced, even to the eye of the passing stranger, by the quantity of hickory, dog-wood, red-bud and walnut, interspersed among the old-field pines. It is well adapted to the production of corn, tobacco, oats, nearly all the minor crops, and yields wheat much better than would be supposed from the sandy nature of the soil. The spots of red land interspersed through this region, yield wheat finely, as do most of the fields with a red clay substratum, if not too much exhausted.

Feldspar is the most abundant rock, in the bowels of the earth, in this belt of land. The potash, usually found in this rock, may afford to the soil its peculiar fertility when fresh, and its capability to be improved when impoverished, as also its adaptation to the growth of tobacco; for this plant contains much potash in combination with nitric acid. This may also account for the free and improvable nature of much of the other lands between tide-water and the mountains, denied the use of lime. There is, however, generally a little lime in feldspar; but hardly enough to account for the fact stated. Potash, as is well known, enters largely into the formation of vegetable matter, and, being an alkali, may neutralize the acid, in the soil. This theory is apparently contradicted by the fact, that on much of our land most abundantly supplied with feldspar, we find the rankest growth of sorrel, and every indication that the land is greatly poisoned with acidity. It may readily be observed, however, that in such places, the feldspar is harder than usual, and of course, gives off its potash more slowly by decomposition, and, lying very near the surface, whenever the interstices between its strata become surcharged with water, this must ooze into the soil, and produce acidity by its putrefaction. In most cases, deep and well-formed hill-side ditches, and other means of preventing the stagnation of water—which I believe to be the most usual cause of acidity in land—would correct this evil. In many places, there are marshes at heads of bottoms and on hill-sides, produced by strong bars of feldspar, running across the declivity and stopping the current of water. These may be removed, by cutting deep channels through the beds of rock, and forming blind drains for the passage of the water. About these ledges of feldspar, I think, there will generally be found a yellowish-brown clay, resembling that on which the lie of ashes has been spilled, which effervesces freely with acids. We frequently see clay of this appearance, in our roads, near beds of feldspar, but I have never exposed any of it to the action of acids.

I have thought the agency of feldspar in fertilizing our lands, not unworthy your attention, and regret that I have not given it a more satisfactory investigation. As a geological fact it is certainly of some importance; and in agriculture, it will be pleasing, if we can ascertain, that we have, incorporated in our soils, a substitute for lime, though greatly inferior to it; which, though it may not bear transportation to much distance, tends constantly, under proper management, to correct acidity, and of course, according to Mr. Ruffin's ingenious theory, prepares the land to receive benefit from plaster. In all those soils, coming under my observation, where plaster has failed, there is a perfect destitution of feldspar, and I do not now recollect a case of failure, where it exists. But I know my observation, in this matter, has been too limited, to justify my undertaking to lay down rules.

We have also, almost every where in our region, the detritus of hornblende, in the form of bottle-green or black-sand, and, in many places, that of green-stone, in the form of a light pea-green sand. A striking sample of this may be observed in the Guinea road, on the hill-side north-east of Felixville. Both of these are intrinsic evidences of good constitution in the soil, or, at least, warrant the hope of improving by clover and plaster.

Having consumed, perhaps, too much time, with the foregoing remarks, connected with the politics and philosophy of agriculture, I shall have the less space left for remarking on the practice. I have but little cause to regret this, as most of my hearers are much better acquainted with this department of our subject than myself.

The practice of agriculture may be divided into those processes which are intended to preserve and improve the soil, and those intended to protect, to cultivate and to preserve the crops. As we have no time for minute details, and as success in the cultivation of crops depends so much on the improvement of the land, we will attend chiefly to this matter.

In the improvement of land, manuring is the leading process. Indeed, it is the source from which all permanent success in agriculture must flow. Without it, the lands must constantly deteriorate and the crops diminish; while both will improve, if manuring is judiciously and diligently conducted. No man, without a trial, could form an adequate estimate of the quantity of manure which might be made in one year, by a moderate force, applied simply, to what may be termed the *main force of gathering*, from the leaves of the woods, the offal of the crops, ashes, marsh mud, and all other substances convertible into manure. But when to this is added a judicious system of enclosing and rotation of crops, and a skilful apportionment of the quantity of land yielding cattle food, and of the number of cattle, to the wants and means of the farm, the quantity of manure and the increase of fertility—compared with ordinary attainments, in these matters—become amazing.

A manure, pen or stercorary, in a suitable place, into which the children of the family are employed in accumulating weeds and other litter, to be rotted and enriched, by being sprinkled with the dirty slop-waters from the kitchen, the refuse soap-suds, and all other filthy fluids, usually thrown away, would produce a large and rich addition to the manure of the farm. This, however, might generate disease, unless great care be taken to scatter ashes, frequently and liberally over it. These would combine with and neutralize the unwholesome effluvia, and greatly improve the quality of the manure.

Much of the manure, in this country, is lost, by being permitted to lie in heaps during hot weather, burning with fermentation, and steaming off its richest gases. If it be not demanded for some hoe-crop, it would be much better to use it as top-dressing on grass. Thus employed, in dry weather, instead of fermenting as it would in a bulk, it simply loses its moisture, and, in wet weather, its soluble matters soak into the earth, and greatly benefit both the grass and the soil.

If, however, manures are kept in heaps, in hot weather, for the purpose of decomposing their coarser materials, they should be largely mixed, with common earth, sand, clay, or, which I think much better, with the broken coal and burnt earth, from the sites of old coal-kilns. Such admixture causes a more gradual and steady decomposition, and prevents what the Scottish farmers call "*fire-fanging*," viz.: the moulding of the manure, which renders it so light, chaffy and worthless. If I have not been greatly deceived, in a small experiment with the charcoal, it does vastly more than this. It arrests and retains the volatile effluvia of the manure, effectually removing its scent, and forming a chemical compound, in which both ingredients are fitted for the food of vegetables. If any mode of rendering charcoal soluble, could be discovered, it certainly would constitute a fine food for plants, as they all contain so much carbon. It appears to me, that no substance, so easily attainable among us, promises so fairly to become a substitute for lime as charcoal. They have both the same greedy appetence for putridity, taking the smell out of every thing. And while they both long retain the matters with which they are combined, they may equally be disposed to yield them, to the roots of plants, as food. They both, certainly, enter largely into the composition of vegetable matter. As I before observed, my experiment with charcoal impregnated with putrefying animal and vegetable matters was small. I intend to repeat it, with more care, and I would thank any gentleman who will give it a fair trial.

While on the subject of manuring, it may be well to remark, that although we cannot afford to use lime largely, yet it might be profitable to employ it on a small scale. A valued friend, who is a member of this society, informed me, that after washing his seed in brine strong enough to float an egg, that the spelt, cockle, &c., might be skimmed off, he rolled it in lime, and sowed it; sowing a stripe through the middle of the lot, without lime. At harvest, in his own judgment, and that of others, in whom he confided, the wheat whose seed was limed, bore one-third more crop than the other. In this experiment there was one bushel of lime used, to ten of wheat. The experiment is richly worth repeating, if we only aim to get rid of such nuisances as cockle, cheat and spelt—but the whole process is the best that has been discovered, for preventing smut.

Volumes might be written on the improvement of agriculture, gentlemen, and I intended to touch on many other branches of this subject, but having already imposed a tax on your patience, and being unable to furnish you with any matter, with which you are not already familiar, I must conclude.

There is, however, one subject, which I must not neglect. One leading object of our association is, "to increase the ties of good feeling, which already so happily bind us together." If we attain this we shall not have united together in vain. This seems to be, emphatically, the age of discord, and the furies seem to be let loose in the hearts of men. The demon of party has enlisted even the most peaceable, and has made veterans of those who were once child-like. To what extent the fiery fanatical passions of men may rage, is left in awful doubt. But there is much reason to fear that new storms are rising, and will rage, until all that is lovely and desirable among men is destroyed. Be this as it may, the time is coming, when he who can feel that he has honestly endeavored to promote "peace and good-will among men" will possess a jewel of complacency in his heart, worth more than all the diadems of all the conquerors that have lived upon earth. May every member of this society enjoy this blessedness! And may we remember, that while the first and great commandment is, to love God, "the second is like unto it, namely, thou shalt love thy neighbor as thyself."

AN ADDRESS DELIVERED BEFORE THE ROCKBRIDGE AGRICULTURAL SOCIETY, AT ITS ANNUAL FAIR, OCT. 11TH, 1838.

By Geo. D. Armstrong, A. M., Professor of Natural Philosophy and Chemistry, in Washington College, Lexington, Va.

Communicated for publication in the Farmers' Register, by order of the President and Directors of the Society.

Gentlemen of the Agricultural Society,—The subject which I have selected as affording a theme suitable for the present occasion, is—the value of natural science to the farmer. The practical rules of agriculture, and the best methods of cultivating the great staples of our country, would have afforded a more appropriate subject, had I felt myself competent to the task. But with my imperfect acquaintance with those matters, any attempt to communicate information to the members of this society, must have proved worse than useless. The importance of agriculture to the prosperity of our country, and the honor which is due to the independent American farmer, would have afforded a theme in the highest degree grateful to my feelings; but its discussion could not have been of any real value. In such a country and in such a state of society as ours, where the farming part of the community are acknowledged to be "the bone and sinew of our strength," that class upon whom more than upon all others, our national prosperity depends, the poor tribute of my praise, could neither make them more honored in fact, nor to feel themselves so. Precluded as I am from the discussion of either of these subjects which would have been most appropriate to the occasion, I will be pardoned for selecting a theme, which in other circumstances I should have left untouched.

The system of agriculture pursued in this section of country has, within a few years, undergone a change for the better. Whilst a country is new, presenting a deep rich soil, which has never been vexed for the support of man, it makes comparatively little difference in what manner it is tilled. All that is necessary is, to bury the seed in the earth, and in due time to gather home the golden harvest. But if a careless system of agriculture be pursued for a time, the soil becomes gradually exhausted. Instead of gathering an abundant crop almost without labor, the farmer is compelled "to eat his bread in the sweat of his brow." From year to year, whilst the amount of his necessary labor is increased, the return for those labors becomes more and more scanty; until at length a point is reached at which the only alternative left him, is to change his system of cultivation, to emigrate, or to starve. There are portions of our southern country which have nearly reached this point—and the tide of emigration is fast sweeping off their old population to the new countries of the west and south-west, those lands of promise. Accustomed for many years to a certain routine of farming operations, they either would not, or they knew not how to change it for a better. The valley of Virginia, possessing as it does a soil which it is difficult if not impossible entirely to exhaust, has never become impoverished to such an extent;—yet, even from the valley of Virginia, not a few have sought a home in the distant forests of the west. Far be it from me to call in question, either the policy of such a movement, or the patriotism of those who have made it;—doubtless they have found a richer soil; and having carried our free institutions with them, wherever they have gone, they still possess all that which most endears his native state to the bosom of a Virginian. But those who remain behind have a work to perform. By long cultivation the soil has become so much exhausted, that it is necessary for our systems of cultivation to be improved, if we wish still to see "smiling plenty reign in the home of our childhood." Instead of making it, the one absorbing question, how can I get the largest return from my lands this year? our farmers must inquire, how can I get the largest return in a series of years? how can I permanently improve my lands? This I suppose every one is ready to admit; but then the question arises, how is this change for the better to be effected? in what way are our lands to be improved? in what respects ought our systems of cultivation to be changed? It is not difficult to mention some way in which lands may be improved, and some particulars in which our systems of cultivation might be changed for the better;—but to give a correct and full answer to these questions, to state in what manner lands may be permanently improved to the best advantage, and how our systems of cultivation may be changed, so that a given portion of land shall yield the largest return, with most certainty, least labor, least detriment to the soil, is a task which it is impossible to perform at the present day; and we can hope to do it only after long-continued and careful study of the subject.

It is at this point that natural science may be advantageously introduced to assist us in our labors. I know that in time past, while men have acknowledged the importance of applying science to the arts, and in fact to almost every-thing else, they have doubted the value of its application to agriculture. Is this a reasonable doubt? What do we mean by natural science? As I understand it, we mean nothing more nor less, than our knowledge of nature arranged and generalized. Our knowledge on all subjects is, in the first instance, a knowledge of individual facts. After a stock of facts has accumulated, we perceive that many of them are of the same character; these we class together, and include them under a general statement. Again, we observe that some of these facts bear to others the relation of cause to effect, and we arrange them in accordance with this observation. This once accomplished, our knowledge has become science. By this process, the form, and not the nature of our knowledge is changed. Scientific principles are nothing more than human knowledge packed up in a portable form. Founded as they are upon our observation of nature, their application to the affairs of life, is one of the very best methods of testing their truth.

To the arts, and to almost every other business of life, natural science has been applied with the happiest result; and is there any thing which forbids the hope of its being applied to agriculture with equal success? There are departments of physical science, which apply as naturally and as directly to the business of the farmer, as mechanical or chemical philosophy do to the business of the artizan. Such are mineralogy, geology and vegetable physiology. One great object of mineralogy and geology is to enable us to determine the character of soils, to ascertain the elements which enter into their composition, and the proportions in which they severally enter. No one has ever doubted that the difference between a fertile and barren soil, lies in a difference in their composition. There are some combinations of the elements of soil, which seem particularly adapted to the growth of plants, whilst there are others which will scarcely support a scanty vegetation. A piece of land may be rendered barren, either by the absence of some one or more of the elements of good soil, or by the presence of some noxious principle. If the former is the case, it is to the interest of the possessor to supply the deficiency; if the latter, to remove the noxious principle. But how shall he set about this work, unless he know whether it is the absence or the presence of an element which renders his land barren, and also what that element is? Lime and vegetable matter are our two most common manures. To make it a general question, as has sometimes been done, whether lime or vegetable matter is the best manure for land, is very much like making it a general question, whether fire or water is the best agent for doing work. Unless the nature of the work to be done is specified, it is impossible to answer the question. For smelting iron fire is the best, and water is good for nothing; for removing a stain from linen water is the best, and fire is good for nothing. So it is with respect to manuring; it is necessary that we should know the nature of the soil, before we can determine the proper method of improving it. It is (as I have already mentioned) one great object of mineralogy and geology to enable us to ascertain the nature of soils; the former, teaching us to distinguish them by their external characters, the latter by their position.

Let this suffice for mineralogy and geology, I wish to direct your attention mainly to vegetable physiology; a department of natural science, which has hitherto been little valued and little understood; and yet one which applies more directly to agriculture than any other. Under the title of vegetable physiology, is comprehended whatever is known respecting the structure of plants, and the history of vegetable life; embracing our knowledge of the nature of the organs of plants, the offices these organs perform, the manner in which they perform these offices, and the changes which they naturally undergo, or which they may be made to undergo by the art of man. Its object is to lay open the machinery of vegetable life, and to explain the manner in which that machinery operates. In order the more distinctly to illustrate the application of such knowledge to practical agriculture, I will select that which concerns one subject; viz: the circulation of the sap. We all know that plants are nourished by their sap, just as animals are by the blood which circulates through their veins.

If we inquire for the point at which the sap enters a plant, we find it to be the root, but not all parts of the root alike. There is a peculiar class of organs whose office it is to absorb nourishment from the soil; and these are situated along the fibres or smaller subdivisions of the root, of course it is at these points and no others that the sap enters. Let us see if we can make any practical application of this knowledge. If we wish by manuring to assist the growth of a tree, we should place the manure at some distance from the point at which the trunk enters the ground, so that it may lie as nearly as possible over the fibres of the root. If we wish to plant a vine so as to twine around a tree and be supported by it, we should plant it very near to the point at which that tree enters the ground, rather than at the distance of several feet from it; because in this way the two will interfere least with each others growth. If we wish to transplant a tree we should be more careful about the extremities, than about the main divisions of the root. If the root have several branches, it is better to cut off all those branches excepting one and retain that with all its subdivisions perfect, than to cut off the ends of all the branches, as is the common practice.

Again; if we trace the course of the sap during the different seasons of the year, we find that in such trees as the oak, the hickory and the chestnut, it circulates principally in the sapwood during the spring and summer, but during the autumn and winter it retires to the heart-wood and not to the root, as is generally supposed. In order to satisfy ourselves of this, nothing more is necessary than to take a part of the body of a small tree cut in the spring, and of another cut in the winter, and lay them on the fire. The sap will be seen to exude in the first from near the surface; in the second from the heart. Let us see if we can make any practical application of this knowledge. It is generally acknowledged that, that most destructive disease in timber called the dry-rot arises from the presence of the sap. It is generally the heart-wood which we use for timber, whilst the sap-wood is considered of little value. If then the situation of the sap at different seasons is such as I have just mentioned, in order to get our timber free from the sap, we should cut it in the summer and not in the winter. The course thus indicated is, I know, in direct opposition to the common practice of men. As this is a matter of some practical importance, permit me to cite one fact in confirmation of the rule which I have laid down. The fact is mentioned in connexion with many others of a similar character, in a communication from a very intelligent ship-carpenter to one of our scientific periodicals. "In accordance with the common practice of ship-carpenters I was in the habit of cutting my timber in the winter. During the summer of 1820, when engaged in framing a vessel, I found I had no piece which was suitable for a certain place in the frame. It was necessary that the work should go on, and as the only alternative left me, I sent immediately to the woods and had a suitable stick cut; this I framed in with the others. After several years the vessel was sent back to me to be repaired. On examining her side timbers, I found them all more or less affected with the rot, excepting this one, whilst it was perfectly sound."

Again; if we inquire into the nature of the sap, we find that as it enters the vegetable system, it consists mainly of water holding carbonic acid gas in solution. Water has the power of absorbing large quantities of certain gases, whenever it is brought in contact with them. Strange as it may seem to those who have never thought much on the subject, water is porous, and absorbs these gases just as a sponge absorbs water. The great object of manuring, in most instances, is to supply carbonic acid gas to the growing plant. A large portion of this gas is liberated from vegetable matter during its decay; and hence the value of such matter as manure. The gas furnished by the manure, must be absorbed by the water, as it sinks down into the ground. Of course, the water should meet the manure before reaching the roots, and not after it has passed beyond them. This would suggest that the manure could be placed to the best advantage upon the surface, because then the water must pass through it before meeting with any of the roots. But, then, there is a difficulty arising from another source. The valuable material furnished by the manure, is furnished in the form of a gas. If the manure is placed upon the surface, it soon dries, and whilst in that state, as the gas is liberated, no water being present to absorb it, it is soon dissipated in the atmosphere. The two facts taken in connexion, suggest that the manure should be placed as near the surface as is consistent with its being kept in a moist state, and in every instance, above the roots of the plant which it is intended to benefit. Where manure is spread upon the ground in the fall to benefit a winter crop, it should be placed very near to, if not upon the surface; where it is spread in the spring or early part of the summer it should be always covered with earth.

Our knowledge of the nature of sap, enables us to explain the manner in which clover improves land. Had we no experience on the subject, it would seem, to say the least, improbable that any crop could improve land. We would naturally suppose that plants were nourished by the ground itself—that they fed upon the soil. If such be the case, when a crop is ploughed under and decays, it can give nothing but what it has first taken; and how then can it improve land? Yet we find that growing clover upon land, and then ploughing it under and suffering it to decay, is one of the very best methods of improving land. Bearing in mind the nature of the food of plants, this admits of a simple explanation. We will suppose that clover is sown upon a perfectly barren spot. The atmosphere which is above this spot, contains a portion of carbonic acid gas, for all atmospheric air contains a greater or less portion of it. A rain comes; as the rain falls, it absorbs a portion of this gas, and in this condition enters the ground. No sooner does it come in contact, with the seed in the first instance and with the root afterwards, than it is absorbed and its materials used for increasing the size of the vegetable structure. When the portion of air above the spot, has in this way been exhausted of carbonic acid, a supply is obtained from the neighboring portions, in consequence of that strong tendency which gases manifest, to intermix and diffuse themselves throughout each other. This process is repeated again and again, and thus the clover increases in size. Perhaps some one may ask, from whence is this gas obtained in the first place? From many sources, but principally from decaying vegetables, such as are found in the woods and along the fence sides. The quantity of the several elements which enter into the composition of our globe, is fixed; it is impossible for man either to increase or diminish this quantity, and it is equally impossible for him to convert one of these elements into another. All he can do is to make an economical use of that which already exists, to gather up those portions which subserve no valuable ends, and apply them to use. This is what the farmer does in sowing his land with clover. He impresses the very wind into his service, for every wind that sweeps over a field of clover, laden as that wind is with the materials of vegetable structures, is made to contribute to its growth. After a large portion of vegetable matter has, in this way, been collected upon the once barren spot, it is ploughed under and secured for future use.

Again; in absorbing nourishment from the earth, the roots of a plant do not seem to exercise any choice; but drink up every thing, presented to them in a sufficiently fluid state. This we learn from actual experiment. Almost any substance which is soluble in water, may be made to enter vegetable systems. After a heterogeneous mass is thus taken up by a plant, such portions as are suited to its nourishment are retained, whilst such as are not suited, are returned to the roots, and by them again deposited in the soil. From observation, we learn that the matter thus rejected, is thrown back in such a state as to be not only unsuitable to the nourishment of the plant (rejecting it) but positively deleterious. It has also been ascertained, that the substances rejected by different plants differ from each other; and this to such an extent that the matter rejected by one plant, is well adapted to the nourishment of another. With a knowledge of these facts, we can assign the reason, why it is not a good plan to sow the same crop upon the same pieces of land for several years in succession. It will not do to say (as is often done) that a second crop of wheat will not grow as well upon the same spot, as the first, because that spot has been so much exhausted by the first. This is, it is true, one reason; but if it be the only reason, or even the principal reason, why is it that a crop of corn succeeds so well? The failure in the second crop of wheat, arises not so much from the exhaustion of the soil, as from that soil's containing a portion of matter positively deleterious to the growth of wheat, and which was deposited by the first crop. At the same time this matter is not injurious to the growth of corn, and hence the crop of corn is almost as good as it would have been, had wheat never been sown upon the land. If we could ascertain the precise character of the matter which is retained, and of that which is rejected, by each of the several crops commonly cultivated, it would be an easy matter to determine the best order in which crops can succeed each other. Perhaps too, if this subject was better understood, we should find that the way in which some manures benefit crops, is not by supplying nutritious matter to them, but by removing this deleterious matter from their roots. If this matter possess the character of an acid, as it is more than probable it does in some cases, lime would act in this way. Being a salefiable base, it would unite with the acid and neutralize its properties.

I might go on and multiply instances such as these, did the occasion call for it: but as my object is, not to give a lecture on vegetable physiology; but by illustrating its application to agriculture, to show its importance to the farmer, these will suffice. Perhaps some one may ask, if scientific principles are nothing more than facts, araged and generalized, why is it, that knowledge in this form, is more valuable, than in the form of unconnected observations; the form in which this knowledge is at first obtained?

There are several reasons. Knowledge in the form of science is more easily retained, and is more perfectly at the command of the possessor, than it can possibly be, in the form of unconnected observations. I doubt not that the experience of every one here will confirm the statement, that it is easier to remember fifty effects, when we can trace them to one common cause, than it is to remember five, when we can trace them to no cause. A knowledge of the cause of any number of effects, serves as a band, by which they are bound in one common bundle, and thus secured from being scattered and lost. It is one of the characteristics of science, that the relation between cause and effect is distinctly traced out.

Another reason why it is desirable to have our knowledge in the form of science is, that in this form it will serve to direct us in our course of experiment and observation. Such is the constitution of nature, so intimately are the various parts of creation interwoven, that a cause generally gives rise to several effects. When we have traced an observed effect back to its cause, we can generally infer other effects, which will spring from the same cause; and these often of a character entirely different from the one first observed. To illustrate my meaning by an instance. In attempting to sink a pump to an uncommon depth, it was found that the water could not be raised by it, to a height greater than 32 feet. The cause of the rise of the water was ascertained to be the weight of the atmosphere. The reason why the water would not rise to a height greater than 32 feet, was that the weight of a column of our atmosphere was only equal to that of a column of water of the same diameter, and 32 feet high. It was at once inferred, that as the weight of the atmosphere was fixed, it must sustain columns of different liquids at heights, inversely proportioned to their specific gravities. And again; that as we rose from the level of the sea, leaving as we must, a part of this atmosphere behind us, the height at which a column of any liquid would be sustained, must diminish in proportion to our rise. Thus by tracing the refusal of a pump to act in certain circumstances, to its cause; we ascertain, in the first place, a method of determining the specific gravity of liquids; and in the second place, a method of determining the height of mountains. The effects by which we determine these things, spring from the same cause as the refusal of a pump to act, and yet they are of such a character that we never should have dreamed that there was any connexion between them, had we not traced them to their common cause; and more than this, we should probably have remained long in ignorance of the two last mentioned effects, had we not traced the first to its cause. Thus it is, that throwing knowledge into the form of science, is like putting it out at compound interest.

Another reason why it is important to have our knowledge in the form of science, is that in this form it will greatly assist us in observing facts, and collecting information. When the attention has been directed to any particular subject, facts connected with that subject are observed and remembered, which, in other circumstances, although they might have passed before the eye, would have made no impression on the mind. Let a farmer and an architect travel together, through the same country, you will find that although they must have seen the same things, yet they have brought home with them entirely different kinds of information. The farmer can give you an account of the soil, the condition of the crops, the methods of cultivation, &c.; whilst he can tell you little or nothing of the structure of the buildings which he has passed. The architect, on the other hand, can give you a minute description of every principal building on the way; whilst he can tell you little or nothing respecting the crops. This difference arises entirely from the fact, that these two men have had their attention previously directed to different subjects. By throwing our knowledge into the form of scientific principles, we get a number of subjects worthy of attention, distinctly out before the mind, and each of them will be a nucleus around which knowledge will naturally collect.

Such are some of the arguments, which urge a study of natural science upon the farmer. The want of success, which has in many instances attended the efforts to apply science to agriculture, may be brought forward as an objection, by some. To such I would answer, this want of success is to be attributed, in part to the present imperfection of those sciences which most naturally apply to agriculture; and in part also, to the visionary character of many of those who have hitherto made the attempt. If you will consult the history of the application of science to those of the arts to which it has been most successfully applied, you will find that this has been a misfortune which has happened to them all, in their infancy. Visionary men being the lightest part of society, seem always to rise to the top; and rising science, like the rising sun, is forced to shed its first rays upon those barren spots, where it is impossible that any thing should grow. Let it rise higher, and pour its flood of light upon the rich valleys below, and if it cause not these to spring with life and verdure, then may you fairly call its claim in question. If the attempt has failed hitherto, in consequence of having been made by visionary men, the greater is the necessity that sober, substantial, practical men should now take the matter in hand.

Much has already been done in Virginia for the advancement of the interests of agriculture. A geological survey of the state is now in progress. An able periodical, devoted exclusively to diffusing information respecting the best methods of cultivating and improving land, has been established, and thus far well sustained. And last, though not least, societies such as that whose anniversary we to-day celebrate, have been established in many parts of the state. Thus far it is well. There is yet another, and, as it appears to me, an important step to be taken. The nature of that step and my reasons for believing it important, I have presented before you. "I have spoken as unto wise men, judge ye what I say."

Every inducement is held out to the farmer of the valley to improve his land and his system of cultivation. Who that looks upon the inexhaustible water-power of our state, and at her vast mineral resources; the iron and the coal, which the hand of a bounteous Creator has so lavishly bestowed upon her, can doubt, that she is yet to become one of the principal manufacturing states of the union. Thus will she possess within herself a market for all that her farmers can produce by the most skillful cultivation. The James River improvement will soon open a grand highway, from the valley to the very centre of this market. Our climate is well adapted to the growth of every species of grain; our soil is already good, and susceptible of the highest degree of improvement. What then is there to forbid the hope, that the valley of Virginia may yet rival in fertility the fairest portions of the west? Let our farmers but improve the advantages which they have; let them engage in earnest in this work, and this hope must soon become a reality.

The traveller as he rests for a moment on the top of yonder mountains, will cast his eye over a broad land of golden harvest. As he descends and mingles amongst us he will receive the hospitality of an intelligent, a blest, a happy people. The inhabitant of the valley has already much to rejoice in. He trembles not before the chill wind of the north, neither is he striken down under the oppressive heat of the south; surrounded by a scenery so grand and beautiful, that no part of the country can boast a superior; possessed of a mount-girt home, such as has always been the strong hold of the freeman, let him but add to these, that fertility which he can bestow upon the soil, and with an honest pride may he exclaim, my own, my native valley, is the fairest spot on which the sun shines.

From the Genesee Farmer.

SPANISH CHEESE PUMPKIN.

Mr. Tucker—If you think the following notice of an agricultural production worthy of a place in your paper, you are at liberty to insert it.

I have the present season, from the planting of one pumpkin seed, raised twenty pumpkins, weighing in the aggregate, 671 pounds.

The six largest weighed as follows: 71, 71, 70, $62\frac{1}{2}$, 60, $57\frac{1}{2}$, making 392 lbs.; 14 others weighed 279 lbs., making 671 lbs. Whole length of the the vines, 989 feet.

They are of the kind called the Spanish cheese pumpkin, yet, notwithstanding the name, they are evidently a winter squash, not as rich in quality as some of the smaller kinds, but much richer than the common field pumpkin, and may, with proper care, be kept through the winter.

ISAAC CURTIS.

Brighton, Oct. 10, 1838.

PREMIUMS AWARDED BY THE AGRICULTURAL SOCIETY OF ALBEMARLE, 2D AND 3D NOVEMBER, 1838.

Horses.

To Col. William Woods, for his stallion Clarence, the first premium of - $15
To George W. Craven, do. do. Gen. Warren, the 2d do. - - - - 10
To John Rodes, do. brood mare Rosina, the 1st do. - - - - - 10
To Stephen Price, do. do. 2d do. - - 8
To William Garth, for his 3 year old gray colt, by Graybeard, the first premium, - 6
Do. do. 3 year old sorrel colt, by O'Kelly, the 2d do. - - - - - - 5
To Col. William Woods, for his 3 year old black filly, by Murat, 1st do. - - 5
To Captain Thomas Davis, do. do. sorrel do. by Goliah, 2d do. - - - - 4
To William Tompkins, for his 2 year old gray filly, by Oscar, the 1st do. - 5
To Reuben Lewis, for his 2 year old filly by Murat, 2d do. - - - - - 4
To William Gilmer, for his yearling filly by Terror, 1st do. - - - - - 5
To Col. William Woods, for his bay filly by Murat, 2d do. - - - - - 4

Cattle.

No bull over 4 years old exhibited worthy a premium.

To Jesse Garth, for his full blooded Durham bull, Major Downing, under 4 years old, the first premium of - - - $5
To Gen. J. H. Cocke, for his full-blooded Durham bull, Young Patrician, under 4 years old, 2d do. - - - - 4
To Gen. J. H. Cocke, for his full-blooded Durham cow, Cindarella, 1st do. - 6
To Jesse Garth, for his full-blooded Durham cow, Roanoke, 2d do - - - - 4
To Gen. J. H. Cocke, for his full-blooded Durham heifer, Dowager, 1st do. - 5
To Nelson Barksdale, for his spotted heifer, by his full-blooded Devonshire bull, 2d do. - - - - - - 4

Sheep.

To Reuben Maury, for the best ram, - $5
To William Garth, 2d do. - - - 4
To R. Maury, for best pen of ewes - 5
To William Garth, for 2d do. - - 4

Domestic Manufactures.

Woollen, and Cotton and Woollen Goods.

To Mrs. John Rodes, for the best piece of flannel, all wool, - - - $5
To Mrs. John H. Craven, for the best piece of flannel, wool and cotton, - - 3
To Mrs. William Woods, for the 2d do. do. 2
To Mrs. Jesse Garth, for the best piece of carpeting, - - - - - - 8
To Mrs. Peter McGee, for the best hearth-rug, - - - - - - 4
To do. do. 2d do. - 3
To Mrs. John H. Craven, for the best piece negro winter clothing - - - 6
To Mrs. Sarah Woods, for the 2d do. - 5
To Mrs. George M. Woods, for the 3d do. - 4
To Mrs. Jesse Garth, for the best wool and cotton counterpane, - - - 4
To Mrs. Jesse Garth, for 2d do. do. - 3
To Mrs. Robert Gentry, for 3d do. do. - 2
To Mrs. William Woods, for the best pair woollen socks, - - - - - 2
To do. do. 2d do. do. 1
To Col. William Woods, for the best suit home-made clothes, - - - 10
To Dr. Jno. R. Woods, 2d do. do. - 8
To Richard D. Sims, 3d do. do. - - 6

Cotton and Linen Goods.

To Mrs. R. D. Sims, for the best piece of negro shirting, - - - $5
To Mrs. Dr. Brown, do. 2d do. - - 4
To Mrs. R. D. Sims, for the best piece shirting or sheeting, - - - 5
To Mrs. Col. Woods, do. 2d do - - 4
To Mrs. Peter McGee, for the best cotton counterpane, - - - - 3
To Mrs. M. Johnson, do. 2d do. - - 2
To Mrs. Dr. Brown, for the best piece flax and cotton diaper, - - - 5
To Mrs. Col. Woods, do. 2d do. - - 4

Butter and Wines.

To Mrs. Frank Nelson, for the best specimen of butter, - - - - - $4
To Mrs. R. D. Sims, 2d do. - - 3
To Mrs. G. W. Kinsolving, 3d do. - 2

Only one specimen of domestic wine exhibited, which, although good of its kind, (currant,) was not deemed worthy of a premium.

GLANDERS COMMUNICATED FROM A HORSE TO A MAN.

On Saturday week, an adjourned inquest was held at the Champion, Princes-street, Lisson Grove, on the body of John M'Lellan, whose death occurred under the following circumstances. The jury first proceeded to view the body of the unfortunate man, which presented a spectacle too horrible to describe, the face being entirely eaten away, and the whole body being one mass of sores from top to toe. From the depositions, it appeared that the deceased was the driver of a cab and horse, the property of Mr. W. Johnson, a cab owner, at the west end of the town. On the evening of Friday week, deceased came home, and complained of having a cold. He took some gruel, and went to bed. On the following day, large lumps or swellings began to make their appearance under the jaw and on the nose, which, as well as the eyes, emitted a great deal of running. The eyes gradually became worse, and full of holes, and the nose and jaw broke out into dreadful sores. Medical aid was called in, but the gentleman who attended was unable to tell the nature of the disease. On Wednesday week deceased was conveyed in a cab to Sir Astley Cooper, who examined him, and pronounced it to be the glanders, caught from a horse. The deceased's medical attendant subsequently fell in with his opinion; but all remedies were found of no avail. The unfortunate man gradually became worse, and entirely insensible. In the space of two days his nose fell from his face, and his eyes became like a colander, both emitting a thick mucous running. He, however, about a quarter of an hour before his death, which took place on Thursday evening, recovered his senses, and stated that he had got his death by wiping the horse which was glandered with his pocket handkerchief, and then incautiously using the same to wipe his own nose. He expired in the most excrutiating agony. The jury returned a verdict "That the deceased died from glanders accidentally caught from a horse, of which he was the driver."—*London Paper.*

SINKING OF DRAINED SWAMP LAND.

[The following is an interesting account of the *sinking*, as it is called, but which is more properly the *rotting away* of vegetable soil, after its being dried and cultivated. The intelligent writer did not seem to be fully aware of the cause and manner of the disappearance of his soil. Before draining, for cultivation, any marsh or swamp, the undertaker should examine carefully the quality and chemical composition of the soil, so as to know whether it is of vegetable, putrescent, and therefore perishable matter, or sufficiently earthy to be permanent. Especially should this important point be settled before undertaking such great and expensive, and yet we hope most valuable and profitable public works, as the drainage of the immense body of swamp lands belonging to the Commonwealth of North Carolina, as ordered by the legislature.—ED. FARM. REG.

From the American Farmer.

Poplar Grove, St. Paul's,
South Carolina, May 20, 1823.

To the Editor—A correspondent in one of your late numbers, ask for information through the medium of your paper, relative to the reclamation of marsh land, which is covered with a heavy growth of trees—such as ash, maple and gum. He says, that an impression exists in his neighborhood, where large bodies of that land are to be met with, that woodland marsh, when reclaimed, will sink more than that which is free from wood. If any conclusive experiment has been made of this kind of marsh, I should be pleased to know the result; when convenient, if you will make the inquiries, to obtain information on the subject, I shall be obliged to you. As I have derived much instruction, and received a great deal of pleasure from the pesusal of your interesting paper, I will lay before you the result of an experiment, which I think will be conclusive to the mind of your correspondent, that I have made upon two hundred acres of marsh land, which was once as heavily wooded with cypress trees, as perhaps any swamp in Carolina; and of which I gave you some little account in Vol. 2, No. 44.

My plantation is so situated, that at the lower extremity, where I formerly embanked about two hundred acres, the tide-water is generally brackish, and oftentimes salt. It is so embodied with the old rice fields, that in order to supply it with the quantity of water necessary for the cultivation of rice, I dug a canal of twenty feet wide, and four miles long, entering the creek where the tide ceases to flow, and where from the drainings of a swamp many miles in extent, it is generally fresh; from whence at the flood tide my rice fields are supplied, and assisted in a drought by a long reservoir of water. The beautiful level appearance all alluvial soils exhibit to the eye, connected with its natural richness, induced me, about the years 1793 and 1794, to commence the undertaking, and which I have never had reason to repent. After many laborious and ineffectual attempts to get rid of the rushes, and turn up the land with ploughs and hoes, I became almost disheartened, being at a loss in what manner to proceed to effect pulverization, without which, the scheme must prove abortive. It occurred to me, that notwithstanding my ditches were dug three feet deep, there yet remained too much sobbiness in the land, to allow the successful operation of the plough. Satisfied of that fact, I dug up my river trunks, and replaced them at six inches above low water mark, sunk the ditches to the depth of five feet, and struck quarter acre drains about three feet deep. The effect was visible in the course of a few months; the rushes being deprived of that nourishment, they had been accustomed to receive from the sobby state of the land, died away. A fire was then applied on a windy day, which consumed them. The plough and hoes were again resumed, and I had the satisfaction of seeing the work progress. The land having now assumed a light husky appearance, very much resembling the peat morasses in Scotland, was thrown into large potato, or corn beds. In a short time a fire was again applied, which burnt them smooth to the ground, leaving ashes of a red color. It was repeated during the course of the winter, and in the spring, partial crops of corn, oats, barley and rye were planted upon a small scale, all of which failed. Perseverance, however, in tillage, and attention to the depth of my ditches, at length overcame all these discouraging results; the land, in due time, produced rice, cotton, corn, barley, rye and oats, all of which I have had since growing as a part of my crop, particularly barley, which was harvested about the 15th of May, and the land immediately planted in rice, making it produce two crops in one season.

The land, by constant cultivation, has sunk so much, that it is almost incredible to suppose the probability of a plough, drawn by oxen, could have gone over many parts of it. Large cypress stumps and roots have since risen up, and now show themselves 18 or 20 inches above the surface of the land, with the visible marks of the axe. The main bodies of the trees have been removed, many of them six feet in diameter; here and there a large limb is found, which has been squared by my carpenters, and carried home, for the purposes of building—and here, Mr. Editor, arises a question for those who are fond of diving into these matters, who were the persons that applied the axe, and to what market were the trees carried? From the above statement, I think your correspondent will view it in the light of a conclusive experiment, that heavy wooded marsh land sinks more than any other kind of land without wood.

Before I conclude, I will adduce one more instance, still more conclusive, of the excessive sinking of this kind of land. In digging the canal, above mentioned, a piece of the land in question, consisting of about 20 acres, was enclosed by the embankment, wooded with the identical kind mentioned by your correspondent—ash, maple, gum—besides a few very large loblolly pine trees, a quantity of palmetto and cedar bushes, and the greatest part covered with rushes. This land, through which a creek runs, was so completely raised, that nothing but a very high spring tide, aided by an easterly wind, could at all affect, (the tide with me rises six feet)—knowing it to be of the very first quality, I ordered it to be cleaned. Since which, it has produced abundantly of every kind of grain, planted on our low country. It now ranks among my first rate fields, and often produces fifty and sixty bushels of rough rice to the acre. I remain, very respectfully,

CHAS. E. ROWAND.

From the Edinburgh Farmers' Magazine.

REVIEW OF THE COMPARATIVE STATEMENT OF THE EXPENSE OF OXEN AND HORSES FOR FARM-LABOR, GIVEN IN THE NORTHUMBERLAND SURVEY.

As the authors of the Northumberland Survey, reviewed in your fourth number, appear to have very much undervalued the expense of keep, both of oxen and horses, I have sent you an attempt at a new estimate of both, on what seem to me truer data.

Expense of an Ox for one year.

Summering on grass, being the customary payment for a cow .		£ 3 10 0
¼ of an acre of tares during summer, at £5 . . .		1 5 0
Wintering on straw .	£ 1 10 0	
½ an acre of good turnips, at £5 . . .	2 10 0	
	4 0 0	
If on hay, 200 days at 8d.	6 13 4	
Half of this, as the average expense . .	10 13 4 is	5 6 8
Interest, harness, shoeing, as per Survey . . .		1 5 0
	Total	11 6 8
Deduct supposed increased value of the ox . . .		1 6 8
Gives the annual expense of one work ox . .		£ 10 0 0
Hence, the 1st year, with 8 oxen, will cost .	£80 0 0	
The 2d and 3d years, 6	120 0 0	
Expense of three years	£ 200 0 0	
Average for one year . .		£ 66 13 4
To which must be added, the expense of a driver, which I cannot estimate, including wages and victuals, below		14 6 8
Gives the total annual charge of each ox plough . . .		£ 81 0 0

Expense of a horse for one year.

Summering on grass, 165 days, at 6d.	£ 4 2 6
Vetches or tares, as for the ox .	1 5 0
Straw for half the winter, at the same rate with the ox . .	0 15 0
Hay half the winter, or 100 days, at 8d.	3 6 8
Oats, 70 bushels, at 2s. 3d. .	7 17 6
Harness, shoeing, and annuity, as per Survey	3 5 0
Annual expense of one horse	£ 20 1 8

Hence, the annual expense of a two-horse plough will be £41 3s. 4d., leaving a balance in favor of horses for farm labor, and against the use of oxen, of £39 16s. 8d. for each plough. The ploughman is not charged in either, being the same in both.

In the strongest soil, the improved *swing-plough* can never require more than three horses, and that only for once ploughing, in particular seasons and situations. Suppose three required for half the year, and with a driver, this would add £17 7s. 2d. to the expense of each horse plough in such stiff soils, still leaving a balance of £22 7s. 6d. against each ox team.

Extending this comparison, with the authors of the Survey, who suppose 5000 ploughs in Northumberland, and, allowing Great Britain and Ireland to contain forty times the extent of tillage land in Northumberland, the two-horse ploughs give a difference of nearly six millions sterling annually. Supposing half the ploughs to have three horses, the difference would be nearly five millions. In such years of scarcity, the difference would be more than double.

It must, however, be observed, that the above comparison is made with the improved swing-plough, and will by no means hold good with the extravagant horse-teams so prevalent in the South, which are more expensive even than ox-teams.

It would go a great way towards lessening the danger of future scarcities, to devise a means of introducing the swing plough universally into practice. Perhaps a tax, increasing annually, upon all ploughs drawn by more than two, or at most three horses, would answer the purpose. A similar tax on boats constructed of hewn timber, very speedily introduced the saw into Russia.

The *second* calculation respecting the value of produce, by using ox-labor, comes much nearer mine, than the direct estimate of expense. Had the authors allowed nearer the average price, the difference would not have been very material.

They calculate directly the loss on each ox-team	£ 8 3 0
Estimate of lots of produce by each is	17 13 0
My calculation with two-horse ploughs	39 16 8
Ditto with three horses . .	22 7 6

The average of the whole is .	£24	10 $7\frac{1}{2}$
And, leaving out the first, as greatly too low, the average will be almost	30	0 0

Upon the whole, the loss to the farmer, in the first instance, cannot be under £25 annually for each ox-plough team.* And it may be worthy of remark, that the whole of this loss must ultimately fall upon the landlord and the community.

R. R. R. R.

From the American Farmer.

FISH AS MANURE. STATEMENT FOUNDED ON EXPERIMENT.

Sir—I promised you, when I had the pleasure of seeing you here last year, that I would give you the result of an experiment made by using herrings as a manure; and since I have fully tested the experiment, I now give you the result, with all its minutiæ. In May, 1822, I purchased 32,000 herrings, and placed them in drills four feet apart, on 4023 square yards of ground, which is 817 yards less than an acre—they were placed quite thick in the drills—and then covered with a plough, by throwing two furrows together. On the 24th May, I finished planting the ground in corn, by dropping the same on each side of the drill at about three feet apart; but found when the corn grew about three feet high, it was much too thick, and was compelled to plough out every other row. The corn was once ploughed with a small corn plough, and twice with the cultivator, which was all the cultivation I gave it—the corn yielded, when gathered, a fraction more than 30 bushels; and although last year the corn in this neighborhood suffered much from the long drought, it had upon this corn no apparent injurious effect. While the leaves of other corn in its immediate neighborhood were dead and dried up above the ear, this was perfectly fresh; and the dry weather appeared not at all to affect its verdure.

On the 10th of October, I again ploughed the ground, and on the same day, sowed the same with two bushels of wheat. In the spring, the wheat grew so luxuriantly, I found it necessary to cut an acre with a scythe. It again very soon covered the ground. The weather preceding harvest was very favorable to this wheat, being uncommonly dry: had it been wet, I believe not one bushel would have been gathered. Dry as the weather was, it was cut with much difficulty, it had fallen to the ground so much. It yielded, when carefully taken from the straw, twenty-nine bushels. You saw the ground yourself, and know how very poor it was—and I am persuaded, had the fish been placed with some regularity on the surface of the ground, in the place of drills at so great a distance apart, by which the ground would have been regularly manured, it would have produced several more bushels of wheat than it did. As it is, it yielded at the rate of $34\frac{3}{4}$ bushels to the acre. I now give you the cost and profit:

32,000 herrings, at 31 cents -	$9 92	
Hauling five loads of herrings at $1 25 - - -	6 25	
Ploughing in ditto - -	1 00	
Expense of planting and cultivating corn - - -	3 00	
		$20 17
Cr.		
By thirty bushels corn at 75 cents, which was the price last fall - -		22 50
Clear profit on the first crop - -		2 33
I say nothing of the fodder, leaving that to pay the expense of getting in corn.		
29 bushels of wheat at $1 25 - -		36 25
		$38 58
Expenses.		
Two bushels of wheat at $1 25 -	$2 50	
Cultivation - - -	2 50	
		$5 00
Clear profit, leaving the land rich - -		$33 58

I would here remark, that although I used 32,000 herrings, 20,000 to the acre is quite sufficient, and will make a more certain crop than a greater quantity. I have used this spring, cat-fish and perch for my potatoes, and find them as good again as the best stable manure; and you will find at Messrs. Bradford & Cooch's, in a few days, a barrel of potatoes made from the fish—also a few at the top of the barrel in paper, the seed of which you gave me last fall—they were, I think, sent you from the north—they grew well with me, and are the finest potatoes for the table I ever saw.

Yours, respectfully,

BENJAMIN F. MACKALL.

Wilna Mills, Cecil Co., Oct. 12, 1823.

From the American Farmer.

SHEEP HUSBANDRY OF R. R. MEADE, DEC'D.

Read at the last meeting of the Agricultural Society of the Valley, (1824) and by order of said Society communicated for publication in the American Farmer.

Gentlemen—If an apology were necessary in making a communication to farmers on the subject of their profession and prosperity, I might find it in the queries propounded by our secretary, and his invitation to a free exchange of information on agricultural topics; also in a sincere desire I profess for the improvement of our husbandry through agricultural associations. Under similar impressions I had been in the habit of sending to the American Farmer the result of my efforts to improve the breed of sheep, with a hope of exciting a more special attention to that part of our occupation, but the suggestion of a member that any remarks made on the subject might reach those useful pages through the medium of our society, determined me in the propriety of respectfully placing at your discretion the report of my last shearing, with a few observations thereon—perhaps in the infancy of our institution, and in the absence of learned or scientific communications, a plain practical relation of facts may be interesting, and enable you to turn them to some advantage. The subject in my humble opinion has not receiv-

---

* We humbly recommend the above observations, together with the comparative statements between horses and oxen, for the purpose of the draught, presented in the Northumberland Survey, to the consideration of those members of the Legislature, who supported the bill for taxing farm horses, solely because it would operate as a premium in favor of oxen.

ed its share of discussion in the agricultural journals of our country, especially as it bears a double relation to our wants and our comforts. It is from the same animal that we obtain the choicest and most wholesome supply of food for our tables, and the material for a great variety of clothing suited to a vast extent of climate. The improvement and increase of our wool and mutton must then be an object of great concern to both rich and poor; and if by a change in management we can obtain more wool and meat from one-half, or two-thirds of the animals kept, our soil must consequently improve under an additional covering of grass, and we be immediately benefited in the increased quantity of tallow, flesh, and wool. There is a beguiling propensity with most of us to crowd our lands with stock, preferring, as it would seem, numbers to quality, and forgetting the difficulties attending a dry climate and long winter. When in the habit of keeping double the number of my present stock of sheep on the same ground, I was compelled at particular seasons to go to extraordinary expense in their feeding to keep them in a thriving condition. Notwithstanding, the average weight of their fleeces fell from eight to between four and five pounds. Experience then teaches me to keep no more sheep than I can feed well with economy, and have those separated in warm weather, never increasing their expense, risk, or trouble, by having lambs sooner than the first or middle of March, when they may have green food. A rye lot proportioned to the number of breeding ewes need be the only additional expense in keeping, to common pasture and good wheat straw when the snow is on the ground. A slight portion of Indian meal (too little to be called food) should be given them once or twice a week throughout the year, mixed in their salt. With the aid of improvements through crosses and selection, I will venture to say our flocks will double their produce in a short time. With regard to the expense of an individual flock, I may almost say that mine cost me nothing last winter. The weather, to be sure, was uncommonly favorable. A rye lot of nine acres divided, was their chief food, which was grazed until the 10th of April, and left pretty bare. I have hired the thrashing of the rye, in order to ascertain the quantity in time for your information. Two hundred and twenty-three bushels have been measured up, and I have no doubt there was two or three bushels left on the ground per acre, not having horse-raked it, as was the rest of my stubble (nearly twenty-five bushels per acre.) I had like to have forgotten a considerable part of the production of this ground. Turnip seed was sowed the last of August, with the rye, at the rate of two pints per acre, and harrowed in. Very late in the fall the largest were carried off, and the sheep had ample provision in the balance, preferring turnips to rye. I had hoped at this time to have been enabled to make a comparison between the productiveness of the long wool, and the merino; and to have ascertained how much good wool they sheared to the pound of flesh, but the circumstance of my long woolled sheep being in their prime, and the merinoes on their decline (not having bred from them for four or five years but by the long wool cross) would make an unequal comparison, and I should be sorry to venture an opinion lessening the value of the one, or increasing the value of the other, without a confident experience of both. Take them as they are, a few of the best selected from each, prove in favor of the long wool, nearly two to one, with regard to the fleece; but we must give the merino the credit of imparting a large share of this value to the long wool, for it appears, as far as my observation has extended, that the first long wool cross on the merino has the heaviest as well as the finest fleece. If this be the fact, my determination to select the finest, closest woolled males to breed from, will have the desired effect of uniting as nearly as possible the quality and quantity; the same practice will, of course, apply to other breeders of a similar stock.

Several of the first shear long wool, produced at the rate of one pound to every ten and eleven pounds weight on the hoof. The merino, Arlington long wool, and Tunis sheep are the most noted and valuable breeds immediately amongst us, and according to the situation and views of the breeder, deserve the greatest attention, either to perfect them as a distinct stock, or by judicious intermixtures to produce such valuable varieties as their nature, controlled by our skill, is possibly susceptible of.

June 3d. Sheared 49 sheep—5 wethers, one only a two year old—2 rams, one and two years old—12 ewes first shear—30 ewes from two to five and six years—26 of which produced 36 lambs, and raised 30 of them.

Weight of wool from Mr. W. Barton's notes.

9 fleeces full blood merino or 7-8	$58\frac{3}{4}$ *lbs.*
8 do. Arlington long wool cross	$73\frac{3}{4}$
8 do.	$55\frac{3}{4}$
8 do.	$66\frac{3}{4}$
8 do.	$56\frac{3}{4}$
8 do.	$62\frac{3}{4}$
49	$374\frac{1}{2}$

A total average, of above 7 5-8—the average of the 40 long woolled fleeces 7 7-8 lbs.—9 merino fleeces $6\frac{1}{2}$ lbs.

There were a few fleeces weighed in presence of some of the officers and members of the society.

	wt.	fleece
A Ram 2 years old, wt.	188 lbs.	10 lbs.
Ewe 1 year old, wt.	128	13
Ewe same age,	118	$11\frac{3}{4}$
Ewe do.	130	$11\frac{1}{2}$
Ewe do.	122	11
Wether, first shear,	128	11
Wether do.	120	11
Wether 2 years old,	185	8

It is to be understood that the whole of the wool was unwashed, and freed only from the gross tags. Samples of the above fleeces are sent you, which will be found to measure when the fibre is extended from six to nine inches—but take the very heaviest fleece we exhibit, and compare it with the Vermont fleece of $18\frac{3}{4}$* washed wool.

* This fleece proved to be of four years growth, as appears by a correspondence in relation to it between the editor of the American Farmer and the postmaster at Bennington, see American Farmer, volume 5th, page 213. The sheep is there stated to be a full blooded merino of the Livingston stock. It would be worth while, if practicable, to ascertain the increase of *each year*, where fleeces are thus left more than one year.—Ed. Am. Farm.

Does it not prove the necessity of our endeavoring to do so likewise? There is a practice prevailing with us, which, however congenial with the best social feelings, is nevertheless utterly at war with the prospect of reformation—I mean that of selecting the very finest of our lambs for our tables—a moderate forbearance, in the use of the second best for a time, or until our flocks are more uniform, would enable us to have them very fine, and still leave the best—the practice also of permitting the butchers to pick the fine fat ewes out of our flocks is extremely injurious, as in getting the best mutton they will also get many of the best breeders.* Therefore be particular in marking your breeders. To all such as will not find it convenient to introduce crosses into their flock, let me recommend the value and importance of using their best judgment in selecting not only from their own flocks, but as the celebrated Bakewell did in the commencement of his improvement, pick them up from the highway—perseverance will do for them what it has already done for him.

To the society I would now most respectfully and particularly appeal, as to a body of liberal and intelligent farmers, associating themselves not merely for individual benefit, whether in the expectation of rewards, honorary or otherwise, immediate; or relying on future advantages accruing from a mass of practical information which should naturally arise out of such an institution, but as having from principle and conviction taken on themselves (so far as the case will admit) the responsibility of a reform in the cultivation of the soil, and the improvement of our domestic animals, as essential to the more comfortable existence of a very large class of our farmers, whose situation, moderate settlements, and most industrious lives, preclude from advantages, to be derived only through the intervention of superior wealth and intelligence. I would take the liberty of suggesting, whether the most useful and economical way of diffusing information on the subject of husbandry (together with that respectability which would be added to our institution) would not be in acquiring a small, but well selected library, for the use of the society, and afford the presses of Winchester an opportunity of a weekly supply of agricultural matter for the benefit of their subscribers; is it not reasonable to suppose that a work of such apparent usefulness would have the effect of rewarding them through an increase of patronage for any trouble they might meet with in assisting the cause? The materials for the speedy amelioration of our live stock, are certainly to be found in the middle and eastern states, and are to be had on terms entirely within the capacity of this society, and such perhaps must be the course of our improvement, if at all—as their wealth has enabled them to import and improve both by breeding in and in, and by crosses on our home stock, some of the best stock in Europe.

Out of the numerous kinds of sheep in Great Britain, which they appear to have nicely discriminated and allotted to their various soils and situations, we have selected the Leicester or Dishley (alias celebrated Bakewell sheep) and South Down, which are to be had in admirable quality in Jersey and Delaware, and are by far the most valuable sheep for all those who do not intend raising wool on a large scale for the manufacturer —the latter of these breeds may be formed in our own country by a cross of any short close woolled ram on well modelled ewes. I know not whether they have the full blooded Teeswater to the Eastward, the heaviest breed of sheep in England; it would be well for us to possess so large a race—but I am of opinion we are mainly deficient only in the form of the animal, which enables them to carry much more flesh and fat with a greater economy of keep. I beg leave to refer you to the engravings of the Bakewell or Dishley, and South Down, as not a descriptive, or highly wrought, but a faithful picture of such sheep, if they maintain the same form now, as when viewed by me some years past in the state of New Jersey. The form of these sheep must strike the eye of every beholder, and will, I hope, make an impression of the great necessity of reform. 'Tis easy to raise sheep of great apparent size, a considerable body, on long legs* covered by loose long wool, may cut a conspicuous figure—but in real value take a flock throughout the short legged, long bodied, straight backed, &c. &c. carrying a close fleece of a fineness to suit the purposes of the breeder, the longer the better, for in that is to be shown the great skill of the shepherd, extending the fibre without injury to its other qualities. They are two to one in value.

March 4th, 1824. It had been my intention to have made this communication last summer, had not circumstances prevented—with some addition and amendment, which I am not able to do now—since that time we have learned, through the Farmer, that the Teeswater sheep are to be had to the eastward. Permit me to call your attention to the subject of cattle, as contained in the accompanying letter from the ex-secretary of the Philadelphia Society.

RICHARD K. MEADE.

From the Edinburgh Farmers' Magazine.

DIRECTIONS FOR MAKING COMPOST DUNGHILLS OF PEAT-MOSS, BY LORD MEADOWBANK.

[The following directions and observations, though relating to peat, a soil found rarely in Virginia, (if any where but in the Dismal Swamp,) would probably be valuable if applied to the more decomposed and already fertile vegetable soils, which our tide-marshes and alluvial swamps present.—ED. FAR. REG.]

Presuming that the directions for making compost dunghills of peat-turf, in a judicious manner, as ascertained in a pamphlet lately written by

* Mr. Barney, of Delaware, always selects his breeders *first*, and never permits the butcher or the purchaser of breeding stock, even to look at his *best* sheep with a view to the purchase of them. This, after all, is the way for the farmer to get the highest prices, because it gives him the best *stock* sheep.—ED. AM. FARM.

* Such was the character, in a considerable degree, of the wether weighing 185 lbs. and shearing 8 lbs. wool, mentioned at the close of the list. This sheep had height and length enough to have weighed with a proper form and close fleece 250, and have shorn at least fifty per cent. more.

Lord Meadowbank, will be of utility to many of your readers, I have sent you a transcript of a part of that pamphlet. I have only to add, that I have seen a compost dunghill, made according to his lordship's directions, which completely answered the purpose, by fermenting the peat-turf, and thereby reducing it into a situation proper to be applied as manure; which appears to me to be a far preferable method to that of reducing the peat-turf (or moss, as it is called in Scotland) to ashes.

I am, &c. A. S.

Let the peat-moss, of which compost is to be formed, be thrown out of the pit for some weeks or months, in order to lose its redundant moisture. By this means, it is rendered the lighter to carry, and less compact and weighty, when made up with fresh dung for fermentation; and, accordingly, less dung is required for the purpose, than if the preparation is made with peat taken recently from the pit. The peat taken from near the surface, or at a considerable depth, answers equally well.

Take the peat-moss to a dry spot, convenient for constructing a dunghill to serve the field to be manured. Lay the cart-loads of it in two rows, and of the dung, in a row betwixt them. The dung thus lies nearly on an area of the future compost dunghill, and the rows of peat should be near enough each other, that workmen, in making up the compost, may be able to throw them together by the spade. In making up, let the workmen begin at one end; and at the extremity of the row of dung, (which should not extend quite so far at that end as the rows of peats on each side of it do,) let them lay a bottom of peat, six inches deep and fifteen feet wide, if the grounds admit of it; then throw forward, and lay on, about ten inches of dung above the bottom of peat; then add from the side-rows about six inches of peat; then four or five of dung, and then six more of peat; then another thin layer of dung; and then cover it over with peat at the end where it was begun, at the two sides, and above. The compost should not be raised above four feet, or four feet and a half high; otherwise, it is apt to press too heavily on the under parts, and check the fermentation. When a beginning is thus made, the workmen will proceed working backwards, and adding to the column of compost, as they are furnished with the three rows of materials directed to be laid down for them. They must take care not to tread on the compost, or render it too compact; and, of consequence, in proportion as the peat is wet, it should be made up in lumps, and not much broken.

In mild weather, seven cart-loads of common farm-dung, tolerably fresh made, is sufficient for twenty-one cart-loads of peat-moss; but in cold weather, a larger proportion of dung is desirable. To every twenty-eight carts of the compost, when made up, it is of use to throw on, above it, a cart-load of ashes, either made from coal, peat, or wood; or, if these cannot be had, half the quantity of slacked lime may be used; the more finely powdered the better. But these additions are nowise essential to the general success of the compost.

The dung to be used should either have been recently made, or kept fresh by compression; as, by the treading of cattle or swine, or by carts passing over it. And if there is little or no litter in it, a smaller quantity will serve, provided any spongy vegetable matter is added at making up the compost, as fresh weeds, the rubbish of a stack-yard, potato-shaws, sawings of timber, &c. And as some sorts of dung, even when fresh, are much more advanced in decomposition than others, it is material to attend to this; for a much less proportion of such dung as is less advanced, will serve for the compost, provided care is taken to keep the mass sufficiently open, either by a mixture of the above-mentioned substances, or, if these are wanting, by adding the peat piece-meal; that is, first making it up in the usual proportion of three to one of dung; and then, after a time, adding an equal quantity, more or less, of moss. The dung of this character, of greatest quantity, is shamble dung, with which, under the above precautions, six times the quantity of peat, or more, may be prepared. The same holds as to pigeon dung, and other fowl dung; and, to a certain extent also, as to that which is collected from towns, and made by animals that feed on grains, refuse of distilleries, &c.

The compost, after it is made up, gets into a general heat, sooner or later, according to the weather, and the condition of the dung: in summer, in ten days or sooner; in winter, not perhaps for many weeks, if the cold is severe. It always, however, has been found to come on at last;* and, in summer, it sometimes rises so high as to be mischievous, by consuming the materials, (fire-fanging.) In that season, a stick should be kept in it in different parts, to pull out and feel now and then; for, if it approaches to blood-heat, it should either be watered, or turned over; and, on such an occasion, advantage may be taken to mix it with a little fresh moss. † The heat subsides, after a time, and with great variety, according to the weather, the dung, and the perfection of the making up of the compost; which then should be allowed to remain untouched, till within three weeks of using, when it should be turned over, upside down, and outside in, and all lumps broken: Then it comes into a second heat; but soon cools, and should be taken out for use In this state, the whole, except bits of the old decayed wood, appears a black free mass, and spreads like garden mould. Use it, weight for weight, as farm-yard dung; and it will be found, in a course of cropping, fully to stand the comparison.

Let it be observed, that the object in making up the compost, is to form as large a hot-bed as the quantity of dung employed admits of, and then to surround it on all sides, so as to have the whole benefit of the heat and effluvia. Peat, nearly as dry as garden-mould in seed time, may be mixed with the dung, so as to double the volume and more of it. Workmen must begin with using layers; but, when accustomed to the just propor-

* In order to bring on the heat more expeditiously in a compost made up in frost, a narrow addition of dung and peat has, sometimes, after the frost had gone off, been laid along the sides of the compost, scraping down a little the coating of peat upon it.

† In June 1796, a compost was formed, only 2¼ peat of 1 dung: it heated in July beyond the measure of a thermometer graduated to 110°. Part was allowed to stand, part turned with a half more moss. Three weeks after, (18th August,) the heat of the former had descended to 84°, while that of the latter had got up again to above 110°.

tions, if they are furnished with peat moderately dry, and dung not lost in litter, they throw it up together as a mixed mass; and they improve in the art, so as to make a less proportion of dung serve for the preparation.

The addition recommended, of ashes or lime to the compost, is thought to favor the general perfection of the preparation, and to hasten the second heat. The lime laid on above the dunghill, as directed, is rendered mild by the vapors that escape during the first heat.

Compost, made up before January, has hitherto been in good order for the spring crops; but this may not happen in a long frost. In summer, it is ready in eight or ten weeks; and if there is an anxiety to have it soon prepared, the addition of ashes, or of a little lime rubbish of old buildings, or of lime slacked with foul water, applied to the dung used in making up, will quicken the process considerably.

Lime has been mixed previously with the peat; but the compost prepared with that mixture, or with the simple peat, seemed to produce equally good crops. All the land, however, that it has been tried on, has been limed more or less within these twenty-five years.

The rich coarse earth, which is frequently found on the surface of peat, is too heavy to be admitted into this compost; but it makes an excellent top-dressing, if previously mixed and turned over with lime.

Peat, prepared with lime alone, has not been found to answer as a good manure. In one instance, viz. on a bit of fallow, sown with wheat, it was manifestly pernicious.

ON THE CONSTRUCTION OF ICE-HOUSES, AND STOWING AWAY OF ICE.

To the Editor of the American Farmer.

Sir—Having observed in a late number of the American Farmer, some remarks upon the convenience and utility of securing a plentiful supply of ice, for use through the summer season, I take the liberty to add a few observations upon the subject, which, if you think useful, you are at liberty to insert in your valuable journal.

As it would neither be convenient to myself, nor beneficial to the object we have in view, to enter upon an extended discussion of this subject, I shall at once proceed to remark, that the common manner pursued, by almost every one in putting up ice, is to throw it promiscuously into the house, and then employ laborers to break it into small pieces. In this manner of securing it, numberless interstices are formed by the angles of the pieces after they are broken, which being filled with air, operate of course through the season, to promote the decay of the ice, and greatly accelerate its dissolution.

The manner which I have pursued, and which I strongly recommend to the observance of your readers, is, to cut the ice as nearly into squares as can conveniently be done, and when conveyed to the house, lay these down carefully, in regular layers, taking care to break them as little as possible. As soon as the first layer or stratum is completed, fill up with fine ice all the crevices, which the angles in the pieces may have occasioned, then sweep the surface clean, from all small fragments of ice, so as to leave a smooth clear floor or surface, to commence your succeeding stratum or layer upon; and thus proceed, until the house shall have been completely filled. In this manner, I have found that one-third more ice can be stowed in a given space, than could be put into it by the ordinary mode of pounding; and as there will not be the smallest crevice throughout the whole mass, if the plan here recommended is properly executed, it is confidently asserted that the ice will last *double as long* as under the common mode of securing it.

Every ice-house should be provided with a drain to carry off the drippings throughout the warm season, unless the bottom be an open porous sandy soil; as nothing is so fatal to ice as moisture. This drain should be so constructed as not to admit air; else a constant current of warm atmosphere will be drawn to the bottom of the ice, which will rapidly destroy it. The house, which the writer of these remarks has erected, is of the most simple construction, and a similar one may be built by any farmer, for an expense not exceeding $30. It has been filled in the manner here recommended, and has not been without ice since it was first stocked, and at this time contains a considerable quantity, notwithstanding the most profuse use was made of it, by two families, during the whole of last summer.

The following plan is recommended, in the construction of ice-houses: Dig a pit on the north or north-west side of a bank or hill, 18 feet square, and about 14 feet deep on the upper side, to which depth, the pit may be raised all round, by the dirt being thrown to the lower side; build in this pit a house of white oak logs, so as to leave a clear space between the outsides of the house and the wall of the pit, of about two feet. If the bank is of hard clay, it will need no stay: if it be not of clay, or hard firm soil, it must be stayed by pieces of plank propped against it, from the outsides of the logs, so as to prevent its covering the space between the logs; and this bank should be filled all round with straw, and the insides of the logs boarded up, so as to present a smooth even surface; this will leave the inside of the house about 12 or 13 feet square, which will be sufficient for any family.

The drain from the bottom of the house, should be placed on the lowest side, to which a sufficient fall ought to be secured from all parts of the foundation. The drain should be formed by stone, so laid as to afford an opening for the water readily to pass off, and then covered up with earth, taking care to allow to it a sufficient fall; and then its termination be covered slightly with earth, so that no air can pass up, whilst the moisture may gradually soak through. Lay at the bottom of the house, sleepers, so as to raise the planks to be placed upon them, about one foot from the ground, and upon these planks lay your first strata of ice, as is here before directed.

After raising your house with logs, (as here recommended, to the height of about 14 feet,) build another house over it, with logs, to be placed upon the surface of the ground, at the outer edge of the pit; raise this house about three feet high, upon which place your roof, and from the inner logs which inclose the ice, to the outer ones, which support the roof, nail planks, and stow the whole space under them with straw—you will thus have an ice-house surrounded on all sides with a thickness of about two feet of straw. When the ice is put away, cover the whole with a suitable thickness of straw, which should be removed once or twice in the course of the summer, as it becomes wet, and replace it with a fresh dry covering. By pursuing these means, you need never be without a plentiful supply of ice at all seasons.

P. E. T.

From the Edinburgh Farmers' Magazine.

AN ESSAY ON THE PROPER SIZE OF FARMS.

This will best appear from observing the *effects* of the different classes of farms as at present existing, and which may be arranged under the following heads:

I. Of farms altogether under *tillage*.

II. Of farms altogether in *pastures*.

III. Of farms *partly in tillage, and partly pasture*.

Head I.

Of farms altogether under *tillage*, yet including as much pasture as may serve the milch-cows for the family use alone.

These again may be subdivided under the following classes:

1*st*, Of small farms in the occupation of *mechanics*.

2*d*, Of small farms in the occupation of *husbandmen*, having no other profession.

3*d*, Of *two* or *more* farms contiguous, cultivated by one farmer.

4*th*, Of *several* farms *separated* from one another, but in one man's occupation. First, then,

Of small farms in the occupation of mechanics.

These are generally to be met with in the vicinity of towns or large villages; there are some examples of them also in the smaller villages scattered over the country, in which the wright, the smith, the webster, or the sutor, have their bit of land.

The husbandry of all these, without a single exception, is bad; the more inexcusable, when it happens to be in the immediate vicinity of a populous town, where, from market and manure, they ought to be in the best state: but there is an inherent vice in this system, which no situation can counterbalance. For agriculture, in such hands, can never be more than a secondary object, or rather a by-job altogether: But, unhappily, this is not all the mischief; for even their primary profession suffers in their unavoidable distraction of attention between the different occupations: And thus, from commencing their agricultural career, as bad husbandmen, they commonly dwindle down, in the end, to be sorry mechanics likewise.

It would, however, be wrong to prohibit this species of husbandry. Why should a man be hindered from giving vent to his folly in this line, as well as in any other. His time, to be sure, is very ill bestowed on such a speculation; but it would be worse *spent* in the *tavern*, on the *turf*, or in the *cock-pit;* and if there be any truth in the notion, that the *health* of such people is promoted by rural operations, it may compensate in some degree, to the state, what it thus loses by their wretched cultivation.

There are, indeed, some examples of farms on a larger scale, that are occupied by *townsmen*, in which the cultivation is by no means bad. Some people, however, are ill-natured enough to remark, that the original profession declines in proportion as the farming advances: but the consideration of this is foreign to the present question.

2. Of *small* farms in the hands of *husbandmen having no other profession.*

By a farm of this description, I mean one of a *single ploughgate* of land, containing from 30 to 50 acres.

In this situation, the farmer cannot afford to *lie idle*, as it is termed; he must be a laborer himself, and is commonly the hardest wrought laborer on his farm. He is indeed the only able-bodied man about his *town;* his servants consisting of a raw lad to assist him in the field-operations, and a boy to take care of the cows. In winter, he may have an old man, supernumerary, to assist him four or five months to thrash out his crop; but, at all seasons, he receives much assistance from the female part of the family. The women are ever kept in full employment. They *redd* the barn to the old man; they fork the dung, and spread it along with the lad; they muck the byre, and fother the nolt with the boy; they carry the seed-corn to the *gudeman;* and, in company with the *gudewife*, they weed the lint, and dress it; and besides spinning, and the daily operations of the *dairy*, and making of the *porridge* and *kale*, they have the occasional drudgery of the washings to perform too. Nothing, indeed, can exceed the industry of this part of the family, but the cheerfulness of their disposition, and their unaffected simplicity of manners.

With regard to the agriculture of this plodding class of farmers it depends very much on the practice they have been educated in. No improvement almost was ever known to originate with them. They have even a reluctancy to adopt any that may be suggested to them. This does not arise, however, from any perversity of disposition or failure of intellect; but it is the natural consequence of their confined situation, and scarcity of transactions. They cannot afford to mix with the world from curiosity: even their indispensable absence from home, on account of business, is peculiarly inconvenient and expensive, as it lays the full half of their home-operations at a stand, while the little business they have to transact abroad is not full employment for the time.

There are, however, many examples of good cultivation in this class, (in well established modes of good cultivation they are indeed excelled by none); but it will always be found, that the most intelligent of them or those who have had, from some specialty in their circumstances, an unusual intercourse at an early period with society; or who, living in the vicinity of a great town, have hence acquired, at little expense, a knowledge of mankind, and of the principles of improvement, which in a remote situation, in their limited sphere, they never could have attained.

Whenever our country is so completely cultivated, that there will not remain a single improvement that can be made, either by inclosing, draining, watering, &c., or in cattle, implements, or rotation, then may it be laid out into such small farms, and consigned into the hands of these little tenants, who will be able, perhaps, without any great loss, to retain the soil in fertility. Such arrangement may be even necessary, from a regard to the morals of the people; as, from the dissipation which will naturally accompany such a state of prosperity, there would be no class of men so apt, from their circumstances, to retain the simplicity of manners and laborious industry of ancient times. Even at the present day, they may be placed in the vicinity of great towns, where the land is already, for the most part, in an improved state, as their habits of industry and temperance would, for some time, prove a barrier against the spread of the enervated licentiousness of city-depravity; though it might still be necessary, from time to time, to renew the race from more remote parts, in proportion as the present possessors become contaminated with the vices of a more luxurious life. This change of tenantry would be of advantage, were it mutual between the parties: for, if those who have been living for a series of years in the neighborhood of a great town, were removed to a more remote situation, their more intelligent ideas in their profession would operate to the more rapid melioration of the less improved lands on which they might choose to settle, while they would lose the habit of dissipation, from being less in the way of temptation to indulgence.

At present, the produce brought to market from small farms is always less in proportion, than from farms of a larger size: because a greater proportion of it is consumed at home, by the more proportionably numerous stock of unproductive cattle; an inherent evil in little farms, which no genius in the occupier can obviate: and, in general, there is even less produced on the ground, from the circumstances before stated, with regard to the abilities of the husbandman himself. With regard to the effect of small farms on population, that will best appear from the next subdivision.

3. Of two or more farms lying *contiguous*, occupied by one farmer; being the general means by which *great* farms have originally been formed.

Though this system of letting lands has ever been a grievous subject of lamentation with half-witted politicians, it has nevertheless, in practice, been found to be the most beneficial to the country, and still continues to add to the general prosperity.

When two or more farms are conjoined, the following effects arise: 1. The *expense of labor is reduced*, in so far as the peculiarities in the soil in one, are contrasted by those in another farm; so that when the land is not in a condition of being labored in one, it may with propriety be labored in another; as in the example of one of the farms being of a dry soil, and the other of a wet; and which is commonly a conducing reason for the conjunction. Even where the soil is all of the same nature, there arises an advantage in the laboring of a great farm, from the concentring of the strength of men and horses at any particular operation, by which it is got finished in proper case, with less risk of being spoiled, from the uncertainty of weather, &c. 2. The *expense of house-keeping* is reduced, in proportion as there are fewer families of farmers to maintain. 3. The farmer, having more business, is more abroad in the world; is conversant in a higher line of life; and thus, having more opportunities of information, he, in fact, becomes better informed; and as he has, 4. The *profits* of a *greater quantity* of ground in his hands, he is thence more able to introduce an improvement in practice or in stock, from another quarter, or better enabled to propose it himself, from his own observation and experience.

The real produce of the lands becomes thus augmented; and as there is less of it consumed at home, (there being fewer men and horses to maintain), a still greater proportion goes to market.

The *population* on the land is also augmented; for although it be true, that the common operations of the farm are conducted by fewer hands, yet there is always some extra work going forward in the various operations of improvement; such as, in hedging, ditching, levelling, draining, building, &c. which the little farmer never would have thought of, or never have performed. The great farmer also excels the little tenant in a circumstance, which, more than any thing else conduces to the population of the country; which is, that the *greater part of his servants are married, and have families of their own:* and this he chooses, not from any affectation of patriotism, but from a principle of more effective influence—a regard to his own interest; as he finds, that a numerous household of unmarried servants are very unmanageable, and that he is better served with sober married hinds, who board in their own houses, at less expense, and more to their satisfaction, as well as his own.

The following state, in regard to this point, of a farm in the vicinity of Edinburgh, consisting of about 280 Scottish acres, and which, prior to 1736, was in three farms of two ploughgates each, and which has since been united into one, shows this in a more explicit manner.

1735.		1793.	
Families of farmers	3	Family of the farmer	1
Ditto of cottagers	6	Families of cottagers	14
Total families	9	Total families	15
Horses	33	Horses	16
At this period, the increase from the married servants, was not sufficient to keep up the number of unmarried servants, who, of course, were obtained partly from the neighboring villages; being sons of weavers, tailors, &c.		At the present period, the increase from the married servants does much more than supply the population necessary. Their sons and daughters are therefore sent to supply the neighboring towns, or to *the smaller farms in the neighborhood which cannot supply themselves!* There are also at this time, four young men from this farm at sea.	
Rent about 230l.		Rent 636l.	

As to the question, *How large ought a farm to be?* I can perceive no bounds, in point of propriety, except those which nature has set to the genius of the farmer, and providence to his fortune; for the larger that the farm be, if the tenant has capital, and abilities answerable, the better it will be, in every respect, to the community; as not only more produce is brought to market, but actually more is produced, from the superior advantages the great farmer enjoys, of being more able to make improvements, because more wealthy; but also better inclined to do so, from being more intelligent. We even see, that the population of a country thus occupied, is augmented, from the circumstance of his interest being concerned, in giving the preference to married servants, instead of lads and boys, and superannuated men, with which the small farms are peopled. That he does not employ the whole progeny of these hinds, is a favorable circumstance to the public, as they serve as an excellent nursery for the supply of the mechanical branches, which not only cannot be recruited from a country laid out in small farms, but are themselves drained of their youth, to keep up the population of that unproductive system.*

Instead, therefore, of inquiring what ought to be the size of a farm, an assize ought to be held on the judgment of the farmer, and the capital he is able to command; for although it may be remarked, that the powers of the mind, even in the same person, expand and contract, according to the situation in which he may for some time be placed, yet there can be no doubt, also, that there are people whose genius far surpasses the general run, in whatever circumstances they may be placed. Thus, while it would require a man of considerable abilities to manage, in the best manner, a farm of 300 acres in tillage, I should suppose, that were the vast abilities of a *Fox*, or of a *Pitt*, to be concentred on agriculture, with an inclination to the profession, they could, with equal ease, manage a farm of ten times the extent: at least, those who undertake such a charge, and do justice to the subject, might be considered, in agriculture, as those two great characters are in politics, among the most enlightened of their compatriots.

A farm in the vicinity of a great town, requires more abilities to manage, in proportion to its extent, than a farm in a more remote situation; because the branches of operation are more minutely divided, and the sources, from which the revenue is obtained, flow in more various channels; while the general economy of the whole is regulated by more uncertain and variable principles.

4. Of *several* farms in the possession of *one* farmer, lying at *a distance* from one another.

In this system, the advantages are not altogether so great as when the farms are contiguous: For, 1*st*, The contrast in the soil gives no advantage in the labor; nor can the strength of the whole be concentred on one object: of course, a greater expense in labor is incurred. 2*d*, As the master cannot oversee the whole personally, he must delegate his authority in part to an overseer, which seldom turns out so effective. But, in other respects, the advantages are nearly equal; and in population it is superior; for more people are required to do the same work. The profit, of course, will be diminished; but as the farmer will be more in the practice of traversing the country, he will naturally become more intelligent, and thence carry on his plans more judiciously.

* It is curious to observe the cant of declamation (for depopulating the country) which has, for these last forty years, been kept up against the uniting of the small farms, which has taken place chiefly in that period, which has not only been an æra of great agricultural improvement, but the population, from actual investigation, has increased, in Scotland, near 300,000 souls, or about one-fifth of the whole.

Head II.

Of farms altogether in PASTURE, *including a small proportion of tillage, for raising corn and potatoes for the residenters.*

These may also be considered under the same subdivisions as in the former head.

1*st*, With respect to mechanics interfering with this system, there is hardly an instance, though it would be much more for their advantage, if they converted their pitiful possessions to the maintenance of a milch cow, or the rearing of a young beast, than, in their present wretched system of tillage, oppressing themselves, and disgracing the country. But, for this purpose, it would be necessary that their patches were inclosed: but that would be by far too great an exertion for their genius; and so I shall leave them to their own mismanagement.

2*d*, Of *small* pasture farms in the occupation of tenants having *no other occupation*.

There cannot well be a very small farm of this description, as the attention required would not be sufficient employment, neither would the profit to be derived be a sufficient recompense for constant attention. They must necessarily, therefore, be of greater extent than the small arable farm, where there is always abundance of employment to the little tenant; and although there may be little recompense to him as a *master*, yet he is generally understood to be sufficiently remunerated for the labor which, as a *servant*, he bestows upon it.

The same circumstance which promotes the prosperity of a corn farmer on an arable farm, and the consequent prosperity of the country, will, I am persuaded, operate in the same manner upon a cattle-farmer in a pasture farm, viz. that the larger that the concern be, if the tenant has abilities answerable, the more enterprising will he become, and the country will the more speedily be improved in the breed of cattle, and melioration of pasture lands.

3*d*, Of *two or more* farms lying *contiguous*, in the occupation of one tenant.

That the tenant in this situation will be more wealthy and more intelligent, and hence, being more enterprising, will be more beneficial to the country, has already, in the foregoing article, been noticed; in addition to which, the following remarks occur.

A man will be able to manage a pasture farm of greater value and greater stock, on a rich soil, than on a poorer one, which must be more extensive to yield the same produce, and will therefore require more exertion to oversee. The quantity of land and quantity of stock that a farmer may have abilities to manage in a pasture farm, may be vastly greater, than in a farm under tillage; as there are fewer servants to oversee, and as the process of breeding and feeding cattle is much less complex than that of raising corn.

The effect on population, of uniting two or more pasture farms into one, will be much the same, as formerly stated, with regard to farms in tillage; for, although the tenant may be enabled to keep fewer herds, yet he will naturally choose that these should be married men, boarding in their own families: even were this to produce no increase of population, it ought to be held as beneficial to the country; for the great farmers' herds have a better chance of getting full employment, than in a small farm tending a small flock,

"The herd diminutive, of many hues;" THOMSON.

where they are little better than half idle: for a population of idle people ought to be exploded; as not only are the faculties of these people themselves locked up for want of exertion, but the money which their maintenance requires, is thus diverted from the channels of enterprise and improvement into which it might otherwise have flowed.

4th, Of *several* pasture farms, at a *distance* from each other, in one tenant's occupation.

The effects in this case are almost the same as if the farms lay contiguous, provided each separate farm has all the varieties of pasture, and proper shelter for the cattle; but if this is not the case, it were better for the farmer (and for the public) that they lay conterminous to one another, as they thereby could afford accommodation, to the mutual advantage of the whole. So far, also, as loss may arise from the master not being able to superintend the whole, so far will there be a disadvantage in having distant farms in pasture, as well as distant farms in tillage; but, on the other hand, as was before observed, the farmer himself will become more intelligent, in proportion as he has to traverse a greater range of country, from which he will the more readily introduce or make improvements in the breed or management of his flock.

Head III.
Of arable and pasture united.

Whatever has been said respecting the *size* of farms, in the two former heads, is equally applicable to this; the larger that the farms are, the more intelligent and enterprising will the farmer himself be; and hence, from his more spirited and judicious exertions, the community at large will derive a greater advantage.

This mode, or system of farming, is the most judicious of the whole, as it promotes the interest of all parties concerned, the proprietor, the tenant, and the public at large, more than either of the two modes separately. It promotes the interest of the proprietor, by affording him a greater rent: it promotes the interest of the tenant; because he will be able to manage a greater extent of land, than in a farm wholly in tillage; and he will have more intercourse with the world, than in a farm wholly in pasture; and hence, performing more business, and being more enlightened, he will become more wealthy. Finally, it promotes the interest of the public; because a greater proportion of the produce will be brought to market, and even a greater crop produced. This arises from two causes: 1*st*, there will be fewer unproductive cattle to eat up the produce at home: 2*d*, The lands being alternately in tillage and in grass, they will be kept in better condition; and the crops of corn, and of hay or pasture, will be more luxuriant, and of a better quality.

With respect to *population,* this system is unfavorable in one case, and favorable in another. It is unfavorable in the case of converting a farm, that had been wholly in tillage, into part tillage, and part pasture; for pasture land always requires fewer people to manage it, than lands in tillage; but for the same reason, it is favorable to, or increasive of population, when pasture lands are converted to the production of grain. In a great proportion of the best lands of England, it would be highly for the advantage of all parties, that this system were adopted, instead of the grazing system, which prevails without variation. In Scotland, however, the case is different; there, the greater part of the arable lands, which formerly were kept wholly under the plough, have been most judiciously improved, from the introduction of this alternate system, and which has, to a certain extent, diminished the number of people employed in agriculture, greatly to the mortification of the gloomy-minded declaimers against the present times, who, in the blindness of their rage, denounce the uniting of small farms as the cause of this mistaken national calamity. But, even were this notion to be well founded, (and it would not be difficult to show that it is not,) yet surely it is not solely the *numbers* of people employed in any profession, that ought to render them respectable in the state: regard must also be had to the *ingenuity* with which they are actuated, and the *industry* with which they carry on their operations. People, not judiciously employed, are little better to the state than if they were not employed at all.

H.

For the Farmers' Register.

ROUGH FIELD NOTES.

No. I.

Chesapeake and Ohio Canal.

This canal is one of the most interesting, and, in point of construction, one of the greatest works in our country. It was commenced ten years ago; and packet boats can now ascend to Williamsport, rather more than 100 miles above Washington. It leaves the head of tide-water at Georgetown, and will terminate somewhere on the Ohio near Pittsburg. The whole length, when completed, will not be less than 340 miles. This route may be divided into three sections: first, the eastern, from Georgetown to near Cumberland, 187 miles; second, the section on which is the summit level, from Cumberland to the north of Casselman's River, 71 miles; and third, from the last named place to the Ohio, 85 miles.

The rise on the first division is 635 feet; the whole lockage on the second, 1961 feet; and the fall on the third, 619 feet; making the lockage of the whole canal 3215 feet. On the second division, there will be a tunnel, of rather more than 4 miles long, under a ridge of the Alleghany, 860 feet in elevation. What a stupendous undertaking! If ever completed, to see it will be worth a trip across the Atlantic.

From Georgetown the canal rises, by a rapid succession of 5 locks, 35 feet. At Harper's Ferry it attains an elevation of 255 feet above tide, by means of 32 locks. The locks are all built of stone, hewn on the face, 100 feet long and 15 feet wide in the clear, and are from 6 to 8 feet lift. The canal itself is 60 feet wide at water-surface and 6 feet deep. For a few miles above Georgetown, the dimensions are even greater. The towpath is 10 feet wide at top. The embankments of the part now in use have become solid and firm. The canal slope of the embankments is covered, for the greater part of the way, with broken stone, measuring not more than an inch or two cube, to prevent abrasion. The stone is found to preserve the banks well, and will be used for this purpose throughout.

After leaving Georgetown, until the principal falls are passed, the banks on either side of the Potomac crowd on the river, and the canal clings along the northern bank with frequently perpendicular bluffs of rock, 50 feet high one side, and stone walling on the other, to protect it from the river. The valley of the river, however, soon widens. The receding hills give more room for the canal, and a better location is obtained on a gentle slope, free at once from the heavy cutting or walling. The hills frequently again approach the river, and again there is very heavy work. Such are the general features of the location from Georgetown to the Point of Rocks, at which place the Potomac breaks through the first range of the Blue Ridge, under the appellation of the Catoctin Mountains. From this point to Harper's Ferry, the canal and Baltimore and Ohio railroad run side by side, frequently along the side of precipitous hills, with rocks hanging a hundred feet above them.

At several places below the Point of Rocks, the canal cuts through the beautiful Potomac breccia, the material of the columns in the hall of congress at Washington: in fact, those columns were taken from this very place. There was a long suit between the canal and railroad companies, with regard to the right of way between the Point of Rocks and Harper's Ferry. The canal company, being the first chartered, and believing that the railroad would seriously injure their interests, strenuously opposed the passage of the railroad. The suit was decided against the railroad company; but the matter was afterwards compromised, and, in consideration of a certain sum of money, the right of way was granted to the railway.

The Monocacy and Catoctin aqueducts, across streams of the same names, are the principal structures below Harper's Ferry. The former consists of 7 arches, each about 55 feet span, the latter of 3 arches. They are built entirely of stone. A part of the Catoctin aqueduct fell down about June last, and they are now engaged in repairing it.

Harper's Ferry is situated in the fork of the Potomac and the Shenandoah. You have heard much of the scenery in its vicinity. My anticipations were very great, but they were not disappointed. I reached it a little after dark, and saw it both by day and moon-light. On approaching it from the Point of Rocks, the scenery combines both beauty and sublimity. The Blue Ridge is soon passed, and the traveller is enclosed by mountains—the river falling and tumbling over rocks—the quiet canal calmly winding its way in graceful curves—the long train of engine and coaches hurrying rapidly past—the high and rugged mountains on either side at times presenting to the eye nothing but naked rocks, at others covered with all the tints of autumnal foliage, and the setting sun with its reflected light streaming along the bosom of the water, all combine to furnish a scene truly enchanting. A little farther, and the course of the river becomes more and more intricate; its egress can no longer be traced, nor can the eye find where it enters the barrier of mountains. On reaching Harper's Ferry, the effect of the scenery is still increased: up the Potomac or down the Potomac, or up the Shenandoah, all is beautiful.

Alexandria Canal and Aqueduct.

The proper termination of the Chesapeake and Ohio canal is undoubtedly at Georgetown; but both Washington and Alexandria have determined to extend it through their respective bounds. To this end, Washington has expended a sum of $225,000 in converting what was once an ugly and filthy creek, into a broad canal, which extends through the lower part of the ground of the corporation, to the east branch of the Potomac. The Alexandria canal is on the south side of the Potomac, and is to be united to the Chesapeake and Ohio canal, by means of an aqueduct, now in the course of construction, at Georgetown. Think of a navigable canal being carried across the tide-water of the mighty Potomac! The aqueduct will consist of nine spans of about ninety feet each. It was commenced four years ago, and has heretofore proceeded slowly. They seem now, however, to be pushing the work with more energy; and it will not be long before the canal boats will be gliding across, at an elevation of 35 feet above the surface of the water. One abutment and 3 piers are now finished; 2 other piers are above high-water, and 3 have yet to be founded. The masonry of the abutments and piers does great credit both to the builders and superintendents, and the coffer-dams and fixtures, (accounts of which have been published in some of the European journals,) show great professional knowledge on the part of their engineers. The piers are founded on solid rock, as much as 35 or 40 feet below the surface of the water. A steam engine is used to pump the water from the coffer-dams.

As much, however, as I admire the execution of the aqueduct, so far as it is finished, and, indeed, as noble and magnificent as is the undertaking, I still more wonder at the consummate folly which throws away hundreds of thousands in constructing a canal by the side of such a river as the Potomac. A striking comment on the wisdom with which this work was conceived, is the fact that a steamboat plies almost hourly between Georgetown and Alexandria, and the fact, that I saw at the wharf of Georgetown, at the very head of this canal, a full-rigged ship of not less than 350 or 400 tons. It is attributable to the same petty jealousy, no doubt, which is so often found throughout our widely extended country, causing immense sums to be sometimes expended in vain, and, at others, preventing the expenditure of a cent, where thousands might be expended with profit.

Baltimore and Ohio Railroad.

This work was commenced in 1828, and is interesting in as much as it was one of the first railroads in this country—and because its company has done more than any other to advance and improve the railway system. Almost every different kind of superstructure has been tried, and experiments made without regard to cost, in order to attain that which was really best.

The railroad leaves the head of Pratt street, in Baltimore, and passes across the country for 9 miles to the Patapsco. In this distance there is much heavy work—excavations and embankments as much as from 40 to 70 feet. In this part of the route is the Carrolton viaduct, well worthy of notice. It is built of hewn granite, consists of two arches, one of 80 feet span across Gwynn's Falls, and a smaller one of 20 feet span for a roadway. The whole length is 312 feet—from surface of water to top of the parapet is 52 feet, and the width between the parapets is 26 feet. The cost of this viaduct was $53,000.

After striking the Patapsco, the railway follows the valley of that river to its head, about 40 miles from Baltimore. For this distance it follows closely the windings of the river, and for nearly the whole way constitutes a shelf along a precipitous hillside. It crosses the Patapsco once, about 15 miles from town, by a stone bridge, 375 feet long, and consisting of 4 arches, two of 54 feet span, and two 21 feet. This bridge is a handsome structure of unhewn granite of the best quality, an abundance of which is found in the vicinity. A small quantity of granite was carried from this place to Washington, for the new Treasury buildings; but much the larger portion of the granite for that immense pile came from James River. These 40 miles are a continued series of curves, and curves too of small radius; some of the curves having a radius of only 395 feet. The evil of bold curvature in a railroad was not so well understood when this road was built. The company is now actively engaged in altering their location in many places, and grading a new way in order to avoid some of their worst curves. In one place they will have to cross and recross the Patapsco, making two expensive bridges.

From the head of the Patapsco to the head of Bush creek, a tributary of the Monocacy, a distance of four miles is occupied in crossing Parr's Ridge. This is the dividing ridge between the waters of the Patapsco and those of the Potomac, and is 813 feet above mid-tide, at Baltimore. It is ascended by two inclined planes, the first 2150 feet long and 80 feet high, the second 3000 feet long and 100 feet high. On the top there is a level 600 feet in length, intended for the location of the machinery for working the planes. On the opposite side, the road in like manner descends from this ridge by two inclined planes, the first being 3200 feet long and 160 feet high, the second 1900 feet long and 81 feet high. These planes are at present worked by horse-power, and are an annual expense of $25,000 to the company. The day I crossed this ridge, each coach, (and there were 3 coaches of the largest class,) was drawn by 6 white horses. These planes might have been avoided by grades of 80 feet to the mile, and I am glad to see that the company is now engaged in making that alteration. The planes are all straight.

From the western foot of Parr's ridge, the road follows down the valley of Bush Creek, to near its junction with the Monocacy. It then crosses this stream, and after running down its valley a mile or two, strikes across the country to the Point of Rocks, on the Potomac. This portion of the road has less bold curvature than any other. though there is no part of it where the curves are not very objectionable. The Monocacy is crossed by a bridge 350 feet long, of 3 spans 110 feet each. The piers and abutments are of stone, but the superstructure of wood. After crossing the Monocacy, there is a branch to Fredericktown, 3 miles long. From the Point of Rocks to Harper's Ferry, as I mentioned before, the railroad runs up the valley of the Potomac, along side of the canal. At Harper's Ferry it connects by a bridge with the Winchester road, penetrating 32 miles up the finest valley of Virginia. This bridge consists of stone piers and wooden superstructure, on the plan of the celebrated Schaffhausen bridge. It consists of 6 spans of 140 feet each. It is now much out of order and considered unsafe for locomotives. The Winchester road leaves Harper's Ferry on trestle work, which is planked over, and forms by moonlight one of the most beautiful promenades I ever saw, running immediately up the middle of the Shenandoah valley, with high mountains towering on either hand.

The valley of the Patapsco furnishes scenery singularly wild and interesting, and the ravine of Bush Creek not much less so, with which the rich and highly cultivated country, through which the road passes from the Monocacy to the Potomac, furnishes a striking and beautiful contrast. So that there are few roads on which you can travel the same distance with such delightful scenery. From Baltimore to Harper's Ferry, the road is 81 miles long, and has cost about $28,000 per mile. The grades on this road, with a few exceptions, are less than 30 feet to the mile.

From Baltimore for 58 miles there are two tracks laid; for the remaining distance, only one has been yet put down. One of the tracks for 30 miles consists of iron plates $2\frac{1}{4}$ by $\frac{5}{8}$ inches on stone rails; all the rest consists of wooden sills, bedded every four feet on broken stone. Into these sills is keyed a rail 6 inches square, and on the rail a plate $2\frac{1}{4}$ by $\frac{5}{8}$ inches. The stone and iron track is used as little as possible; much of the iron has been taken up, and cross ties of wood put on the stone. In a few days they will begin to put new superstructure throughout, on a plan which will be both strong and lasting. They will make their road-bed in the first place of broken stone; on this will be bedded longitudinal string-pieces, on which will be put cross-ties every 3 feet. These ties will support a T rail, weighing 41 to 45 lbs. per yard. It is a source of no small degree of pleasure and admiration, to see a company that has expended such large amounts of money uselessly, and worse than uselessly, still pushing boldly on, gathering experience from its errors, and prosecuting its noble undertaking with an enterprise and energy that must ensure success. The company manufactures its own engines and cars, and has very extensive workshops in Baltimore. The company has my best wishes; it has done much for the cause of internal improvement, and has uniformly exhibited a degree of liberality and enterprise not often met with.

From the Practical Farmer.

CLEANING NEAT CATTLE.

The following we translated, and we would invite the attention of farmers to the subject. Our German correspondent is the right kind of a man.

He gives his notions well confirmed by experience.—*Editor.*

Xenia, Ohio, June 14th, 1838.

MR. EDITOR—Allow me, through the "Farmer," to say a word to my fellow farmers on, what seems to me, an important subject. In this country, you will seldom find a curry-comb and hand brush in the cow-stable; but I consider them indispensable in the cow-stable, as in the horse-stable. Why farmers do not curry and brush their cows, I know not, unless it be that they think cleanliness is not so necessary to the cow as to the horse.

But if we will, for a moment, consider the evils arising from this neglect, the importance of keeping cows clean must strike every reflecting mind. It is well known that no animal, neither horse nor cow, can be healthy, unless *the insensible perspiration goes on regularly*, and this can never be going on if cows are kept in a dirty stable, and no pains taken to rub off carefully the dirt or matter which obstructs the vessels or pores of the skin.

Wherever cows are regularly curried and rubbed they are invariably stronger and in a healthier condition; not liable to *cutaneous* and other diseases; and from experience I know they yield more milk, and that too of a better quality—a cleaner milk, richer cream, and sweeter butter, necessarily follow.

I make it a practice to curry my cows once a day very carefully—I never suffer any dung to stick to their coats—it looks bad, and injures the cows. This useful animal does not deserve such *dirty treatment.* Give them litter sufficient, and remove the dung regularly, and this part is accomplished.

Many of our farmers seem to think that in order to have healthy and good cows, you need only feed them with a sufficiency of food; however, I am fully convinced from experience, that cows may be well supplied with food, still they will not be as profitable as they would be if kept perfectly clean, and free from all kind of dirt and matter obstructing perspiration, as above stated; besides this, if cows are kept perfectly clean, they will thrive upon a less quantity of food.

Cows are often subject to have swollen teats and udders, as well as other excrescences. These may be prevented if the parts be occasionally washed with warm water. The udder and teats should be carefully washed immediately before the cow is milked. It has been well said by Loudon: "Go to the cow stall—take with you cold water and a sponge, and wash each cow's udder clean before milking; dowse the udder with cold water, winter and summer, as it braces, and repels heat."

DAVID HEYMACKER.

KENTUCKY CATTLE.

The following are prices obtained for a part of a stock of fine blooded cattle, belonging to the estate of the late General James Garrard, as we find it in the Paris (Kentucky) Citizen. The list embraces all the thorough-bred cattle offered for sale.

Exception, sold to Brutus J. Clay & Co.	$1830
Eclipse, a calf, George M. Bedford - -	688
Cherry, a cow, to Gen. John Pratt - -	1125
Matilda, to Brutus J. Clay & Co. - -	920
Fanny Kemble, a calf, to Kemus Payne	880
Maria, a cow, to Wm. Gray - - - -	551
Melvira, and calf, to same - - - -	1005
Marchioness, yearling heifer, W. C. Goodloe	407
Moss Rose, to W. G. Clay - - - -	375
Tulip, old, to Thomas Y. Brent - -	130
Beauty, to John and Joseph Collier -	476
	$8187

Below is a list of some of the fine mixed bloods:

Lady Morgan, yearling heifer, sold to W. Scott, for - - - - - - -	$550
Snow drop, a calf, to N. P. Rogers -	325
Lucilla, yearling, to James Batterton -	340
Julia Jackson, to Enoch Kirby - -	195
Rosetta, a calf, to same - - - - -	155
Lily, to John Collier - - - - -	190
Josephina, to Moses Ryan - - -	205
Red Beauty, to same - - - - -	375
White Lily, to John Desha - - -	105
Young Nell, to John Graves - -	140
	$2580

Amounting in all to - $10,967

From the Silk Grower.

SILK-CULTURE.

Having fed a small number of silk-worms the past season, and having, as I suppose, succeeded well, I send you a brief account of my fixtures, feeding, &c. If you think my experience will in the least degree aid the good cause in which we are in common engaged, you are at liberty to publish it. My cocoonery in 36 feet by 18, two stories high, lathed and plastered, with a chimney in each end, and a cellar under the whole. The building is substantial and well finished. It has 28 windows and 5 doors, blinds and venitian shutters. The building was intended to be converted into a dwelling in the event of its not being used as a cocoonery. Two rows of shelves, the whole length of the building, were put up, each shelf one foot above the other, so that I had large aisles between the rows of shelves and around them, affording ample room for feeding the worms and changing the hurdles. My hurdles are three by four feet, made with cotton twine, not knit, but crossed as a bed-cord. I supposed I had accommodations for feeding 2 or 300,000 worms hatched in succession. I accordingly procured two ounces mammoth white eggs, from Mr. Stone, of Burlington, which were understood to come from Germantown Pa., and several ounces of sulphur colored, from Mr. Comstock, of Hartford. These were all put in glass jars, and placed in the ice-house about the 1st of April. The 15th of June, the mammoth white were taken out and exposed for hatching, and in a few days, about 5250 of them hatched, which was all I obtained from the two ounces. I then exposed those I obtained from Hartford, not one of which hatched. Disappointed in my eggs, I called on Mr. A. M. Jerome, of Princeton, who supplied me with a paper of eggs which were in the process of hatching. These I brought home on the 26th of June, and about 25,000 of them hatched. I had then altogether about 30,250 worms. I placed them all on the shelves in the second story; about 12,000 on one side of the room, and the balance on the other side. I fed the whole on the multicaulis, grown from roots and cuttings planted this spring. During the whole time of feeding, the temperature ranged very high, being several days as high as 93 degrees Fahrenheit, and seldom less than 72 degrees.

When I commenced, all the knowledge I had on the whole subject was "book knowledge." I had never seen a cocoonery, and never but once had seen worms feeding. My colored man, who had never seen worms, gathered the leaves and fed the worms until within about two weeks of winding, when I employed an aged man to assist him. Having some leisure, I spent considerable time in the cocoonery, determined to watch the feeding with care. A premium of $100 having been offered by the Monmouth Silk Manufacturing Company, to the person who would raise the greatest number of pounds of cocoons from the sixteenth of an acre, I measured the above quantity of land, and planted it with roots set upright, the rows eighteen inches apart, and the trees eight inches apart in the rows. The 12,000 worms above alluded to, I fed on the premium trees. The drought continuing so severe, and fearing the leaves on the premium trees would fail, on the 19th of July I took off about 5000, for which I borrowed leaves to carry them through. From this time it required 143 pounds of leaves. In about twenty-six days the mammoth white began to rise, and in about 31 days all, or nearly all, had risen. On the 28th day a few of the sulphur began to wind, and by the 35th day, all had wound. As a general rule we fed four times a day, never at night. After the second week we changed the hurdles every two or three days; the room was well ventilated, and always sweet and clean. Although good attention was given to all the worms, yet a little more attention was given by myself to the premium worms. They were fed just as often as they consumed the leaves previously given, and the difference in the size of the cocoons was obvious, the premium cocoons being very perceptibly the largest and most firm. The whole number of pounds of cocoons from the worms fed as above, was 86 lbs. 9 oz.; the whole number of pounds fed on the premium trees was 38, or if an allowance is made for borrowed leaves, allowing 21 pounds of leaves to a pound of cocoons, the number fed on premium trees would be 31 pounds, 14 oz. Of the mammoth white it required 350 cocoons to make a pound; of the premium sulphur cocoons 290 to 300; 192 of the largest, after the floss was taken off, made a pound; of the sulphur colored cocoons, not premium, it required about 325 to make a pound. The worms were vigorous and healthy during the whole time of feeding, I I think remarkably so; indeed I do not know that I lost a single worm by disease. Being a healthy crop, I saved most of my cocoons for eggs, and I have about four pounds of the finest eggs I have ever seen. I stifled, probably, 25 lbs. of cocoons in order to make a specimen of sewing silk. August 4th I obtained a small paper of two crop eggs from Wm. Imlay, Esq., of Allentown; only 300 or 400 of them hatched, which I fed on my premium trees. These were also healthy and vigorous, but they did not wind under thirty days, and the cocoons were small. Owing to the impossibility of procuring eggs to hatch in successive crops, I have only raised 31 lbs. 11 oz. from my 1-16th of an acre, though my trees are smaller than yours in Burlington. This, I believe, is not more than one-half the amount I could have fed if I had been able to procure eggs and hatch them as wanted. The trees do not appear now to have lost any of their foliage. Enough has been done, however, to show that raising silk is profitable even the first year, in the hands of the most inexperienced. I hope you will write an article on this subject, and from what *has* been done, show what *can* be done. From my experience, I am perfectly satisfied there is no mystery or difficulty in feeding the silk-worm. If the eggs are from a healthy crop, and if the worms are kept clean and well fed, success is certain, and from the acknowledged enterprise of our people, I am perfectly satisfied the silk business will succeed, and at no distant period will become a source of vast national and individual wealth. May your valuable publication aid, as I have no doubt it will, in hastening this, by inducing our intelligent farmers and others to engage in the business.

R. V. M'LEAN.

Freehold, N. J., Sept. 20, 1838.

CURIOUS EXTRACTS FROM THE ANCIENT LAWS OF VIRGINIA.

In a former part of this work, there were presented many passages of history, and especially extracts from the older historians, in relation to the general policy and economy, and agriculture, and illustrative of the peculiar habits and condition of the early settlers and inhabitants of the colony of Virginia.* It is proposed here to offer extracts, equally curious and interesting, from the old laws of the colony, and spreading over a greater variety of subjects than was permitted by the purpose of the article referred to above. Though all the extracts which will now be offered are taken from a single work, 'Hening's Statutes at Large,' which is accessible to every one, yet because it is a *law book*, and a voluminous one, its contents are scarcely known to general readers, and it is almost sealed to all others except the members of the legal profession. For this reason, whatever is curious and interesting in these old statutes, will also have, to most readers of the Farmers' Register, all the freshness and interest of novelty.

The following introductory remarks and statements of the compiler of the statutes, will best serve as the beginning of these extracts:

"In June, 1619, the first assembly ever held in Virginia, was convened by sir George Yeardley, then Governor, and met at James Town; which was at that time, and for many years afterwards, called "James Citty." Some account of the acts passed at this session, (taken from the Ancient Records relating to Virginia,) is given in a note prefixed to the acts of 1623–4; being those of the earliest period now extant.

---

* See pp. 754 to 760, vol. III., Farmers' Register

"In May 1620, we are told by historians, that another assembly was held in Virginia. *Beverley*, indeed, makes it the *first* legislature under the colonial government. But of the acts of this assembly there is no mention in the proceedings of the London Company; a circumstance which renders it extremely doubtful whether such an assembly was, in fact, ever held."—Vol. I. p. 119.

But this first legislation of the colonists seems never to have been formally considered and ratified by the London Company, the then proprietary government of the colony, and therefore the enactments of this earliest session, whatever they may have been, were of no authority; and it is therefore, probably, that no record of them remains. Hening says—

"The acts passed at the general assembly in 1619, were probably a crude, indigested mass, which never received the sanction of the treasurer and company for Virginia, in England; without whose approbation, *in a great and general court*, they could not have the force of laws."—p. 122.

The first actual legislation, then, occurred in the next session, which was in 1621, and when fifteen years had passed since the first arrival of the English settlers. Of this, the only account is in the following general statement, given in the words of the compiler. This extract presents the curious fact, that a large and prominent portion of the first actual legislation of Virginia, (as well as much of later date,) was devoted to the encouragement of the growth of silk—a culture which, after lying dormant for nearly two centuries, has now suddenly become one of the most engrossing interest throughout this country, and which now promises to be revived, and for the first time to be extensively and successfully prosecuted.

"In November and December 1621, another assembly was held: an event not mentioned by Stith, or any of our early historians. The acts of this session are very briefly noticed in the minutes of the London Company; and relate entirely to the introduction and culture of such staple commodities as the company in England recommended; particularly the article of silk, which seems to have engrossed nearly the whole attention of the legislature. Two acts, the one prescribing regulations for planting mulberry trees, the other directing, that in clearing land, no mulberry trees shall be destroyed, are first mentioned. The remaining acts of this session contain little more than an enumeration of the wants of the colony."—p. 119.

There was lately republished in one of the newspapers, and which has been thence copied into many others, "*an act, for mulberry trees*," passed in 1661, which was presented as the oldest legislation on the subject. And, subsequently, there appeared in another print, a correction of that opinion, in extracts from the earlier acts of 1656 and of 1657. These extracts will be given here, in their order of time. It is enough here to show, that silk-culture was a subject of legislative interest and action, thirty-five years before the earliest of these enactments, and forty years in advance of the other.

The next extracts will be from the "Laws and Orders concluded on by the General Assembly, March 5th, 1623-4." In every extract the spelling and punctuation of the original, (as given in the 'Statutes at Large,') will be preserved.

"For the encouragement of men to plant store of corne, the prise shall not be stinted, but it shall be free for every man to sell it as deere as he can.

"That there shall be in every parish a publick garnary unto which there shall be contributed for every planter exceeding the adge of 18 years alive at the crop after he hath been heere a year a bushel of corne, the which shall be disposed for the publique uses of every parish by the major part of the freemen, the remainder yearly to be taken out by the owners at St. Tho's his day and the new bushell to be putt in the roome.

"That three sufficient men of every parish shall be sworne to see that every man shall plant and tende sufficient of corne for his family. Those men that have neglected so to do are to be by the said three men presented to be censured by the governor and counsell.

"That all trade for corne with the salvages as well publick as private after June next shall be prohibited."

"That every freeman shall fence in a quarter of an acre of ground before Whitsuntide next to make a garden for planting of vines, herbs, roots, &c. subpœna ten pounds of tobacco a man, but that no man for his own family shall be tyed to fence above an acre of land and that whosoever hath fenced a garden and of the land shall be paid for it by the owner of the soyle; they shall also plant Mulberry trees."—p. 125.

"That the proclamation for the rates of commodities be still in force and that there be some men in every plantation to censure the tobacco."—p. 126.

Our ancestors were totally without light on the free-trade doctrine of modern political economy, and had little faith in self-interest serving as the best guide to direct the pursuits of industry. The statute book is full of regulations, like some of the foregoing, which were designed to encourage and compel the raising or keeping of certain products, and restraining or forbidding others.

The following orders of the same session, exhibit the then state of insecurity and peril of every settler. They were enacted in consequence of the recent massacre of many of the colonists by the Indians, in 1622, which was so near being as complete as was its design.

"That every dwelling house shall be pallizaded in for defence against the Indians.

"That no man go or send abroad without a sufficient partie will armed.

"That men go not to worke in the ground without their arms (and a centinell upon them.)

"That the inhabitants go not aboard ships or upon any other occasions in such numbers, as thereby to weaken and endanger the plantations.

"That the commander of every plantation take care that there be sufficient of powder and ammunition within the plantation under his command and their pieces fixt and their arms compleate.

"That there be dew watch kept by night.

"That no commander of any plantation do either himselfe or suffer others to spend powder unnecessarily in drinking or entertainments, &c."

"That such persons of quality as shall be founde delinquent in their duties being not fitt to undergoe corporal punishment may notwithstanding be ymprisoned at the discretione of the commander & for greater offences to be subject to a ffine inflicted by the monthlie court, so that it exceed not the value aforesaid."—p. 127.

Among the acts of October, 1629, first appears the policy, which was so long approved, of limiting the extent of the cultivation of tobacco, for the purpose of enhancing its price, and which was so often attempted to be enforced by legislation, and with so little success.

"It *was put to the question* whether for this yeare there should be an ordinance made and established for the stinting of the planting of tobacco. To this the opinion of the most voices was, that noe persons workeing the ground, which are all to be thithable, should plant above 3000 plants uppon an head.

"An exception is made where the familie consisteth of children and woemen which doe not worke in the ground, and they to plant not above 1000 plants per pol."—pp. 41-2.

The following are some of the proceedings of the governor and council, acting as a criminal court, in 1630:

"Dr. John Pott, late Governor, indicted, arraigned and found guilty of stealing cattle, 13 jurors 3 whereof councillors. This day wholly spent in pleading; next day, in unnecessary disputation: Pott endeavoring to prove Mr. Kingsmell (one of the witnesses against him) an hypocrite, by a story of Gusman of Alfrach the rogue. In regard of his quality and practice, judgment respited till the king's pleasure known; and all the councel became his security."—p. 145.

"Upon the presentment of the church-wardens of Stanley Hundred for suspicion of incontinency betweene Henry Kinge and the wife of John Jackson, they lyinge together in her husband's absence; it is thought fitt that the sayd Kinge shall remove his habitation from her, and not to use or frequent her company until her husband's retorne."—p. 145.

"Hugh Davis to be soundly whipped, before an assembly of Negroes and others, for abusing himself to the dishonor of God and shame of Christians, by defiling his body in lying with a negro;* which fault he is to acknowledge next Sabbath day."—p. 146.

The three following acts, which are copied entire, throw light on the policy and economy of the government. The legislative encouragement or enforcing of corn culture was as much the usage as restraints upon tobacco culture. Tobacco was then, and for a long time afterwards, the legal currency of the country; and the bringing bad tobacco into market and circulation, was therefore something like debasing the coin of the country. This induced the burning of the article, as counterfeit, as well as to punish the owner for the offence. This penalty lasted much longer than its causes. Within the last thirty-five years, tobacco, condemned by the inspectors, was still burnt by law, instead of being permitted to be converted to manure, for which purpose it would have been valuable.

"For the better furtherance and advancement of staple commodities, and more especially that of potashes and saltpeeter, *it is thought fitt*, that every master of a ffamily within the severall plantations of this colony shall use their best endeavours to preserve and keepe in dry and tight houses or casks all those ashes that proceede and bee made by the wood that is burned in clearing their grounds, that they may be ready at all tymes to be delivered to those that shall require the same to make experiment thereof. And that every master of a ffamily shall have a speciall care, after a notice thereof given, to preserve and keepe all their urine which shall be made in their severall plantations, to be disposed and bestowed as by a note in writing they shall receave directions the benefitt whereof shall the first yeare shall redounde to those that shall make the experiment. And the next yeare it shall bee lawfull for every planter to make the best benefitt hee can thereof to his own use. And for other staple commodities, as iron, salt, vines, &c. the whole assembly are willing and readie to yielde their best assistance in setting and raysing them, or any of them when they shall see any incouragement thereunto by such as shall bee men of experience and skill to perfecte such workes."—p. 151.

"To prevent the want of corne which oftentymes doth happen to this colony by reason of the neglect of planting sufficient quantities thereof for their necessarie provisions, *It is ordered*, that two acres of corne or neere thereabouts bee planted for every head that worketh in the grounde, and the same to bee sufficiently tended weeded and preserved from birdes, hoggs, cattell and other inconveniences. And if any planter shall be found delinquent therein hee shall forfeite all his tobaccoe which hee made of his cropp that yeare, the one halfe, to the informer, the other to bee imployed to publique uses for the good of the country."—p. 152.

"For the improving the planting of tobaccoe the neglect thereof in the curing hath caused the same to bee of base price and small esteeme to the discredit and disadvantage of the whole colony in generall, for the preventing and avoyding whereof, *It is thought fitt and accordingly ordered*, That noe person whatsoever shall plant or tende above two thousand plants of tobaccoe for every heade within his family including woemen and children. And to the intent that noe tobaccoe of bad condition may be transported out of this country, *It is further ordered*, That if any man hereafter shall make any bad, or ill conditioned tobaccoe and offer to pay away the same to any person or persons, eyther for debts, marchandize or any other

* Negroes were first introduced in Virginia, from a Dutch ship, in the year 1620. See Beverley, pa. 51. Burk's Hist. vol. i. p. 211.

commodities, it shall be lawfull for the commander of every plantation with two or three discreete men of the said plantation uppon view thereof to burne the same. And the partie that shall bee found delinquent in any particle of this order shall bee hereby barred from planting any tobaccoe until hee bee re-admitted by a General Assembly."—p. 152.

"For the better increase and multiplying of cattell in this colony, it is thought fitt that all the female increase of neate cattell bee with all care and diligence preserved and kepte. And that noe female kinde of cattell bee killed unlesse they bee such as are eyther past breedinge, or are likely to dye by some infirmity. And if any person or persons shall doe contrary to this acte they shall undergo such censure as the Governor and Councell shall thinke fitt to impose upon them." p. 153.

"Mynisters shall not give themselves to excesse in drinkinge, or riott, spendinge theire tyme idellye by day or night, playinge at dice, cards, or any other unlawfull game; but at all tymes convenient they shall heare or reade somewhat of the holy scriptures, or shall occupie themselves with some other honest study or exercise, alwayes doinge the thinges which shall apperteyne to honesty, and endeavour to profitt the church of God, alwayes haveinge in mynd that they ought to excell all others in puritie of life, and should be examples to the people to live well and christianlie." p. 158.

"Uppon a remonstrance preferr'd to the assembly, complayninge that the ffrenchmen who were, about ten yeares since, transported into this country for the plantinge and dressinge of vynes, and to instruct others in the same, have willinglie concealed the skill, and not only neglected to plant any vynes themselves, but have also spoyled and ruinated that vyniard, which was, with great cost, planted by the charge of the late company and theire officers here; and yet notwithstandinge have receaved all favour and encouragement thereunto, which hath disheartened the inhabitants here, *It is therefore ordered* that the sayd ffrenchmen, togeather with theire families, be restrayned and prohibited from plantinge tobacco, uppon penaltie to forfeit theire leases, and imprisonment untill they will depart out of this colony."—p. 161.

"Be *it also further ordered*, That no planter or mayster of a famylie shall plante or cause to be planted above two thousand plants per pol, and that those that shall not plante or be otherwise imployed shall not transferr or make over theire right of plantinge unto any other; and to prevent any greater quantities, every planter or mayster of a famylie plantinge a cropp of tobacco, more or lesse, shall be tyed to procure one of his neighbours or some sufficient man to come and nomber his or theire plants of tobacco, who will uppon his oath declare and testifie unto the commander of that place, before the tenth day of July, that he hath counted and nombred the sayd plants, and shall say in his conscience the just and true nomber of them, which thinge yf the sayd planter or mayster of a famylie shall neglect, or that the nomber of the plants is found to exceede the proportion of 2000 per pol, then the commander is hereby to present it to the next mounthlie cort, and the commissioners thereof shall give present order to have all that whole cropp of tobacco cutt downe under panye of imprisonment and censure of the governor and counsell and grand assembly yf they neglect the execution thereof. Also uppon the neglect of the commander, he shall be censured in like manner."—p. 164.

"It *is likewise enacted*, That no person shall tend, or cause to be tended, above 14 leaves, nor gather or cause to be gathered above 9 leaves uppon a plant of tobacco; and the several commanders shall hereby have power to examine the truth thereof; and yf any offend, to punish the servants by whippinge, and to bind over the mayster unto the next quarter cort at James Citty to be censured by the governor and counsell."—p. 164.

"It *is ordered and ordeyned*, That no person shall tend, or cause to be tended any slipps of old stalkes of tobacco, or any of the second cropps, uppon the forfeiture of the whole cropp, whereof halfe to be to the informer, and halfe to publique uses as aforesayd."—p. 164.

"It *is likewise ordered*, That every man workinge in the ground, shall plant, or cause to be planted, and sufficientlie tended, this yeare, at the least two acres of corne per pol, uppon penaltie of forfeiture of their whole cropp of tobacco, yf uppon vewe thereof they shall be found deficient." p. 166.

The following act, passed in the session of 1631-2, shows the continued state of danger and alarm:

"All men that are fittinge to beare armes, shall bringe their pieces to the church uppon payne of every offence, yf the mayster allow not thereof to pay 2 lb of tobacco, to be disposed by the churchwardens, who shall levy it by distress, and the servants to be punished."—p. 174.

In 1632, an unusually long and particularly penal act was passed for improving the quality of tobacco. It required that no tobacco should be bartered for other commodities at a lower rate than sixpence the pound; that no planter or master of a family should plant more than 2000 plants "per pol;" that no more than 14 leaves on each plant should be tended, nor more than nine leaves gathered from each plant of tobacco; and that no second crop should be made from the suckers, (or "seconds") growing after the cutting off the first crop.

Another act of the same session compelled the planting of vines; but it does not appear that this, or any other of the means of encouragement used, had any important effect in causing wine to be made.

"It *is provided and ordered*, That all workers upon corne and tobacco shall this ensuinge springe before the first day of March next ensuinge, plant, or cause to be planted 20 vyne plants per pol uppon penaltie to forfeite one barrell of corne for every one that shall make default one halfe to be to him which shall make information thereof and the other halfe to publique uses. And the commissioners for the mounthlie corts shall have full power to heare and determine this matter and to see that the sayd vynes bee weeded, tended, and well preserved."—p. 192.

This act was repealed in the ensuing year, by the following, which directs other cultures:

"It *is ordered*, That the 25th act made the 4th day of September 1632 be repealed and voyd. And that every planter as soone as he may, provide seede of flaxe and hempe shall sow the same."—p. 218.

The following short act, is the origin of the present abominable law of inclosures, which operates now as a heavier tax upon agriculture, and a greater absorber of its profits, and obstacle to its improvement, than all the other burdens imposed in taxes, or otherwise:

"Every man shall enclose his ground with sufficient fences or else to plant, uppon theire owne perill."—p. 199.

Another act of the same session, 1632, forbids the killing of wild hogs, on the lands of others, and offers a reward for killing wolves. The settlements, then, were all in the lower tide-water counties, and the falls of the rivers were as yet in "back-woods." It seems that at least one act of protection had been effective—that for increasing the number of cattle; whereupon the assembly determined not only to continue the prohibition to kill female cattle, but also to prohibit their being sent abroad to the other colonies, for sale:

"Whereas it doth appeare that the late preservation of female neate catle within this colony hath much encreased the nomber of them and inritcht this colony, and the continewance thereof yet for a tyme will much encrease the nomber of them further; *It is ordered*, That no cowes, heifers, or female catle be transported to any other parts out of the government of this colony now established, upon the forfeiture of the catle soe transported, or the true value of them, the one halfe of which forfeiture shall be to the informer, and the other halfe to publique uses. And this act to continew in force untill the next Generall Assembly."—pp. 218-19.

The limitations on producing tobacco being still found insufficient to increase the price, the following additional act was passed, in 1639, by which *half of the good tobacco*, as well as all the bad, was ordered to be burnt.

"Tobacco by reason of excessive quantities made being soe low that the planters could not subsist by it or be inabled to raise more staple comodities or pay their debts, *Enacted*, that the tobacco of that year be viewed by sworn viewers and the rotten and unmerchantable and half the good to be burned. So the whole quantitie made would come to 1,500000 without stripping and smoothing: and next 2 years 170 lb. tobacco per poll stript and smoothed was to be made which would make in the whole about 1,300000 lb. and all creditors were to take 40 lb. for a hundred." pp. 224-5.

But tobacco being the current money in which all obligations were made, and debts paid, it followed that the effecting the much desired object of raising the price, would also as much increase the actual amount of every existing debt. The next thing necessary was to cut down every debt to what the assembly deemed a proper amount, which was provided for in the several following acts of the same session:

"Noe man to be obliged to perform above half his covenants about freighting tobacco in 1639." p. 225.

Debtors were "not to pay above two-thirds of their debts during the stint," or prohibition of cultivation of tobacco.—p. 226.

An act to plant orchards, made in 1636, (of which there is no other notice,) was reversed in 1639-40.

The following provision, made the same year, was a departure from the general principle of the fence law, but which unfortunately was not persevered in:

"Hoggs to be confined in pens by night and to have keepers by day or owner to satisfie all damages done by them."—p. 228.

In 1642, the owners of hogs were restored to the rights which they continue to retain to this day:

"Be it also enacted & confirmed, That ev'rie planter shall make a sufficient fence about his cleared ground, And if he be deficient therein, what trespass or damage he shall susteyne by hoggs, goats or cattle whatsoever shall be to his own losse and detriment."—p. 244.

The following enactment was made to guard against a singular kind of waste—the burning of houses, when left vacant, merely to get the nails:

"And it is further enacted by the authoritie aforesaid, That it shall not bee lawfull for any person so deserting his plantation as aforesaid to burne any necessary houseing that are scituated therevpon, but shall receive so many nailes as may be computed by 2 indifferent men were expended about the building thereof for full satisfaction, reservinge to the King all such rent as did accrew by vertue of the former grants or planting of the same from the expiration of the first seaven years."—p. 291.

"To rectifie the great abuse of millers, Be it enacted that no person or persons shall for the grinding any grayne that shall be brought vnto them take above the sixth part thereof for toll." p. 301.

The following singular enactment doubtless was expected to remedy all complaints against the gentlemen of the legal profession, as it aimed to destroy all the attorneys at one blow, by forbidding their receiving any fees for their services. It is to be presumed, from the results, that the prohibition did not work well.

"Whereas many troublesom suits are multiplied by the vnskillfullness and coveteousness of attorneys, who have more intended their own profit and their inordinate lucre than the good and benefit of their clients: Be it therefore enacted, That all mercenary attorneys be wholly expelled from such office, except such suits as they have already vndertaken, and are now depending, and in case any person or persons shall offend contrary to this act to be fined at the discretion of the court." p. 302.

(To be continued.)

UNROTTED LEAVES AS MANURE. LATE SOWN WHEAT.

To the Editor of the Farmer's Register.

On reading your article, in the November number of the Register, on the subject of the use of leaves as a manure, I am induced to offer you the following experiments which I have made with them, as you have solicited communications from the patrons of the Register. Early in the spring of 1837, I covered about 15 acres of highland, with leaves taken from land cleared the previous winter. The land on which I put the leaves was very rolling, and about sixty feet above the level of the flat land on the river. It was very much overrun with blue grass, and required a cleansing crop. The leaves were spread very thickly, and then plastered, at the supposed rate of a bushel and a-half to the acre. The land was then ploughed deeply with a two-horse plough, and was soon after planted in corn, and cultivated altogether with the coulter and hoe. At first it was backward in growing off; but, after it started, it grew rapidly, and withstood the drought of the summer, and continued green longer than my low-ground crop. I did not ascertain the difference between the product of this piece of land and other highland corn that I had on richer and better land; but the result was decidedly in favor of that to which the leaves were applied.

In the fall of 1837, I covered with leaves, quite thickly, a piece of highland of nearly twenty acres, and sowed plaster on two-thirds of the lot, not having enough to sow it all. The leaves were ploughed in, early in January, and before planting corn the land was well harrowed. The cultivation of the crop as before was altogether with the coulter and hoe. It withstood the extreme drought of the past summer better than my low-ground corn; and the fodder continued longer green on it, and the yield, though not ascertained by measurement, was a very good one.

I am quite a novice in farming; but the result of my experience (though differing from yours) is, that leaves ploughed in, the earlier in the fall the better, are a valuable manure for corn. They keep the roots moist, and yield nourishment to the plant, and in a dry season have not the injurious effect, that farm-pen and stable manures have, of making the crop so liable to burn.

In the fall of 1836 I was stopped in sowing wheat by rain on the 13th November, and though I had only a few days' ploughing, the weather continued so unfavorable that I did not finish sowing until the 14th December. The wheat sowed between the 1st and 13th November had come up before I finished sowing; and that sowed last did not come up until about the middle of February. It then came up very well, and was nearly though not quite so thick as the rest of my field, all being on low-grounds. The weather just before harvest was so wet as to cause rust in a considerable part of my crop. I found on examination that the wheat I had sown between the 1st and 13th November was very much rusted, and that sown on the 14th December was entirely free from it; and the latter yielded as well as the rest of my low-ground crop. This, though it is at war with the speculations of some of the correspondents of the Register, is no guessing matter, as I have taken it from a memorandum made at the time. The kind of wheat sowed was purple straw and red bearded, which had accidentally got mixed, and they are both late kinds. That sowed in December had only an equal chance with this humbug of spring wheat, and I am quite sure the yield was fully equal to any spring wheat I have seen. Can you, Mr. Editor, or any of your correspondents, explain why the wheat sown in November should have the rust, whilst that sown one month later did not, when every thing was in favor of the first? It was sown next the river, where the land is light and loamy, and was put in in fine order; whereas that sown in December was on stiff land, inclined to be wet, and, moreover, was ploughed before the land was in good order. The sowing of wheat this fall is unusually late, and the fact above stated may not be uninteresting to your readers. A PLANTER.

James River, November 10th, 1838.

SINGULAR AND FATAL DISEASE OF HORSES.

To the Editor of the Farmers' Register.

Pasquotank County, N. C. Oct. 25th, 1838.

I have lost the greater part of my horses in about 15 days. The 1st of October I discovered two were sick, and they continued to sicken and die until I had lost seven. They were sick from one to ten days. The symptoms were at first, when moving, a rattling in the throat, and unwillingness to move quick; a discharge from the nostrils of a thick ropy phlegm, and, as the disease advanced, it changed to matter, and was offensive, except one; they did not appear to be in violent pain; they had a disposition to eat and drink, but were not able to swallow—had not the least swelling about the throat—eyes not at all affected, although at times a high fever. The second horse that was taken sick, after living three days, and being unable to stand, I had killed for the purpose of opening. I was very particular in examining; the lungs were very much enlarged, and discolored; the same substance that was discharged from the nose was mingled with the lungs. There was nothing in the stomach but water; the rest of the intestines were filled with such food as I should have expected to have found in a horse in health, apparently not affected in the least. No obstruction from the throat to the stomach. The next was opened by a physician. His heart was very much enlarged, the lungs in the same situation as the first. That horse lived but 15 hours after I discovered him to be sick. The day before his death he eat hearty and appeared to be well. The next I opened lived 10 days; his lungs were diseased more than the others, and the discharge from the nostrils very offensive. His heart was not affected. The 4th was in the same situation. As soon as I discovered the disease was a fatal one, I separated my horses, and moved them a quarter of a mile from the house; but it did not have the desired effect. I have two horses that I think will recover. All of my horses were affected but one that had the staggers a few weeks previous, and 3 colts. They were fed with cut oats and fodder, and when they were used they had corn. They were all fed in one stable except the colts, and all ran in the same pasture during the day, but my saddle horse; he remained in the stable, except when in use. He was the last attacked, and had the disease light, I think in consequence of his being bled very freely before and after he was taken. One of my neighbors had a mare and colt, that remained in my pasture all the summer and fall, which were not affected. The food that was given the horses had not been damaged, and was sweet and sound; they were watered in Pasquotank River. The stables were littered with corn-stalks and wheat-straw—were dry, and had no unpleasant smell that I was aware of. The horses had salt once or twice a week. Feeling very anxious to account for the cause of the affection, and knowing no better source for information than your Register, I have applied to you, thinking that you or some of your subscribers may account satisfactorily for it.

THOMAS HARVEY.

A SUGGESTION FOR IMPROVING CHIMNEYS.

To the Editor of the Farmers' Register.

Surry Court-house, Va. Nov. 7th, 1838.

A plan has suggested itself to me for the construction, as I think, of an improved chimney. It is simply this: In a common chimney, from about the middle of the hearth, and just under the spot designed for the fire, let there descend a channel or opening, in an inclined direction towards the back, so as to pass out on the back of the chimney the thickness of six or eight bricks below the level of the hearth. The size and form of this feeder, as I would call it, can be varied according to choice. I should prefer having this, or at least the inner part, long and narrow, say one half the width of the fire-place, and to stretch across, or in the direction of the fuel laid on, so as to keep up a current of fresh air to the whole at once. The outer part of this opening may be of a different form; round, square, or in any shape sufficiently large to admit of the passage of the ashes, &c. outward, and a current of air inward.

The advantages to be derived from this plan, are, I think, several; and one of which is of particular importance. This is derived from the continual current of atmospheric air streaming through this channel, and by this means affording to the combustible matter, from an inexhaustible source, an abundant supply of oxygen gas, the necessary and indispensable agent of all combustions; thus feeding the flame from without, (instead of from within the room, to the great detriment of the air for animal respiration,) which is a matter deserving much more attention than is generally given to it. Close confined rooms, with fires burning in them for a length of time, the burning of candles, lamps, &c., and the breathing of persons in the same room, have a poisonous effect upon the lungs of animals. This, no doubt, is the source of many pulmonary and fatal diseases. We should ever keep in mind, that combustion and animal respiration are supported from the same source; and to be regardless of this, is to be regardless of our health, and consequently our happiness. But this is not the only advantage to be derived from this plan. It would supersede the disagreeable and dangerous job of taking up and moving the ashes from the hearth, which is so frequently necessary. These, as they were formed, would be saved or separated from the coarser unburnt coal by small rods of iron, or a coarse wire grate, let into the hearth over the mouth of the feeder, and conducted away through the opening into whatever may be prepared for their reception. Some precaution would be necessary in keeping the fresh ashes from the wind during dry weather.

D. S.

THE NORFOLK COMMERCIAL CONVENTION.

The second commercial convention of Virginia has been recently held; and the manner of its procedure, and conclusions reached, are, in the general, such as to promise well for the improvement and commercial independence of the state. This convention, more fortunate than its predecessor, kept clear of party questions, and even of the *suspicion* or imputation of the influence of party objects. This was as it should be; and Virginians and Carolinians, of different political parties, and of various interests, met here, with the one common object which all zealously and earnestly urged—that of sustaining the commercial independence and general good of the states which they represented.

The most important and practical results of the deliberations of the body, will be presented in the reports of committees considered and deliberately approved, and in the resolutions founded thereon, and adopted by the convention. These were, the report of the general committee on the causes of, and remedies for, the decline of our direct trade with Europe—the report of the committee on agriculture—the report of the committee on manufactures—and the report of the committee on banking—together with the resolutions on each, as amended and passed by the convention; and also the single general resolution adopted on the policy of the commonwealth in regard to internal improvements, by the construction of canals, railways, &c. This subject, important as it is in itself, was here but subsidiary to the main object of the convention, and should by no means have been permitted to occupy the foremost ground in debate, and the greater part of the whole time of the session. But, unluckily, some thought an opposite course expedient; and which was more like to subserve other interests than the great cause of internal improvement. The result of all the long and earnest debate on this subject was the adoption of the following resolution, (as amended by the convention,) the remainder of the series being indirectly rejected, by a close test vote to lay on the table, to remain there.

"Resolved, in the opinion of this convention, that a liberal system of internal improvement is one of the best foundations for a direct import trade, and the surest means of effecting it."

It would be very incorrect to infer that those who opposed the rejected resolutions were opposed to a proper and liberal system of internal improvement. It is believed, that if there were any members so opposed, they were very few in number. But the objections entertained were to the wide scope and ultra character of the resolutions—the descending to details and propositions of very doubtful character, at least, and which, even if judicious, and proper to be approved, belonged only to a body having legislative power—and in addition to these objections, that of spending the limited time of the convention in debate, which would certainly be fruitless and profitless to the public good, upon an inferior question, which it was impossible to fully consider, or harmoniously to agree upon.

But, notwithstanding the waste of time on these rejected propositions, there was great deliberation and attention given to the several reports and resolutions which have been referred to. Of course, a body which can enact nothing, is not required to enter upon details, nor to scrutinize them very closely. But the main questions on the business of the convention, in their general purport and bearing, were decided upon carefully and deliberately. There never was a similar body more attentive, more laborious, more guarded against surprise, or the insecurity caused by indolence and carelessness, until all that was considered the business of the convention had been decided upon. After the last expected of these subjects had been voted upon, (which was the report and resolution of the committee on manufactures,) and when the necessary hour of final adjournment was close at hand, and nothing more was counted on but the usual resolutions of mere form and routine, many of the members retired from the hall, and most of those who remained either were unable to hear the resolutions offered, or did not attend to them. So it was, that in the conclusion of the last day's session, there were resolutions offered and passed by a very few voting either for or against, through inattention or by surprise, which certainly would not have passed in any previous time of the session. It is as needless to specify the subjects of such action, as it is unpleasant to have to make any such statement.

The direct results of this meeting will be of far less value than the indirect. Much good is done merely by the meeting of fellow-citizens from distant localities, having (as supposed at least) rival and conflicting interests, and who have heretofore permitted themselves, in a greater or less degree, to be influenced by sectional prejudices, and commercial jealousy. Better feelings have been already produced, and they are cherished by all parties; and we are perfectly satisfied, that if these conventions are continued, even if no direct operation whatever should result, incalculable benefit will be effected, in removing narrow-minded jealousy and blind hostility, and producing instead those opposite feelings between every different locality and every different interest, which all true Virginians and southrons must desire. Under these impressions, we heartily approve of the two resolutions of the convention, by one of which they recommend another convention to be held next November, in Raleigh, for North Carolina and Virginia; and by another, recommend to those states to send some members to the commercial convention of the more southern states, which will be held in Charleston next May.

The convention agreed with unexpected unanimity in favor of the general recommendation of increased banking capital and banking facilities, as means necessary to enable our commerce and manufactures to have a chance for advantages equal to those of the northern cities. But the manner of increasing, and all details, (on which there would have been irreconcilable differences of opinion among some who voted together in the affirmative,) the convention wisely left to be settled by the legislative power. There are few reflecting persons who will not admit that Virginia and North Carolina have already lost much by not availing sufficiently of the advantages and benefits of banking upon correct principles, while they have suffered their full share of the evils and losses of the bad system which has prevailed. There were members of the convention who voted affirmatively on the general question of the expediency of increased banking facilities for Virginia, who are utterly opposed to the main features of the existing bank charters—and particularly to the partnership interest, and connexion, between the banks and the state, and to the virtual irresponsibility of the banks for all violations of their charters and other legal as well as moral obligations, which irresponsibility necessarily grows out of that connexion, by giving them a controlling influence over the legislature. We fully concurred in these views; and would wish that the trade and business of banking should be left as free from the prohibitions of law, and the monopoly privileges of the older institutions, as any other branch of trade; but *provided always and surely*, that all corporations and individuals who may pursue the trade of banking, shall be held as strictly responsible for the performance of all their obligations, as are those who are engaged in other trades. We care not to what extent banks may be put in operation in Virginia, (and without charge of bonus, or any other share of their profits on the part of the state, as monopoly-giver,) so long as proper care shall be used, (as is expressed in the report of the convention,) that "*provision be made against the abuse and perversion of their powers.*"

We proceed now to give the several reports above referred to, together with the resolutions of the convention, founded thereupon.

Report and resolutions on the causes of the decline of the direct foreign trade, and the means of remedy.

The committee who were instructed to consider and report upon the object of this convention, respectfully report, that they have carefully considered the important questions submitted by the convention for their examination. In the prosecution of their inquiries into the latent causes of our commercial decline, they have avoided all questions which involve subjects of party preference or political disagreement. Such discussions might not, indeed, be wholly irrelevant, but they believe that there is sufficient common ground upon which every friend of southern commerce may consistently stand, without touching subjects of party dissension, or trenching upon the lines, which divide the public sentiment at the present day. Your committee, therefore, without slurring over any inquiry, which they deemed essential to a correct understanding of the important questions confided to them, have confined their notice to those plain, simple and conceded truths, which only require to be stated to secure the assent of all.

Commerce is but the exchange of property, and however diversified and intricate some of its operations may seem, they are merely designed to facilitate such exchanges. The existence of trade between any two countries, is evidence that neither can sufficiently supply itself from its internal resources, with those things that may gratify the wants of its people. No nation would be guilty of the supererogation of sending abroad to obtain what it was already abundantly possessed of; as no individual would seek his supplies beyond the limits of its own domain, if he could always find there whatever might satisfy his real or his fancied wants.

The same necessity which impels a nation to seek abroad those things, which its own industry cannot supply, would prompt it to obtain what it wanted from the nearest and most convenient point; nor is it probable that its trade would ever be diverted from such a channel so long as its own products could be advantageously exchanged for those of such neighboring community. An individual residing in the town of Hampton, would scarcely submit to the delay and expense of obtaining from the city of Richmond any article that he could purchase upon as good terms in Norfolk Borough; and when he had effected his purchase in Norfolk, he would be still less disposed to bear the unnecessary cost of its transportation to Richmond before receiving it at his own home. In the case supposed, the interests of the purchaser would be as injuriously affected, where the expenses of this circuitous conveyance were paid by the seller, as they would be where he is himself immediately subjected to the increased cost; for, it is obvious that the seller, by undertaking to pay the charges of such an indirect transportation, would be unable to sell his goods at as low a price as he otherwise might be, exactly the amount which he is to pay for their conveyance.

Having shown that "a direct trade is the natural channel of communication between nations," the committee do not deem it necessary to enter into any argument to prove that the trade which supplies the people of Virginia with foreign goods, imported into the northern ports, is *not* a direct trade. To those who are at all acquainted with the geographical relations existing between us and those by whom this trade is conducted, such an argument would be a mere waste of time.

They proceed to consider the more important inquiry, whether any and what part of our consumption of foreign merchandise, is supplied by means of this indirect communication. Upon this point, information has been obtained of as precise a kind as the nature of the case will admit; and it places in a striking light the disadvantages to which this and the other southern states are subjected, from the present condition of their trade. Were there not the most indisputable evidence of the fact, it would scarcely be credited, that when the total imports of the United States amounted to $126,521,332, the imports of Virginia amounted only to the sum of $837,325; while of the total exports, estimated at $104,336,973, those of Virginia amounted to near five and a-half millions of dollars. Of the above amount of imports, those of New York alone exceeded $73,000,000, while the imports into North Carolina were less than one-fourth of a million. Those of Massachusetts amounted to $17,672,129, while South Carolina imported but to the value of $1,787,267. Those of Pennsylvania to $10,479,268, while Georgia received little more than $550,000, and Alabama less than $400,000.

In further illustration of this branch of the subject, the committee present the following extract from the able report submitted to the late convention at Richmond, by their committee, the statements and estimates of which, were based upon the latest official returns, and are believed to be entirely accurate. It will be seen that they are in close accordance with the statements presented above. "On examining the official returns it will be found that the exports from this state, on an average of the three last years, terminating on the 31st December last, amounted to $5,265,461, and the imports to $816,887, the former being to the latter, nearly as thirteen to two. For the same period, the average exports of all the staple states amounted to $72,107,039, and their imports $22,303,656, while the exports of the other states for the same period amounted but to $29,316,019, and their imports to $116,908,721, making the exports of the staple states compared to their imports as 7 to 2, while the exports of the other states are to their imports as 1 to 4."

The report, after adverting to the fact, that the official returns do not give the coasting trade, and that many of the exports from the northern states are products of the south, proceeds as follows. "From these results it appears that of the exports of this state nine-tenth part is direct and one-tenth circuitous through the ports of the other states—and assuming that her imports should be equal to her exports, only one-seventh part is direct and six-sevenths circuitous. Nor is that of the staple states generally in a much better condition. Taken in the aggregate, nine-tenths of their exports are direct, and one-tenth circuitous; while of their imports on the same assumption, only two parts are direct and seven circuitous, subject to all the expense and burthens incident to such intercourse.

Considering this subject upon the received principles of political economy, it would be a natural inference, that a diminution in the imports of any nation would be attended by, or, at least, would indicate a corresponding decrease of its exports; and yet, startling as the fact may seem, the reverse is true of the trade of the different sections of this country. The exports of the southern states have been steadily increasing, during the whole period that their imports have been dwindling to their present insignificance, while the enormous increase in the imports of the northern states, has been attended with so slight an improvement in the sum of their own products, exported to foreign countries, as to be scarcely worthy of mention. In the year 1830, the exports from the United States, of the products of agriculture, amounted to near $47,000,000, of which the articles of cotton, tobacco and rice alone, constituted more than four-fifths; and in the short space of four years, the exports of the products of agriculture had increased to upwards of $67,000,000, of which the exports of cotton alone exceeded in value the whole agricultural exports of 1830. On the other hand, the exports of manufacturers, which were chiefly the product of northern industry, amounted in the same year to only $6,-258,131, and in the year 1834 to but $6,648,393, showing a trifling increase of less than $400,000, while in the same period, the increase in the value of the agricultural exports, which were chiefly the products of the south, amounted to more than twenty millions of dollars.

If we confine our notice to the great staple of cotton, which is peculiarly the product of southern industry, the enormous increase in our exports will be placed in a yet more striking light. This article was not even cultivated in the United States until about the year 1790; but in ten years afterwards, the crop was estimated at 35 millions of pounds; in 1810 at 85 millions, in 1820, at 160 millions, in 1830, at 350 millions, and at the present day it may be fairly computed to exceed 500 millions of pounds. In the year 1830, after supplying the large domestic demand, the exports of cotton to foreign countries amounted to near 30 millions of dollars, and in the year 1834 to the astonishing sum of fifty millions.

Thus is exhibited the singular anomaly, of a country losing the command of its import trade, as it really improves in its capacity to control it. The extent of this decline, the committee now propose to consider. It is a well known fact, that before the establishment of the present government of the United States, the imports of Virginia largely exceeded those of any other State, being at one period nearly five times greater than those of New York, and even more than the aggregate of the whole New England States. The address of the second commercial convention at Augusta, quoting from a writer in the Richmond Whig, states the value of the imports of Virginia in 1769 at £851,-140 sterling—New England States 561,000—New York, 189,000—Pennsylvania, 400,000, and South Carolina, 555,000.

The committee deem it unnecessary to exhibit the successive stages of deterioration in the imports of Virginia, and the other southern states. Let it suffice, to invite attention to the contrast now presented, in the condition of our import trade, at the last named period, when its value was near five times greater than that of New York, and its present state of comparative nothingness, when it is ninety times less.

It is due to candor, and to the character of the southern people for energy and intelligence, to state that the decline of a considerable portion of our foreign import trade, may be accounted for in the fact, that we now derive from the northern states many of those articles that we formerly imported from abroad. At no very remote period, we were dependent upon Great Britain for even such wares and fabrics as are now often manufactured in our own households; and it not unfrequently happened that orders were sent abroad, for bricks and other materials for constructing our very dwellings. While we yet stood in the relation of colonies to Great Britain, the hard policy of the mother country repressed all our endeavors to establish manufactories, of even the simplest articles, and, in some cases, visited with severe penalties those who embarked in certain prohibited employments. It is known that this rigorous system of colonial oppression was a fruitful source of those dissensions, which resulted in the establishment of our national independence. That some idea may be formed of the extent of the importations into Virginia of those articles that are now chiefly produced by the domestic industry of the country, the committee present the following statements, compiled by a well known writer several years before the American revolution. "The people [of Virginia] may amount to about five hundred thousand, which may reasonably be supposed to bring no small advantage to their mother country—as from hence they are all supplied WITH ALL THE NECESSARIES OF LIFE, such as linen, silks, India goods, wine, and other foreign manufactures: and of our home ones, cloths, serges, stuffs, bays, hats, and all sorts of haberdashery ware, hoes, bills, axes, nails, adzes, and other iron tools, clothes ready made, knives, *biscuit flour*, stockings, shoes, caps for servants, *and indeed almost every thing that is made in England, to the amount of near 1,000,000l. sterling*, which is repaid mostly in tobacco, of which it is supposed by the nicest calculators, that near one hundred thousand hogsheads are, in time of peace, imported yearly, *employing between three and four hundred ships*, navigated by upwards of four thousand sailors." *Wyndham Beawes.*—From the details given by the same authority, of the trade of the New England States, it will be seen that they were themselves dependent upon the mother country, at that time, for those wares, which they now supply in considerable quantities to others. He says, "They take from hence *all kinds* of mercery goods, linen, stockings, shoes, sail cloth, cordage, haberdashery ware, and a vast many other things."

The loss of a portion of our foreign imports is thus sufficiently accounted for, in the substitution of a nearer and more convenient source of supply. Such a diversion of our trade is no proper subject of regret. On the contrary, it furnishes, both to the manufacturing and to the staple states, occasion for mutual rejoicing. It is, therefore, in no spirit of complaint, that we refer to it as one of the causes of the diminution of our foreign imports: but merely to show that it has not been overlooked by the committee, and that due allowance has been made for its operation, in producing the decline of our foreign trade. Did we receive from the northern states only such merchandise as is the product of their own industry, we should be constrained to admit that the evils which we complain of are unreal and shadowy; and that the decrease of our foreign imports was but the evidence of the superior advantages of the domestic trade. But when it is recollected that the large importations made into their ports, are designed to supply not merely their own consumption, but that of the southern people also, it can scarcely be contended, that the present condition of our commerce arises only from the cause alluded to.

As to the causes which have had the most powerful operation in producing the injurious results which the committee have noticed, much difference of opinion exists. The funding system, the Bank of the United States, the tariff, have been attacked and defended, in turn, by their respective opponents, and advocates, as the agents of mischief, or the fruitful source of good. Unfortunately, these measures (the last two, at least,) are too nearly connected with the party preferences of the present day, to receive that dispassionate examination which would be necessary to determine how far their agency had operated, for good or for evil, upon the interests of southern commerce. It is the less needful indeed to enter upon such an inquiry, as its successful result, however it might gratify an enlightened curiosity, could lead to few consequences of a practical nature. The bank no longer exists, and the protective policy is believed to have been abandoned. Whatever may have been their effects, they have now ceased to operate; or if they are still felt, they can be neither checked nor promoted, by a solution of the question, whether the decline of our foreign trade was in any wise attributable to them.

There is, however, one cause of this decline, which the committee cannot omit to notice, believing that a knowledge of its operation may be useful, in itself suggesting its appropriate remedy. They allude to the withdrawal of British capital invested in commerce in this and the other southern states, anterior to the revolution. The business of the colonies was conducted, for the most part, by the agents of British capitalists; and even the resident merchants were chiefly foreigners, whose means were supplied from the mother country. The effect of the revolution upon such a state of things, may be easily conceived. Most of the agents were recalled—many of the resident merchants, having no permanent attachment to the soil, and either feeling no sympathy with our grievances, or taking part against us, returned to their transatlantic homes, while the number of those that remained was gradually reduced by death and retirement from business. The withdrawal of so large a portion of our commercial capital, could not but exercise a prejudicial influence upon our foreign trade. It is true that the same result was experienced in the northern states; but, as will be presently seen, in a much less degree. The principal exports of the colonies had been supplied by us, and to us came the far greater portion of the articles that were necessary to purchase them. The merchandise that was thus sent to us being owned by British merchants, and transported in ships belonging to British capitalists, and for the most part manned by British seamen, there could be no motive in policy or reason, for sending them to any other ports than those where their freights could be most conveniently received or discharged.

It was necessary that the vacuum produced by this withdrawal should be supplied. In the competition that ensued for carrying on the trade, thus thrown open, the greater advantage would be secured by those whose condition better fitted them for conducting it. We were in some respects more illy prepared, than the northern States, for engrossing the profits of this trade. Anomalous as it may seem, our very wealth was, to this extent, a source of disadvantage. As has been already shown, the products of our soil were much larger in proportion to our population, than those of the northern states. The rewards of agricultural labor were, of course, richer with us than with them; as it is obvious that where a large production is to be divided among a small number, the average distributive share will be greater, than where the reverse is the case. It would follow that their labor would be diverted before ours from the cultivation of the soil to the pursuits of commerce and manufactures. *They* would be induced to embark in these new employments by the hope of any compensation greater than that which rewarded their agricultural industry; while *we* could not afford to abandon the pursuits of tillage for any recompense short of that which husbandry would yield.

Having thus a larger portion of their capital invested in the pursuits of commerce, they were enabled to compete with us successfully, for that trade which was properly our own. Had they established their residence among us, and imported directly into our own ports the merchandise which was purchased with the products which they carried away, commercial prosperity would have been in no wise impaired. And indeed they would have been themselves impelled by considerations of personal advantage, to conduct this trade upon the principles of the direct intercourse, had not their largest interests continued to be identified with those of another people.

The impulse given to northern enterprise by the causes just mentioned, was doubtless aided by others arising subsequently, and in some cases originating in the legislation of congress; but the committee regard those which they have just commented upon as first in importance, as in time. The exposition of their nature and of the mode of their operation, seems to indicate the means of relief. It is to draw back to us, as far as practicable, that foreign capital, the employment of which once was, and would again be, productive of internal advantage to the capitalist and to ourselves. It is to enlist in our cause those who producing the articles that are designed for our consumption, have a common interest with ourselves in augmenting that consumption, by diminishing its charges. It is, in fine, to imitate the policy of New York herself, in procuring the establishment by foreign capitalists, of agencies in our ports, for selling the various articles with which they supply us, and purchasing those they receive in return.

Another, and one among the most effectual means of restoring the commerce of the state to its former healthy and flourishing condition, is the improvement of the channels of communication between the Atlantic border and the great West. How vastly this would increase the sum of our exports, and improve the demand for the merchandise imported into our own cities, must be apparent to all who consider with what facility a profitable trade with that immense region might be secured. Our natural advantages of climate and position would enable us, if not to engross, at least to participate largely in the benefits of an intercourse, which is now almost exclusively enjoyed by our more enterprising rivals.

The committee do not deem it necessary to enter into a detailed argument to show the beneficial effects of a liberal system of internal improvement, upon the commercial interests of the state, still less do they propose to discuss the merits of the various schemes which have been suggested from time to time. They leave this duty to the committee to whom this subject has been specially confided. Let it suffice to call attention to the happy results which have attended the adoption of such a system in other states; and to notice an objection that is not unfrequently heard, that the effect of this policy is to tax the general property for the advantage of a favored region. Few measures, of whatever nature, would ever receive the sanction of any legislative body, if their adoption were delayed until it could be ascertained, that the interests of every single individual would be promoted by them. If then it were even conceded that the costs of constructing works of improvement of the kind we have supposed would be partly borne by some, who could derive no benefit from their completion, the objection would only be one which may equally be urged against almost every measure of policy that can be devised. But can it be correctly said that the benefits of those great improvements by which distant sections of country, are, as it were, approximated to each other, and their wealth reciprocally received and imparted, are confined to those whose commodities are sped to their destination through the improved channels of communication? Is the application of steam to the purposes of navigation only advantageous to those whose merchandise is transported in the steam vessel? Are the great inventions of Whitney and Arkwright and Hargrave only beneficial to those whose cotton is submitted to the gin and to the spinning machine? Their happy effects are felt wherever civilisation extends. It is impossible to set limits to the results of those improvements, whether in the arts which produce, or in the means of effecting an exchange of production, by which human labor is abridged, and the wealth of every clime distributed throughout the world. How unfounded then is the objection we have noticed. We are ourselves, at this moment, reaping the advantage of the enterprise of other countries. There is hardly a canal, rail-road or turnpike in the most distinct section of the globe which does not, directly or remotely, advance the prosperity of Virginia.

The promotion of the great agricultural and manufacturing interests of the state, is intimately connected with the objects of this convention. As these important interests, however, have been especially entrusted to other committees, we forbear to say more in relation to them, than to express our sense of their magnitude.

The committee cannot conclude without congratulating the convention upon the bright auguries which are every where seen, of their final and complete success. The spirit which has been recently displayed in this commonwealth—nay, throughout the whole southern country, shows the intense interest felt by our people in the great cause of COMMERCIAL REGENERATION. Let it not be doubted that their acts will be correspondent with their resolutions. Already has one patriotic county, securing the proud distinction of being the first to strike for commercial independence, adopted measures which are in themselves the consummation of their purposes. But though *first*, it will not be *alone*. An example so worthy of imitation, cannot fail of its effect. From the sea-coast to the mountain range, its contagion will be spread, until it shall deprive of power, those who may still retain inclination to disregard its influence.

And is there no warrant for this expectation. Were it even necessary to achieve our object by voluntary sacrifices, have our people ever been remarkable for a disinclination to submit to them? Have they held at a cheap price the interest, the honor, the independence of the state? Have they forgotten their duty, when it might be irksome to perform it; and shall it be doubted that they will be equally mindful of their obligations, when private advantage, and national good conspire to direct their course?

What is it that is expected from them? That they will use the proper means to improve the advantages with which they have been so liberally supplied;—that they will augment the resources of their country—exalt its character, and increase its strength—that they will free their commerce from a taxation, which is not the less severe, that it is voluntary, and discharge a duty to themselves, which apart from all nobler considerations, every principle of selfishness would compel.

More than this will not be demanded—less cannot be expected. It is therefore with the most undoubting confidence, that we anticipate the ultimate triumph of our cause. The indulgence of such an expectation is surely no evidence of an over-sanguine temperament. Success indeed may be delayed. Time may roll on—difficulties may avert—indolence may dissuade and prejudice may revile. But of final success, let us be all assured. Success *must be* the prize of exertion; and exertion cannot flag, when there is so much to stimulate it, in private interest and the general good—in "self love and social"—in all our hopes of the future, and all our recollections of the past.

1. Resolved, That exchanges between nations of their commodities should be effected with the least possible delay and expense; and all other things being equal, that an indirect and circuitous transportation is mutually disadvantageous in subjecting the trade conducted through such channels

to charges and burdens which would be avoided by the establishment of a direct intercourse.

2. Resolved, That the trade by which the people of Virginia are supplied with those articles which they receive in exchange for the products of their industry is, for the most part, an indirect trade, being through the chief ports of the northern states; and that united and unremitted exertions should be made to restore the direct communication which was formerly productive of so much benefit.

3. Resolved, That this convention do recommend that immediate steps be taken to induce manufacturers and other capitalists in foreign countries to establish agencies from commercial connexions among us, in order that the goods exported by them to this country may be sent to their final destination, without being subjected to those expenses arising from intermediate agencies, which are injurious alike to the producer and the consumer.

4. Resolved, That the President appoint a committee of seven, whose duty it shall be, after the adjournment of the convention, to use all means which they may deem necessary and proper to secure the objects contemplated in the next preceding resolution.

5. Resolved, That this convention do recommend to all merchants and traders to give preference in procuring their supplies to the importers in the cities of Virginia and North Carolina, whenever they can be obtained upon as good terms as when purchased abroad; and that the banks of these two states be requested to co-operate with the views of the convention.

6. Resolved, That with a view to the efficient employment of such of our surplus capital as is not invested in commercial pursuits, and to the encouragement of those persons, who with industry and intelligence, are prevented by want of means from engaging in mercantile operations, this convention do earnestly recommend the formation of limited partnerships under the act recently passed by the legislature of Virginia.

7. Resolved, That it be recommended to the importers and exporters of Virginia and North Carolina, to give the preference to vessels belonging to these two states, when the freights can be obtained on terms equally advantageous.

Report of the Committee on Agriculture.

The duty assigned to the committee on agriculture was so suddenly and unexpectedly imposed, that there can be little confidence entertained in its being properly or acceptably discharged. The performance of the duty is therefore attempted with reluctance; and no effort would have been made, but for the respect due to the commands of this convention. It is not that there are not abundant and weighty materials, both of facts and of argument, for a report on this subject, and which might demonstrate the importance of the improvement of agriculture to the commercial and general interests of Virginia, and the necessity for legislative aid being asked, and granted, to promote such improvement. But as your committee are instructed and called upon forthwith to act, without access to authorities on agricultural statistics, or any other materials that would need reference and examination, they are sensible that they can as little do justice to the subject, as they can hope, in this or any better manner, to exert influence on the legislation of the state for the benefit of agriculture.

Besides these difficulties, your committee are at some loss to know the precise kind of inquiry and labor required of them, by the very concise and general terms of the resolution, which directs the formation and action of the committee. And even if they should not mistake the direction of their duty, they may err by overstepping its proper limits. The interests and the claims of agriculture are even more important than any and all others that this body will endeavor to aid; but still your committee must bear in mind that the primary and main design of this convention is to re-establish the commerce of Virginia; and that other objects and interests, however important in other respects, should *here* be treated as merely subsidiary to, or in connexion with, the commercial business and interest of the country.

Whatever can be done to aid the commerce, the manufactures, the canals and railways of the country, in a legitimate and proper manner, will operate to increase the profits, and thereby encourage the improvement of agriculture. Still more truly, because admitting of no exception, may it be affirmed, that whatever will extend the knowledge, and promote the improvement of agriculture, will, in proportion to that direct effect produced, also act indirectly to improve the commercial and manufacturing interests of the country. Neither of these truisms need more than to be announced. From such premises, it follows that the promotion of agricultural instruction and improvement are proper subjects for the notice and favor of this convention, as an important mean for advancing the interests of commerce, the especial object of the assembling of this body. And even on this ground, though it be far less important than others, (which would be out of place if presented *here*,) there would be found sufficient reasons for the legislature to extend to agriculture that fostering care which, by a narrow and niggardly policy, has heretofore been refused.

When aid to agricultural improvement was asked at several of the recent sessions of the legislature of Virginia, the claim was but feebly sustained by its friends, and met with neglect or derision and contempt from all others. The former were at a loss to determine what particular measures of relief to propose, or support; and the latter class have deemed it a sufficient answer to *misapply* the old saying of "*laissez-nous faire,*" declaring that the best thing for agriculture is "to let it alone." Your committee claim to be as true disciples of the free trade school of political economy, as those who thus misapply and abuse this doctrine; and they fully concur in the propriety of leaving all pursuits of industry untrammelled by legislative burdens, and unaided by legislative bounties, to their own direction and their own rewards. But agriculture does not want, nor have its advocates asked for, any pecuniary or other support, except for the purpose of diffusing knowledge, and to induce and extend instruction; and this your committee maintain to be one of the few legitimate and proper subjects for governmental action, even according to the most strict doctrine and limitation of sound political economy. If it be pronounced to be proper that the government should refuse to aid in diffusing light and instruction in agriculture, as a correct deduction from the "let alone" policy, then it is no less necessary that it should abandon, as a matter of principle and consistency, the giving of all or any aid to primary schools and to colleges, for the purpose of literary instruction and education in general.

It would be more difficult within the narrow bounds prescribed by propriety to this report, to answer the friends, than the enemies to the improvement of agriculture by legislative action. In reply to their inquiry, "what can the legislature do to improve agriculture?" your committee will merely state, in general terms, that every means will be useful and profitable, by which light and knowledge will be diffused; and that no other action, no other aid, or boon, is desirable, or would be beneficial. There are so many valuable modes of diffusing agricultural knowledge, that the difficulty is not to find, but to choose among them. Boards of agriculture, agricultural societies and premiums upon a suitable and judicious plan, agricultural schools and experimental farms, and agricultural surveys and publications, each and all, elsewhere have worked admirably to forward the great end in view. But if no more were done at first by legislative action, than the institution of a board of agriculture, as merely an investigating, consulting and advising body, incalculable benefit might be expected to grow out of this one and cheap mode. Such a board (if the system of furnishing aid should go no farther,) might be limited in annual expense to $1500—or barely more than the General Assembly has spent, year after year, merely in the time used for electing an individual to execute the mechanical business of printing their journal and documents—less than the expense of time and money, caused by each single elaborate speech, delivered in that body upon federal relations—not one-fourth part of the annual expense of the geological survey—and perhaps not one-hundredth part of the money wasted in every session in useless or worse than useless debate.

With these views, and in the earnest hope that the recommendation of this highly respectable convention may have more influence on the legislature than any previous expressions of opinion, or petitions, of separate or private individuals, to induce the commencement of the great work of diffusing agricultural instruction and improvement, your committee recommend for the adoption of this convention, the following resolution:

Resolved, as the opinion of this convention, that the commercial and general interest of Virginia and North Carolina, as well as the peculiar interests of the agricultural class, require that legislative aid should be given, promptly and effectually, to the diffusion of agricultural instruction and knowledge, and to the promotion of agricultural improvement.

The foregoing resolution was adopted unanimously; and then the following was moved and adopted:

Resolved, That a committee of five be appointed to wait on the legislature of Virginia, in order to obtain from that body such aid as the agricultural interest of Virginia may require, and that a committee of five be also appointed to wait on the legislature of North Carolina for the like purpose.

Report of the Committee on Banking Capital.

The committee on banks submitted the following report:

At an early period, when bank capital in any part of the Union was small, the southern states enjoyed a large and profitable import trade. They made their exports directly to foreign markets, and in return imported whatever they needed of foreign fabrics. Then, if southern staples were proposed to be purchased on foreign account, or exportations to the states were made by foreign capitalists, the operation was not, as it now is, almost exclusively through northern agency, but in either case the intercourse was immediately and directly with the south. The south did not need any intermediate intercourse with foreign markets; possessing in the number and value of her agricultural staples the elements of foreign trade, and in this respect enjoying advantages over the north, she was her own factor; and her commercial prosperity, and as that involves almost every internal interest, her domestic welfare, were not liable to be affected by the vicissitudes which might occur in the markets of the east or north. An extraordinary change has occurred in the foreign commerce of the country—a change which exhibits the south in the attitude of dependence on the north for the supply of her demand of foreign goods, and what is alike remarkable, for the sale, to a mortifying extent, of her staples, intended for foreign consumption.

The change commenced about the time that the north decided in favor of a policy, which she has ever since steadily encouraged, to her manifest and great benefit, but of which the south was reluctant to avail herself, and has not yet profited by, as she should. That policy is the banking system, and to its powerful agency, as the north has applied it, may be ascribed, in a great degree, her commercial ascendency.

The effect of this policy in concentrating at New York, where it has been appealed to with equal judgment and vigor, a large portion of the entire business of the whole country is obvious. It gave her capital, and capital was alone wanted to secure commercial success. The effect of establishing banks was first to bring together, for commercial purposes, the money of those who should subscribe to its stock, and secondly, to render capital so raised, capable of performing the office of a far greater amount distributed among individuals. As then, an individual of large capital, is an unequal competitor with one of small, so a state or city, which brings to any branch of commerce the advantages of ample means and extended credit, must obtain the superiority of one less favored in these particulars.

By means of her banks, and their large capitals, New York has presented a market in which every commodity may be sold, and in which there is no danger of an overstock by the accumulation of commodities. She has not been under the necessity of restraining her dealings in the products of our own, or of foreign commodities, to some small advance on the actual private capital employed in trade; but has been encouraged to enter largely into whatsoever attracted commercial enterprise, by having it in her power to substitute credit for capital. So far is she in advance of the south, in all the facilities which are essential to commercial activity, that for the want of like facilities, many of our enterprising citizens, of no inconsiderable private fortunes, go thither to profit by advantages denied to them at home.

Your committee do not refer to the commercial ascendency of New York, and to the influence of her bank capital in building up and sustaining it, in any spirit of jealousy or complaint; on the contrary, their object is to direct public attention to what they regard as a valuable and powerful agent in her policy, in the hope that it may lead to more enlightened and liberal opinions among us.

If there be those who would seek for an explanation of northern commercial ascendency in other causes than the one to which the committee has referred, none, it is presumed, can question that it has been an efficient auxiliary. To doubt it, would be to question the connexion between commerce and credit, which the experience, not of this country only, but of the whole world, has ascertained to be inseparable. The inevitable tendency of commerce is to those points where credit may be obtained with the least discouragement, and upon advantageous terms; and without credit, commerce cannot rise far above simple barter, and merchants have neither inducements nor space for their vocation.

It would have been desirable to annex to this report, a table, showing the bank capitals of the great cities of the north and east, and in comparison, the small and inconsiderable capitals of Virginia and North Carolina. This has been omitted for the want of documents from which to compile it. The fact is however notorious, that there is not a point in any part of our country distinguished for commercial activity, which does not possess, in an eminent degree, all the facilities for banking; whilst the bank capital of this state and of North Carolina, has been, and is, not only relatively, but absolutely small, and wholly inadequate to their vast capabilities, and the exigencies of trade.

The legislature of this state, at the session of 1837, authorized an addition to the bank capital, which has been in part only so far realised. The law in respect to a part of this increase has been suspended; and if it should be the pleasure of the legislature at an early day, again to bring the important subject under review, which is most earnestly and respectfully recommended, it is hoped that the terms may be so settled as to attract subscriptions from abroad. The true policy being to recommend her institutions by relieving them from onerous and unnecessary restrictions whilst provisions be made against the abuse and perversion of their powers.

Resolved, as the opinion of this convention, That an increase of banking capital upon principles so liberal as to attract capital from abroad as well as at home, is necessary and indispensable to aid our manufacturers in granting to the southern merchants the same credits that are granted elsewhere, and without which extended credits all the natural and local advantages which enable us to be eminently successful in competition with our northern brethren, are either neutralized, or materially impaired.

Report of the Committee on Manufactures.

The committee very much regret that the necessity for despatch, denies them the opportunity of fulfilling their duties as they would desire. They labor under the further disadvantage of having no precise information in respect to several important points, where many branches of manufactures have been in successful operation upon a large and constantly increasing scale. They are in a measure compelled to limit themselves to an exhibition of the manufacturing condition of one place only. But for this, their apology is, that they have been furnished with no statements from other places. For this, however, there is less cause for regret, as it may be safely concluded of the entire manufacturing interest of the state, that it will advance and flourish, under the same common influence; and that, hitherto, wherever it has been industriously and prudently conducted, it has yielded an adequate return for the capital invested, and made valuable additions to the resources of the state.

The aggregate amount of capital of the several companies of Petersburg engaged in the manufacture of cotton is $772,000. There are 20,000 spindles and 670 looms, requiring 5500 bales of cotton annually. The operatives employed are 1000, whose wages exceed $130,000 per annum. For the machinery and lights, they consume about 5,000 gallons of oil, and for sizing about 1000 barrels of flour. The product is about 3,950,000 yards of cloth and 530,000 lbs. of yarns. Accompanying this report is a table showing the capital of each company, the extent of its business, &c., and by it will be seen that the dividends of two of the companies for the first six months of the present year have been 10 per cent., and of a third company 13 per cent. on its capital. The other companies having been but recently put into operation, have as yet declared no dividends. The dividends of past years have seldom (if ever) fallen under 15 per cent. per annum, and have generally reached beyond 20 per cent. This is an encouraging view of this branch of industry; it has been in existence about ten years, beginning under many discouragements; but showing as it has advanced, its capacity to sustain itself and to reach a state of yet higher and more extended usefulness. And it is obvious to remark, just as it progresses it will elevate the south from the condition of dependence on the industry of the north and east, and furnish the direct and indirect elements of foreign commerce. Whatever therefore tends to encourage cotton manufactures, and for like reasons, whatever tends to encourage all other branches of manufacturing interest, comes directly in aid of the objects of this convention.

Although these manufactories have continued gradually to increase, and we believe the same may be said of all the cotton manufactories of Virginia, yet they have been laboring under *one* great and serious disadvantage, which operates alike upon all the manufactures of the state, whether individuals or incorporated companies; namely, the want of sufficient banking capital, or the application of a portion of that in a different channel, so that the manufacturer who is compelled to pay cash for the raw material and sell on credit may be enabled to reduce into *cash* the paper for which he sells his goods. We believe that the cotton manufacturers throughout the state, agree that, were this want supplied, they have nothing more to ask and nothing to fear from the entire repeal of all protective duties; and still less from any competition with our northern brethren.

The northern manufacturers owing to their liberal system of credits, are enabled to sell their goods on a credit of 8 months, and immediately to have the paper cashed for which they were sold; and thus the southern merchant, who must necessarily sell on a long credit at home, is tempted to buy at the north even at higher prices, and certainly in larger quantities.

The manufacturers of the south having been enabled to succeed thus far, are not the less to expect all the countenance and support from the people and the legislature which can be granted without detriment to, and indeed in common with, the other great interests of the commonwealth.

All that is asked, is to enable them to cash their sales made at 6 to 8 months' time. This granted, and their march is onward; instead of 20 per cent. per annum upon *thousands*, they would make like dividends upon *millions*, and the wealth thus created would presently become a ready and powerful auxiliary to internal improvements, and to all the great interests of the commonwealth.

Your committee conclude this very hasty and imperfect report by a single resolution as follows:

Resolved, as the opinion of this convention that an increase of banking capital upon principles so liberal as to attract capital from abroad as well as at home is necessary and indispensable to aid our manufacturers in granting to the southern merchants the same credits that are granted elsewhere, and without which extended credits all the natural and local advantages, which enable us to be eminently successful in competition with our northern brethren, are either neutralized or materially impaired.

Addenda.

Statistics of the cotton manufactories of Petersburg.

Petersburg Manufacturing Company, incorporated in 1828, capital $120,000; operates 4000 spindles and 106 looms; consumes about 1600 bales cotton annually, when in full operation, 450,000 lbs. of which is sold in the form of yarns, and the balance wove into cloth; employs 200 hands, whose wages amount to more than $25,000 annually.

Last dividend for six months 10 per cent.

Merchant's Manufacturing Company, incorporated in 1832 capital $15,000, operates 4000 spindles and 112 looms; consumes about 1400 bales cotton annually, which produces about 800,000 yards of heavy cloth, besides about 70,000 lbs. sold as yarns; employs about 200 hands, pays more than $25,000 per annum wages.

Last dividend for six months 13 per cent.

Matoaca Manufacturing Company, incorporated in 1835, capital $150,000; operates 4000 spindles and 152 looms; consumes about 800 bales cotton annually, which produces about 850,000 yards cloth; employs 200 hands.

Last dividend for six months 10 per cent.

This company also have a paper mill, capital $75,000; employing at present 30 hands and will very soon employ 30 more.

Ettrick Manufacturing Company, incorporated in 1838, capital $152,000; operates 4000 spindles and 146 looms; consumes about 1,000 bales cotton annually, which produces about 1,000,000 yards cloth; employs 200 hands. But lately gone into operation, and have not yet declared a dividend.

Mechanics' Manufacturing Company, incorporated in 1838, capital $125,000; operates 4000 spindles and 154 looms; will consume when in full operation about 700 bales cotton annually, which will produce 1,000,000 yards cloth; employs 180 hands. But lately gone into operation and has not declared a dividend.

Recapitulation: the whole amount of capital is $772,000; operates 20,000 spindles and 670 looms, consumes 5,500 bales cotton annually, which produce about 3,950,000 yards of cloth and 530,000 lbs. of yarns; employs 1000 hands, whose wages exceeed $130,000. Consumes for machinery and lights, about 5,000 gallons of oil and 1000 barrels flour for sizing.

From the Genesee Farmer.

PRESERVATION OF THE POTATO.

One can form something of an estimate how extensively the potato enters into use as an article of food among the American people, from the complaints we hear from all parts of the country, or at least with very few exceptions, of the partial failure of that crop the present season. We frequently hear people when instituting a comparison between that root and bread, declare they would sooner part with their wheat bread, than with their potato; and these are not the poorer classes, but respectable wealthy people. Now, though we do not carry our affection to this esculent as far as this, yet we are "free to acknowledge" that a good potato is a good thing, and an inferior one, the worst of bad things. An unripe or defective potato, is one of the most indigestible and unwholesome kinds of aliments that can be taken into the stomach, if indeed there is any aliment about it at all; and from the specimens we have seen at numerous tables this year, we have no doubt that many of the cases of illness that have been charged upon hot weather, bad water, *malaria*, and a variety of other things, are justly due to the swallowing potatoes as hard and as heavy, as well as about the size of ounce balls.

The potato, in its original uncultivated state, is decidedly poisonous; and whenever it is used in an imperfect or unripe state, the result is not widely different now. Owing most likely to the hot dry weather, potatoes, this year, are generally of an inferior quality, and hence more pains and care should be taken in selecting those intended for food, and greater attention paid to preserving them, than in years like the last, when among thousands of bushels there was scarcely a defective one. Ireland, on the other side of the Atlantic, and Nova Scotia on this side, are the most celebrated for the excellence of their potatoes, and both have a temperature comparatively low, and an atmosphere moist and humid. If such a climate and temperature is required for the perfection of this root, will not the hot weather we have had the present year, account most satisfactorily for its little value, and also show why its growth is impossible in our more southern states, or still nearer the equinox.

Potatoes almost instinctively shun the light and air. These things so indispensable to the perfection of many other things, are most injurious to the potato, and the grand secret of its preservation lies in the most perfect exclusion of these silent but active agents. To perceive the difference between roots exposed, and those secluded, we have only to take one which has grown partially above ground, and one that has ripened in its proper place. The one will be green on the exterior, hard, heavy, and bitter in the interior, while the other will be of the natural color, farinaceous, and fine flavored. Farmers should take lessons from these facts, and conform their practice to the teachings of nature. In England and Scotland, where most serious complaints have arisen from the failures of the planted tubers, it is acknowledged by all, that roots which are allowed to remain in the ground during the winter never fail of vegetating, and that those secured by pitting are more likely to succeed than those put into cellars, and thus partially exposed to light and air.

The most common method of preserving potatoes is to put them into bins in the cellar, where they are left without any covering or other preparation, and used as wanted. It is also customary to get in as little dirt with them as possible, and one standard of good farming has been the clean state of a farmer's potatoes when deposited in his cellar. For the reasons given above, and from our own experience, we think both these modes of securing potatoes, or preparing them, erroneous. If put into bins, they should be covered as closely as possible from light and air; and if there is dirt enough thrown into the bin to completely fill all the interstices between them, so much the better for the roots. It has been recommended by some potato growers, and the practice is founded in reason, to line the sides of the bins with turf, the lower sides placed inwards, and when the bin was filled, to cover it closely in the same way, and with the same material.

Owing to the severity of our winters, potatoes cannot be allowed to remain where they grow; else their mealiness and freshness would be much increased by allowing those that are to be used the coming season to remain where they are till the spring opens. Since this cannot be, the method of preservation that approaches the nearest to this will be found the best, and this method doubtless is pitting, or as most of our farmers term it, burying in holes in the field. In burying in this way care should be taken not to put too many in a pit, or, in other words, not make the heaps too large. Twenty or twenty-five bushels is quite enough; and some prefer even a smaller number. The cone should be regular so as to be covered equally. The covering of straw and earth first put on should not be too thick, as otherwise the roots will heat, and be injured: but at the latest period allowable, the thickness of the covering should be increased so as effectually to prevent freezing. In covering potatoes in the fall, it should be remembered that the great object of the first covering, is simply to exclude air and light, and preserve them from rain or unfavorable weather, and the last covering is the one to be relied on as a defence against the frost. If the roots are dug and pitted immediately, without unnecessary exposure, and if the ground and the process of covering is properly selected and performed, the potatoes will come out in the spring, in excellent order rather improved than deteriorated by their winter's keeping.

Farmers who are in the habit of making their pork from potatoes, or feeding them extensively to their stock, will undoubtedly see the propriety from the present high prices, of sorting their roots more carefully than they have hitherto done, in order to sell, or preserve, as many as possible. The apprehended scarcity of this root will also prompt to this course; and should induce all to adopt the best and most effectual measures to preserve through the winter uninjured, or, if possible, improved, this root on which so many rely for sustenance.

THE CORN AND SMALLER CROPS OF NANSEMOND COUNTY.

To the Editor of the Farmers' Register.

Clifton, Nansemond Co. Nov. 15, 1838.

I have had it in contemplation for several weeks to address you a few lines, on the state of the crops of our county; but delayed doing so, until this time, so as to be able to ascertain more certainly and distinctly their real state and condition. We are generally very apt to over-estimate our crops; it is not safe, therefore, to judge them until they are got in, when something like certainty may be arrived at. The corn crop (the staple of our county) has been housed, or nearly so; and from the best information I can get, after diligent inquiry of the most intelligent of our farmers, and from my own personal observation, I think I may safely say that it is fully, if not over an average one. The prospect at one period was exceedingly gloomy and unpromising; but, thanks to the Author of all good, our dismal forebodings have been scattered to the winds.

The *truck* crops of the river farms have also yielded well, and sold well. I cannot say, however, that the sweet-potato, which may be justly ranked next in importance to the corn crop, has been altogether as productive as in former years; but, considering all things, it has been a fair yield, and is generally a source of much revenue to the county. It comes, too, at a very convenient time, to pay taxes, and to keep the sheriff at a respectable distance.

It has been estimated by competent judges, that the refuse, or, if I may be allowed the expression, the offal of an acre of suitable land, well cultivated in sweet potatoes, is worth as much as the same quantity of land would produce in corn—an acre of good and suitable land will make, in a tolerable season, one hundred and twenty bushels *marketable* potatoes, which, at fifty cents per bushel, (and for two years the price has ranged from fifty-five to seventy-five cents,) would be sixty dollars—certainly a very handsome profit, admitting the refuse or offal part of the crop to be as valuable as supposed.

The water-melon crop is also entitled to a passing notice. It is one that is easily cultivated, quick over, often very profitable, and has been particularly so this year. A gentleman told me that he sold from twelve acres of land *seven hundred and fifty dollars* worth; and I think it very probable that others did equally as well, if not better.

Cotton as a sale crop has been almost abandoned in our county. The low price and the unsuitableness of our climate to its production, I have no doubt, will ultimately drive it back to the more genial and sunny regions of the south.

It may probably excite the risible faculties of the large wheat growers and tobacco planters of the upper regions of our country, to hear us low-landers prating about our sweet potatoes, water-melons, and other small matters; but whilst we are permitted to enjoy the valuable profits arising from their culture, and the oysters to boot, they are perfectly welcome to the full benefit of the laugh.

When I commenced this letter, I did not design to go further than simply to give you a statement of the condition of our crops; but having a little space left, I will say a few words more. The science of agriculture, the natural employment of man, seems to be making rapid strides towards improvement in many parts of our country, and I hope I may (without the imputation of boasting,) be permitted to say, that few regions are more alive to the great improvements of the age than the county of Nansemond. Her citizens, after slumbering for ages, over almost unrivalled advantages, have at last roused up from their lethargy, and seem disposed to appreciate and to profit by the many advantages that surround them. With a climate mild and temperate, a tolerably good soil, and a vast abundance of all the elements necessary to make it permanently rich and fertile, and a convenient and ready market for every species of produce, down to the very smallest article, surely, her citizens have every inducement to "go ahead" in that career of improvement, which is abroad in the land.

We have established an agricultural society, in the neighborhood of Chuckatuck, and placed at its head one of our most intelligent and enterprising farmers. It is the first society of the kind that ever had existence in our county. They are generally the harbingers of improvement and usefulness, by the rivalry which they excite and the valuable information which they collect and disseminate. JOSHUA M. HARRELL.

[We entirely agree with our correspondent in his high estimation of the advantages of the lands of Nansemond. We have long entertained the opinion, that if a single preliminary improvement were made, these lands would be among the best situated in the U. States, for desirable residence, for the enjoyment of all the comforts and many of the luxuries of life—for agricultural profit—and particularly for increasing that profit by cheap fertilization. The one great improvement which we deem so desirable, is to cut every mill-dam, and dry every mill-pond in the county and its vicinity. That one improvement, by adding to health, physical power, and happiness, would double the value and the income of the lands, and even make meal itself cheaper, by increasing the corn.—ED. FAR. REG.

From the Silk Grower.

SILK-CULTURE.

Messrs. Editors—The worms of my second feeding have just done winding. They are the two crop variety, and were produced from worms fed in the early part of the season, exclusively on the white or Italian mulberry, of four or five summers' growth. They did well, but the expense and trouble of collecting leaves was great, and the cocoons small. But my second crop, as before stated, the product of these first worms, fed entirely on the morus multicaulis, of but one summer's growth, and made cocoons a third, or at least a fourth larger, and more in proportion to the worms hatched. Their being longer going through the various stages, was owing to the late cool weather.

After my first crop of worms had deposited their eggs, I removed them to an ice-house, which is necessary only to produce simultaneous hatching. In a few days they were brought out to the warm air, and as the young ones came they were separated from the eggs, and removed to the feeding shelves, by means of leaves cut in small strips, to which they immediately adhered. In this way each day's hatching may be removed to the shelves allotted them, and kept separate with great facility. The advantage of keeping the worms of each day's hatching by themselves, is great. After being removed, they are suffered to feed on the shelves for a week or ten days, after which hurdles of netting are placing above them, over which fresh leaves are sprinkled, to which they immediately attach themselves, if done in the morning, or when they have eaten their previous food. After this they are regularly cleaned, by means of the hurdle, each succeeding day until they commence rising. As far as my experience extends, I can say that the worm appears to prefer this leaf to all others, is less liable to disease, grows larger, and produces larger cocoons. JAMES B. HOOPER.

Allentown, N. J., Oct. 6, 1838.

From the Silk Grower.

REMOVING MULBERRY TREES.

Mulberry trees which are to be taken out of the ground before winter can be ploughed up easily and expeditiously. Attach two horses to the plough, one before the other; turn a furrow from one side of the row of trees, then run the plough on the opposite side under the roots. They can then be removed by the hands without injury to the plant. Ten thousand can be taken up in this way in an hour.

From the Maine Farmer.

SOUP.

Soup is one of the cheapest, and, to some palates, the most agreeable dish that can be set upon a table, and the following is the most convenient way of preparing it we know of. After taking your meat, potatoes and cabbage from the pot, put into the liquor a little thickening of meal or flour, previously stirred up in cold water, and let it boil up, and you have a soup that is superior to the best French cookery. It is a great waste to throw away the liquor in which meat and vegetables have been boiled.

For the Farmers' Register.

MONTHLY COMMERCIAL REPORT.

Markets have undergone little change during the month. Wheat and flour command nearly the same prices as in October. The former 1,55 to 1,70 per bushel; the latter 8 to 8,25 per barrel. The averages of wheat in England continued to decline, until the duty reached nearly 22 shillings per quarter; but at latest dates prices were again advancing; and during the winter, whilst the Baltic is closed by ice, it is probable the stoppage of supplies from thence may cause the duty to recede again to its minimum. The receipts of flour at New York from the west have been about the same as last year; but these will now cease until the spring, when the supply will be very large. Indian corn has fallen to 90 cts. per bushel. Tobacco continued to advance in England until the price reached 6d. to 12d.—embracing common leaf to fine strips; and in our markets, prices range from $7 to $16—including inferior lugs to good stemmed. Scarcely any of the old crop remains to be brought to market; and the receipts of new are confined chiefly to primings and suckers. The high price inducing the planters to save what has generally been worthless.

The new cotton of Virginia and North Carolina is of inferior quality, and the quantity far short of an average crop; it sells at 10 to 11½ cts., while old commands 11 to 12½ cts. Prices abroad are well sustained, considering the great increase of supply. Few droves of hogs have arrived; and the price is $9,50 to $10 per 100 lbs. Exchange on London 9½ to 10 premium. X.

Nov. 28, 1838.

PLANTING FRUIT TREES.

From the Maine Farmer.

It should be remembered that the proper time for planting fruit seeds and nuts of all kinds is the fall, or at any rate the seeds should be suffered to freeze in the ground during the winter. The action of the frost cracks the hard shell and gives the sprout an opportunity to grow. It is sometimes the case that the frost is not sufficiently severe to crack the shell of hard nuts, such as walnuts, oilnuts peach stones, &c. In such case they should be taken up in the spring and the shell cracked, care being taken not to bruise or injure the meat, and then plant them where your wish them to remain.

ELEMENTS

OF

AGRICULTURAL CHEMISTRY:

BY SIR HUMPHRY DAVY, BART. LL. D., F. R. S. &c.

PREFACE

TO THE FIRST AMERICAN FROM THE FIFTH AND LAST ENGLISH EDITION.

The text of the last English edition of Davy's Elements of Agricultural Chemistry, is precisely the same with that of 1827, which received the latest alterations and improvements made by its illustrious author. But besides that entire text, this, which will be an exact reprint of the last London edition, has the notes then appended by the pen of the author's brother, and co-laborer in chemical investigation, Dr. John Davy.

No American edition of this valuable work has been published from any later than the first English; and even of those early and imperfect editions, few if any copies can now be found for sale. The work, in booksellers' phrase, has long been "out of print;" and there are very few works that so well deserve to be reprinted, or are more essential to the library of every intelligent agriculturist.

It has therefore been thought that it would be an acceptable and important service to the readers of the Farmers' Register, to furnish them with the last edition of this valuable work, in so cheap a form as the pages of this journal will afford.—ED. FAR. REG.

—

ADVERTISEMENT TO THE FIFTH EDITION.

In this edition, the text of the last, to which the advertisement of the author prefixed refers, has been scrupulously preserved unaltered. The only liberty I have taken has been in adding a few foot notes, at the request of the publishers, chiefly relating to facts ascertained since 1826.

JOHN DAVY.

Fort Pitt, Chatham, Nov. 5, 1835.

—

ADVERTISEMENT TO THE FOURTH EDITION.

During ten years, from 1802 to 1812, I had the honor, every session, of delivering courses of lectures before the Board of Agriculture. I endeavored, at all times, to follow in them the progress of discovery; they therefore varied every year; and since they were first published in 1813, some considerable improvements have been made in chemical science, which have rendered many alterations and additions necessary.

I am indebted for much useful information to many gentlemen who have endeavored to improve agriculture, and to apply scientific principles to this most important of the arts; of which acknowledgments will be found in the body of the work. I hope there are no omissions on this head; but should they exist, I trust they will be attributed to defect of recollection, and not to any want of candor or of gratitude.

Where I have derived any specific statements from books, I have always quoted them; but I have not always made references to such doctrines as are become current, the authors of which are well known; and which may be almost considered as the property of all enlightened minds.

In revising this work for the fourth edition, I have been forcibly struck with its imperfections, and I regret that I have been able to do so little to render it more worthy of the approbation of those readers for whom it was designed. My object has been principally to dwell upon practical principles, and practical applications of science; and it is in the farm, and not in the laboratory, that these can be put to the test of experiment; and my duties and pursuits have rendered it impossible for me to do more than point out the path of inquiry—to indicate the road to improvement. The manner in which the work has been received, both in this country and the continent, induces me to hope that its object, however humble, has been to a certain extent attained, and that it has not been without its utility.

I have retained an appendix containing an account of the experiments on grasses instituted by the Duke of Bedford at Woburn, because many of these experiments are alluded to in the body of the work. I am happy, however, to be able to refer my readers to a much fuller and more detailed account of this subject of investigation, in a treatise published by Mr. George Sinclair, entitled *Hort. Gram. Woburnensis*, and which, from the nature of the details, and the singular modesty and clearness with which they are given, is well worthy the perusal of all persons interested in agricultural pursuits.

H. DAVY.

Park Street, January 1, 1827.

LECTURE I.

INTRODUCTION. GENERAL VIEWS OF THE OBJECTS OF THE COURSE, AND OF THE ORDER IN WHICH THEY ARE TO BE DISCUSSED.

It is with great pleasure that I receive the permission to address so distinguished and enlightened an audience on the subject of agricultural chemistry.

That any thing which I am able to bring forward, should be thought worthy the attention of the Board of Agriculture, I consider as an honor; and I shall endeavour to prove my gratitude, by employing every exertion to illustrate this department of knowledge, and to point out its uses.

In attempting these objects, the peculiar state of the inquiry presents many difficulties to a lecturer. Agricultural chemistry has not yet received a regular and systematic form. It has been pursued by competent experimenters for a short time only: the doctrines have not as yet been collected into any elementary treatise; and on an occasion when I am obliged to trust so much to my own arrangements, and to my own limited information, I cannot but feel diffident as to the interest that may be excited, and doubtful of the success of the undertaking. I know, however, that your candor will induce you not to expect any thing like a finished work upon a science as yet in its infancy; and I am sure you will receive with indulgence the first attempt made in this country to illustrate it, by a series of experimental demonstrations.

Agricultural chemistry has for its objects all those changes in the arrangements of matter connected with the growth and nourishment of plants; the comparative values of their produce as food; the constitution of soils; the manner in which lands are enriched by manure, or rendered fertile by the different processes of cultivation. Inquiries of such a nature cannot but be interesting and important, both to the theoretical agriculturist, and to the practical farmer. To the first they are necessary in supplying most of the fundamental principles on which the theory of the art depends. To the second they are useful in affording simple and easy experiments for directing his labors, and for enabling him to pursue a certain and systematic plan of improvement.

It is scarcely possible to enter upon any investigation in agriculture without finding it connected, more or less, with doctrines or elucidations derived from chemistry.

If land be unproductive, and a system of ameliorating it is to be attempted, the sure method of obtaining the object is by determining the cause of its sterility, which must necessarily depend upon some defect in the constituton of the soil, which may be easily discovered by chemical analysis.

Some lands of good apparent texture are yet steril in a high degree; and common observaton and common practice afford no means of ascertaining the cause, or of removing the effect. The application of chemical tests in such cases is obvious; for the soil must contain some noxious principle, which may be easily discovered, and probably easily destroyed.

Are any of the salts of iron present? they may be decomposed by lime. Is there an excess of siliceous sand? the system of improvement must depend on the application of clay and calcareous matter. Is there a defect of calcareous matter? the remedy is obvious. Is an excess of vegetable matter indicated? it may be removed by liming, paring, and burning. Is there a deficiency of vegetable matter? it is to be supplied by manure.

A question concerning the different kinds of limestone to be employed in cultivation often occurs. To determine this fully in the common way of experience, would demand a considerable time, perhaps some years, and trials which might be injurious to crops; but by simple chemical tests the nature of a limestone is discovered in a few minutes; and the fitness of its application, whether as a manure for different soils, or as a cement, determined.

Peat earth of a certain consistence and composition is an excellent manure; but there are some varieties of peats which contain so large a quantity of ferruginous matter as to be absolutely poisonous to plants. Nothing can be more simple than the chemical operation for determining the nature, and the probable uses of a subtance of this kind.

There has been no question on which more difference of opinion has existed, than that of the state in which manure ought to be ploughed into the land; whether recent, or when it has gone through the process of fermentation; and this question is still a subject of discussion. But whoever will refer to the simplest principles of chemistry, cannot entertain a doubt on the subject. As soon as dung begins to decompose, it throws off its volatile parts, which are the most valuable and most efficient. Dung which has fermented, so as to become a mere soft cohesive mass, has generally lost from one third to one half of its most useful constituent elements; and, that it may exert its full action upon the plant, and lose none of its nutritive powers, it should evidently be applied much sooner, and long before decomposition has arrived at its ultimate results.

It would be easy to adduce a multitude of other instances of the same kind; but sufficient, I trust, has been said to prove, that the connection of chemistry with agriculture, is not founded on mere vague speculation, but that it offers principles which ought to be understood and followed, and which, in their progression and application, can hardly fail to be highly beneficial to the community.

A view of the objects in this course of lectures, and of the manner in which they are to be treated, will not, I hope, be considered as an improper introduction. It will inform you what you are to expect; it will afford a general idea of the connection of the different parts of the subject, and of their relative importance; it will enable me to give some historical details of the progress of this branch of knowledge, and to reason from what has been ascertained, concerning what remains to be investigated and discovered.

The phenomena of vegetation must be considered as an important branch of the science of organized nature; but though exalted above inorganic matter, vegetables are yet in a great measure dependent for their existence upon its laws. They receive their nourishment from the external elements; they assimilate it by means of peculiar organs; and it is by examining their physical and chemical constitution, and the substances and powers which act upon them, and the modifications which they undergo, that the scientific principles of agricultural chemistry are obtained.

According to these ideas, it is evident that the study ought to be commenced by some general inquiries into the composition and nature of material bodies, and the laws of their changes. The surface of the earth, the atmosphere, and the water deposited from it, must either together or separately afford all the principles concerned in vegetation; and it is only by examining the chemical nature of these principles, that we are capable of discovering what is the food of plants, and the manner in which this food is supplied and prepared for their nourishment. The principles of the constitution of bodies, consequently, will form the first subject for our consideration.

By methods of analysis dependent upon chemical and electrical instruments dicovered in late times, it has been ascertained that all the varieties of material substances may be resolved into a comparatively small number of bodies, which, as they are not capable of being decompounded, are considered in the present state of chemical knowledge, as elements. The bodies incapable of decomposition at present known are fifty-two.* Of these, forty are metals; eight are inflammable bodies; and five are substances which unite with metals and inflammable bodies, and form with them acids, alkalies, earths, or other analogous compounds. The chemical elements acted upon by attractive powers combine in different aggregates. In their simpler combinations, they produce various crystalline substances, distinguished by the regularity of their forms. In more complicated arrangements, they constitute the varieties of vegetable and animal substances, bear the higher character of organization, and are rendered subservient to the purposes of life. And by the influence of heat, light, and electrical powers, there is a constant series of changes; matter assumes new forms, the destruction of one order of beings tends to the conservation of another; solution and consolidation, decay and renovation, are connected; and whilst the parts of the system continue in a state of fluctuation and change, the order and harmony of the whole remain unalterable.

After a general view has been taken of the nature of the elements, and of the principles of chemical changes, the next object will be the structure and constitution of plants. In all plants there exists a system of tubes or vessels, which in one extremity terminate in roots, and at the other in leaves. It is by the capillary action of the roots that fluid matter is taken up from the soil. The sap, in passing upwards, becomes denser, and more fitted to deposite solid matter: it is modified by exposure to heat, light, and air in the leaves; descends through the bark, in its progress produces new organized matter; and is thus, in its vernal and autumnal flow, the cause of the formation of new parts, and of the more perfect evolution of parts already formed.

* The number is now fifty-four. Since the above was written, thorium has been discovered by Berzelius, and vanadium by Sefstrom; both of them metals, as their termination indicates.—J. D.

In this part of the inquiry, I shall endeavor to connect together into a general view, the observations of the most enlightened philosophers who have studied the physiology of vegetation. Those of Grew, Malphighi, Sennebier, Darwin, De Candolle, Mirbel, and, above all, of Mr. Knight. He is the latest inquirer into these interesting subjects, and his labors have tended most to illustrate this part of the economy of nature.

The chemical composition of plants has, within the last ten years, been elucidated by the experiments of a number of chemical philosopers, both in this and in other countries; and it forms a beautiful part of general chemistry. It is too extensive to be treated of minutely; but it will be necessary to dwell upon such parts of it, as afford practical inferences.

If the organs of plants be submitted to chemical analysis, it is found that their almost infinite diversity of form depends upon different arrangements and combinations of a very few of the elements; seldom more than seven or eight belong to them, and three constitute the greatest part of their organized matter; and according to the manner in which these elements are disposed, arise the different properties of the products of vegetation, whether employed as food, or for other purposes and wants of life.

The value and uses of every species of agricultural produce, are most correctly estimated and applied, when practical knowledge is assisted by principles derived from chemistry. The compounds in vegetables really nutritive as the food of animals, are very few; farina or the pure matter of starch, gluten,sugar, vegetable jelly, oil, and extract.* Of these the most nutritive is gluten; which approaches nearest in its nature to animal matter, and which is the substance that gives to wheat its superiority over other grain. The next in order as to nourishing power is oil, then sugar, then farina; and last of all, gelatinous and extractive matters. Simple tests of the relative nourishing powers of the different species of food, are the relative quantities of these substances that they afford by analysis; and though taste and appearance must influence the consumption of all articles in years of plenty, yet they are less attended to in times of scarcity, and on such occasions this kind of knowledge may be of the greatest importance. Sugar and farina, or starch, are very similar in composition, and are capable of being converted into each other, by simple chemical processes. In the discussion of their relations, I shall detail to you the results of some recent experiments, which will be found possessed of applications both to the economy of vegetation, and to some important processes of manufacture.

All the varieties of substances found in plants, are produced from the sap; and the sap of plants is derived from water, or from the fluids of the soil, and

* Doubt may be entertained of the number being so limited. As the saw-dust of wood is capable of being converted into a kind of bread, by a peculiar process, it is not improbable that, by the digestive powers of animals, nourishment may be derived from substances analogous to saw-dust, as chaff, &c. In the Ionian islands, where cattle are miserably kept during the winter months, they are fed chiefly on straw, and the horses of the farmer on straw and the cuttings of the vine.—J. D.

it is altered by, or combined with, principles derived from the atmosphere. The influence of the soil, of water, and of air, will therefore be the next subject of consideration. Soils in all cases consist of a mixture of different finely divided earthy matters; with animal or vegetable substances in a state of decomposition, and certain saline ingredients. The earthy matters are the true basis of the soil; the other parts, whether natural, or artificially introduced, operate in the same manner as manures. Four earths generally abound in soils; the aluminous, the silicious, the calcareous, and the magnesian. These earths, as I have discovered, consist of highly inflammable metals united to pure air, or oxygen; and they are not, as far as we know, decomposed or altered in vegetation.

The great use of the soil is to afford support to the plant, to enable it to fix its roots, and to derive nourishment by its tubes slowly and gradually, from the soluble and dissolved substances mixed with the earths.

That a particular mixture of the earths is connected with fertility, cannot be doubted: and almost all steril soils are capable of being improved, by a modification of their earthy constituent parts. I shall describe the simplest method as yet discovered of analysing soils, and of ascertaining the constitution and chemical ingredients which appear to be connected with fertility; and on this subject many of the former difficulties of investigation will be found to be removed by recent inquiries.

The necessity of water to vegetation, and the luxuriancy of the growth of plants connected with the presence of moisture in the southern countries of the old continent, led to the opinion so prevalent in the early schools of philosophy, that water was the great productive element, the substance from which all things were capable of being composed, and into which they were finally resolved. The "*ariston men hydor*" of the poet, "water is the noblest," seems to have been an expression of this opinion, adopted by the Greeks from the Egyptians, taught by Thales, and revived by the alchemists in late times. Van Helmont, in 1610, conceived that he had proved, by a decisive experiment, that all the products of vegetables were capable of being generated from water. His results were shown to be fallacious by Woodward in 1691; but the true use of water in vegetation was unknown till 1785; when Mr. Cavendish made the discovery, that it was composed of two elastic fluids or gases, inflammable gas or hydrogen, and vital gas or oxygen.

Air, like water, was regarded as a pure element by most of the ancient philosophers: a few of the chemical inquirers in the sixteenth and seventeenth centuries, formed some happy conjectures respecting its real nature. Sir Kenelm Digby, in 1660, supposed that it contained some saline matter, which was an essential food of plants. Boyle, Hook, and Mayow, between 1665 and 1680, stated, that a small part of it only was consumed in the respiration of animals, and in the combustion of inflammable bodies; but the true statical analysis of the atmosphere is comparatively a recent labor, achieved towards the end of the last century by Scheele, Priestley, and Lavoisier. These celebrated men showed that its principal elements are two gases, oxygen and azote, of which the first is essential to flame, and to the life of animals and that it likewise contains small quantities of aqueous vapor, and of carbonic acid gas; and Lavoisier proved that this last body is itself a compound elastic fluid, consisting of charcoal dissolved in oxygen.

Jethro Tull, in his Treatise on Horse-hoeing, published in 1733, advanced the opinion, that minute earthy particles supplied the whole nourishment of the vegetable world; that air and water were chiefly useful in producing these particles from the land; and that manures acted in no other way than in ameliorating the texture of the soil, in short, that their agency was mechanical. This ingenious author of the new system of agriculture having observed the excellent effects produced in farming, by a minute division of the soil, and the pulverization of it by exposure to dew and air, was misled, by carrying his principles too far. Duhamel, in a work printed in 1754, adopted the opinion of Tull; and stated, that by finely dividing the soil, any number of crops might be raised in succession from the same land. He attempted also to prove, by direct experiments, that vegetables of every kind were capable of being raised without manure. This celebrated horticulturist lived, however, sufficiently long to alter his opinion. The results of his later and most refined observations led him to the conclusion, that no single material afforded the food of plants. The general experience of farmers had long before convinced the unprejudiced of the truth of the same opinion, and that manures were absolutely consumed in the process of vegetation. The exhaustion of soils, by carrying off corn crops from them, and the effects of feeding cattle on lands, and of preserving their manure, offer familiar illustrations of the principle; and several philosophical inquirers, particularly Hassenfratz and Saussure, have shown, by satisfactory experiments, that animal and vegetable matters deposited in soils are absorbed by plants, and become a part of their organized matter. But though neither water, nor air, nor earth, supplies the whole of the food of plants, yet they all operate in the process of vegetation. The soil is the laboratory in which the food is prepared. No manure can be taken up by the roots of plants, unless water is present; and water, or its elements, exist in all the products of vegetation. The germination of seeds does not take place without the presence of air or oxygen gas: and in the sunshine, vegetables decompose the carbonic acid gas of the atmosphere, the carbon of which is absorbed, and becomes a part of their organized matter, and the oxygen gas, the other constituent, is given off;* and, in consequence of a variety of agencies, the economy of vegetation is made subservient to the general order of the system of nature.

It is shown by various researches, that the constitution of the atmosphere has been always the same since the time that it was first accurately analyzed; and this must, in a great measure, de-

* The great accumulation of carbon in forests and in peat mosses, not to lay stress on beds of mineral coal, which there is good reason to consider of vegetable origin, affords demonstrative proof, as it appears to me, of the truth in the text, that plants, in active vegetation and growth, either mediately or immediately derive from the atmosphere carbon, by the decomposition of carbonic acid and the liberation of its oxygen. J. D.

pend upon the powers of plants to absorb or decompose the putrefying or decaying remains of animals and vegetables, and the gaseous effluvia which they are constantly emitting. Carbonic acid gas is formed in a variety of processes of fermentation and combustion, and in the respiration of animals; and, as yet, no other process is known in nature by which it can be consumed, except vegetation. Animals produce a substance which appears to be a necessary food of vegetables; vegetables evolve a principle necessary to the existence of animals; and these different classes of beings seem to be thus connected together in the exercise of their living functions, and to a certain extent made to depend upon each other for their existence. Water is raised from the ocean, diffused through the air, and poured down upon the soil, so as to be applied to the purposes of life. The different parts of the atmosphere are mingled together by winds or changes of temperature, and successively brought in contact with the surface of the earth, so as to exert their fertilizing influence. The modifications of the soil, and the application of manures, are placed within the power of man, as if for the purpose of awakening his industry, and of calling forth his powers.

The theory of the general operation of the more compound manures, may be rendered very obvious by simple chemical principles; but there is still much to be discovered, with regard to the best methods of rendering animal and vegetable substances soluble; with respect to the processes of decomposition, how they may be accelerated or retarded, and the means of producing the greatest effects from the materials employed: these subjects will be attended to in the lecture on manures.

Plants are found by analysis to consist principally of charcoal and aëriform matter. They give out by distillation volatile compounds, the elements of which are pure air, inflammable air, coally matter, and azote, or that elastic substance which forms a great part of the atmosphere, and which is incapable of supporting combustion. These elements they gain, either by their leaves from the air, or by their roots from the soil. All manures from organized substances contain the principles of vegetable matter, which, during putrefaction, are rendered either soluble in water or aëriform—and in these states, they are capable of being assimilated to the vegetable organs. No one principle affords the pabulum of vegetable life; it is neither charcoal nor hydrogen, nor azote, nor oxygen alone; but all of them together, in various states and various combinations. Organic substances, as soon as they are deprived of vitality, begin to pass through a series of changes, which ends in their complete destruction, in the entire separation and dissipation of the parts. Animal matters are the soonest destroyed by the operation of air, heat, and light. Vegetable substances yield more slowly, but finally obey the same laws.* The periods of the application of manures from decomposing animal and vegetable substances depend upon the knowledge of these principles; and I shall be able to produce some new and important facts founded upon them, which I trust will remove all doubt from this part of agricultural theory.

The chemistry of the more simple manures, the manures which act in very small quantities, such as gypsum, alkalies, and various saline substances, has hitherto been exceedingly obscure. It has been generally supposed that these materials act in the vegetable economy in the same manner as condiments or stimulants in the animal economy, and that they render the common food more nutritive. It seems, however, a much more probable idea, that they are actually a part of the true food of plants, and that they supply that kind of matter to the vegetable fibre, which is analogous to the bony matter in animal structures.

The operation of gypsum, it is well known, is extremely capricious in this country, and no certain data have hitherto been offered for its application. There is, however, good ground for supposing that the subject will be fully elucidated by chemical inquiry. Those plants which seem most benefited by its application are plants which always afford it on analysis. Clover, and most of the artificial grasses, contain it; but it exists in very minute quantity only in barley, wheat, and turnips. Many peat ashes, which are sold at a considerable price, consist in great part of gypsum, with a little iron; and the first seems to be their most active ingredient. I have examined several of the soils to which these ashes are successfully applied, and I have found in them no sensible quantity of gypsum. In general, cultivated soils contain sufficient of this substance for the use of the grasses; in such cases, its application cannot be advantageous. For plants require only a certain quantity of manure; an excess may be detrimental, and cannot be useful.

The theory of the operation of alkaline substances is one of the parts of the chemistry of agriculture most simple and distinct. They are found in all plants, and therefore may be regarded as amongst their essential ingredients. From their powers of combination, likewise, they may be useful in introducing various principles into the sap of vegetables, which may be subservient to their nourishment.

The fixed alkalies, which were formerly regarded as elementary bodies, it has been my good fortune to decompose. They consist of pure air, united to highly inflammable metallic substances; but there is no reason to suppose that they are reduced into their elements in any of the processes of vegetation.

In this part of the course I shall dwell at considerable length on the important subject of lime, and I shall be able to offer some novel views.

Slacked lime was used by the Romans for manuring the soil in which fruit-trees grew. This we are informed by Pliny. Marl had been employed by the Britons and the Gauls from the earliest times, as a top-dressing for land. But the precise period in which burnt lime first came into general use in the cultivation of land, is, I believe, unknown. The origin of the application from the early practices is sufficiently obvious; a substance, which had been used with success in gardening, must have been soon tried in farming; and in

* This statement in the text, though correct generally, is not without exception. Some vegetable substances undergo change very rapidly; some animal substances very slowly. The expressed juices of most fruits enter into the vinous fermentation as rapidly, or even more rapidly, at the temperature of 70° Fahr. than the animal fluids do the putrefactive; the white tissues of animals, as tendons, &c. resist change with great pertinacity.—J. D.

countries where marl was not to be found, calcined limestone would be naturally employed as a substitute.

The elder writers on agriculture had no correct notions of the nature of lime, limestone, and marl, or of their effects; and this was the necessary consequence of the imperfection of the chemistry of the age. Calcareous matter was considered by the alchemists as a peculiar earth, which, in the fire became combined with inflammable acid; and Evelyn and Hartlib, and, still later, Lisle, in their works on husbandry, have characterized it merely as a hot manure, of use in cold lands. It is to Dr. Black, of Edinburgh, that our first distinct rudiments of knowledge on the subject are owing About the year 1755, this celebrated professor proved, by the most decisive experiments, that limestone and all its modifications, marbles, chalks, and marls, consist principally of a peculiar earth united to an aërial acid: that the acid is given out in burning, occasioning a loss of more than 40 per cent., and that the lime in consequence becomes caustic.

These important facts immediately applied, with equal certainty, to the explanation of the uses of lime, both as a cement and as a manure. As a cement, lime, applied in its caustic state, acquires its hardness and durability, by absorbing the aërial (or, as it has been since called, carbonic) acid, which always exists in small quantities in the atmosphere; it becomes, as it were, again limestone.

Chalks, calcareous marls, or powdered limestones, act merely by forming an useful earthy ingredient of the soil, and their efficacy is proportioned to the deficiency of calcareous matter, which, in larger or smaller quantities, seems to be an essential ingredient of all fertile soils; necessary, perhaps, to their proper texture, and as an ingredient in the organs of plants.

Burnt lime, in its first effect, acts as a decomposing agent upon animal or vegetable matter, and seems to bring it into a state in which it becomes more rapidly a vegetable nourishment; gradually, however, the lime is neutralized by carbonic acid, and converted into a substance analogous to chalk; but in this case it more perfectly mixes with the other ingredients of the soil, is more generally diffused and finely divided; and it is probably more useful to land than any calcareous substance in its natural state.

The most considerable fact made known, with regard to limestone, within the last few years, is owing to Mr. Tennant. It had been long known, that a particular species of limestone, found in different parts of the north of England, when applied in its burnt and slacked state to land in considerable quantities, occasioned sterility, or considerably injured the crops for many years. Mr. Tennant in 1800, by a chemical examination of this species of limestone, ascertained that it differed from common limestones by containing magnesian earth; and by several experiments he proved, that this earth was prejudicial to vegetation, when applied in large quantities in its caustic state. Under common circumstances, the lime from the magnesian limestone is, however, used in moderate quantities upon fertile soils in Leicestershire, Derbyshire, and Yorkshire, with good effect; and it may be applied in greater quantities to soils containing very large proportions of vegetable matter. Magnesia, when combined with carbonic acid gas seems not to be prejudicial to vegetation, and in soils rich in manure it is speedily supplied with this principle from the decomposition of the manure.

After the nature and operation of manures have been discussed, the next, and the last subject for our consideration, will be some of the operations of husbandry capable of elucidation by chemical principles.

The chemical theory of fallowing is very simple. Fallowing affords a source of riches to the soil, in consequence of the absorption of oxygen and the aqueous principles of the atmosphere, and so tends to produce an accumulation of decomposing matter, which, in the common course of crops, would be employed as it is formed. Yet in highly cultivated soils, under a regular succession of crops, properly manured, this practice can rarely be advantageous: and the cases in which it is really beneficial are for the destruction of weeds, and for cleansing foul soils.

The chemical theory of paring and burning, I shall discuss fully in this part of the course.

It is obvious, that in all cases it must destroy a certain quantity of vegetable matter, and must be principally useful in cases in which there is an excess of this matter in soils. Burning, likewise, renders clays less coherent, and in this way greatly improves their texture, and causes them to be less permeable to water.

The instances in which it must be obviously prejudicial are those of sandy, dry siliceous soils, containing little animal or vegetable matter. Here it can only be destructive, for it decomposes that on which the soil depends for its productiveness.

The advantages of irrigation, though so lately a subject of much attention, were well known to the ancients; and more than two centuries ago the practice was recommended to the farmers of our country by Lord Bacon: "meadow-watering," according to the statements of this illustrious personage, (given in his Natural History, in the article Vegetation,) "acts not only by supplying useful moisture to the grass; but likewise the water carries nourishment dissolved in it, and defends the roots from the effects of cold."

No general principles can be laid down respecting the comparative merit of the different systems of cultivation and the various systems of crops adopted in different districts, unless the chemical nature of the soil, and the physical circumstances to which it is exposed, are fully known. Stiff coherent soils are those most benefited by minute division and aëration, and in the drill system of husbandry these effects are produced to the greatest extent; but still the labor and expense connected with its application in certain districts may not be compensated for by the advantages produced, and there are some stiff soils which must be left in clods when sown with wheat. Moist climates are best fitted for raising the artificial grasses, oats, and broad-leaved crops; stiff aluminous soils, in general, are most adapted for wheat crops, and calcareous soils produce excellent sain-foin and clover.

Nothing is more wanting in agriculture than experiments in which all the circumstances are minutely and scientifically detailed. This art will advance with rapidity in proportion as it becomes exact in its methods. As in physical researches, all the causes should be considered; a difference in the results may be produced, even by the fall of a half an inch of rain more or less in the course of a season, or a few degrees of temperature, or even by a slight difference in the sub-soil, or in the inclination of the land.

Information collected after views of distinct inquiry would necessarily be fitted for inductive reasoning, and capable of being connected with the general principles of science; and a few histories of the results of truly philosophical experiments in agricultural chemistry would be of more value in enlightening and benefiting the farmer, than the greatest possble accumulation of imperfect trials conducted merely in the empirical spirit. It is no unusual occurrence for persons who argue in favor of practice and experience, to condemn generally all attempts to improve agriculture by philosophical inquiries and chemical methods. That much vague speculation may be found in the works of those who have lightly taken up agricultural chemistry, it is impossible to deny. It is not uncommon to find a number of changes rung upon a string of technical terms, such as oxygen, hydrogen, carbon, and azote, as if the science depended upon words rather than upon things. But this is, in fact, an argument for the necessity of the establishment of just principles of chemistry on the subject. Whoever reasons upon agriculture is obliged to recur to this science. He feels that it is scarcely possible to advance a step without it; and if he is satisfied with insufficient views, it is not because he prefers them to accurate knowledge, but generally because they are more current. If a person journeying in the night wishes to avaid being led astray by the ignis fatuus, the most secure method is to carry a lamp in his own hand.

It has been said, and undoubtedly with great truth, that a philosophical chemist would most probably make a very unprofitable business of farming; and this certainly would be the case, if he were a mere philosophical chemist; and unless he had served his apprenticeship to the practice of the art as well as to the theory.* But there is reason to believe that he would be a more successful agriculturist than a person equally uninitiated in farming, but ignorant of chemistry altogether; his science, as far as it went, would be useful to him. But chemistry is not the only kind of knowledge required; it forms a small part of the philosophical basis of agriculture; but it is an important part, and, whenever applied in a proper manner, must produce advantages.

In proportion as science advances, all the principles become less complicated, and consequently more useful. And it is then that their application is most advantageously made to the arts. The common laborer can never be enlightened by the general doctrines of philosophy, but he will not refuse to adopt any practice, of the utility of which he is fully convinced, because it has been founded upon these principles. The mariner can trust to the compass, though he may be wholly unacquainted with the discoveries of Gilbert on magnetism, or the refined principles of that science developed by the genius of Æpinus. The dyer will use his bleaching liquor, even though he is perhaps ignorant not only of the constitution, but even of the name of the substance on which its powers depend. The great purpose of chemical investigation in agriculture ought undoubtedly to be, the discovery of improved methods of cultivation, But to this end general scientific principles and practical knowledge are alike necessary. The germs of discovery are often found in rational speculations; and industry is never so efficacious as when assisted by science.

It is from the higher classes of the community, from the proprietors of land; those who are fitted, by their education, to form enlightened plans, and by their fortunes, to carry such plans into execution: it is from these that the principles of improvement must flow to the laboring classes of the community; and in all cases the benefit is mutual; for the interest of the tenantry must be always likewise the interest of the proprietors of the soil. The attention of the laborer will be more minute, and he will exert himself more for improvement, when he is certain he cannot deceive his employer, and has a conviction of the extent of his knowledge. Ignorance in the possessor of an estate, of the manner in which it ought to be treated, generally leads either to inattention, or injudicious practices in the tenant or the bailiff. "*Agrum pessimum mulctari cujus Dominus non docet sed audit villicum.*"

There is no idea more unfounded than that a great devotion of time, and a minute knowledge of general chemistry, is necessary for pursuing experiments on the nature of soils, or the properties of manures. Nothing can be more easy than to discover whether a soil effervesces, or changes color by the action of an acid, or whether it burns when heated, or what weight it loses by heat; and yet these simple indications may be of great importance in a system of cultivation. The expense connected with chemical inquiries is extremely trifling; a small closet is sufficient for containing all the materials required. The most important experiments may be made by means of a small portable apparatus; a few phials, containing acids, alkalies, and chemical re-agents; some foil and wire of platinum; a lamp, a crucible, some filtrating paper, some funnels and glasses, for receiving products, are all that can be considered as absolutely essential for pursuing useful researches.

It undoubtedly happens in agricultural chemical experiments conducted after the most refined theoretical views, that there are many instances of failure for one of success; and this is inevitable from the capricious and uncertain nature of the causes that operate, and from the impossibility of calculating on all the circumstances that may interfere: but this is far from proving the inutility of such trials; one happy result, which can generally improve the methods of cultivation, is worth the labor of a whole life; and an unsuccessful experiment, well observed, must establish some truth, or tend to remove some prejudice.

Even considered merely as a philosophical science, this department of knowledge is highly worthy of cultivation. For what can be more delightful than to trace the forms of living beings

*Lavoisier is a remarkable example of the advantages which may be derived from the applicaton of science to agriculture, even without a minute knowledge of the art of farming. By following an enlightened system, he is said to have doubled in nine years the produce in grain of his land, whilst he quintupled the number of his flocks.—*Notice sur Lavoisier*, in *Bibliothcque du chimiste*, tom, vii. p. 121.—J. D.

and their adaptations and peculiar purposes; to examine the progress of inorganic matter in its different processes of change, till it attain its ultimate and highest destination,—its subserviency to the purposes of man?

Many of the sciences are ardently pursued, and considered as proper objects of study for all refined minds, merely on account of the intellectual pleasure they afford; merely because they enlarge our views of nature, and enable us to think more correctly with respect to the beings and objects surrounding us. How much more, then, is this department of inquiry worthy of attention, in which the pleasure resulting from the love of truth and of knowledge is as great as in any other branch of philosophy, and in which it is likewise connected with much greater practical benefits and advantages? *"Nihil est melius, nihil uberius, nihil homine libero dignius."*

Discoveries made in the cultivation of the earth are not merely for the time and country in which they are developed, but they may be considered as extending to future ages, and as ultimately tending to benefit the whole human race; as affording subsistence for generations yet to come; as multiplying life, and not only multiplying life, but likewise providing for its enjoyment.

LECTURE II.

OF THE GENERAL POWERS OF MATTER WHICH INFLUENCE VEGETATION. OF GRAVITATION, OF COHESION, OF CHEMICAL ATTRACTION, OF HEAT, OF LIGHT, OF ELECTRICITY, PONDERABLE SUBSTANCES, ELEMENTS OF MATTER, PARTICULARLY THOSE FOUND IN VEGETABLES, LAWS OF THEIR COMBINATIONS AND ARRANGEMENTS.

The great operations of the farmer are directed towards the production or improvement of certain classes of vegetables; they are either mechanical or chemical, and are, consequently, dependent upon the laws which govern common matter. Plants themselves are, to a certain extent, submitted to these laws; and it is necessary to study their effects, both in considering the phenomena of vegetation, and the cultivation of the vegetable kingdom.

One of the most important properties belonging to matter is *gravitation*, or the power by which masses of matter are attracted towards each other. It is in consequence of gravitation that bodies thrown into the atmosphere fall to the surface of the earth, and that the different parts of the globe are preserved in their proper positions. Gravity is exerted in proportion to the quantity of matter. Hence all bodies placed above the surface of the earth fall to it in right lines, which, if produced, would pass through its centre; and a body falling near a high mountain is a little bent out of the perpendicular direction by the attraction of the mountain, as has been shown by the experiments of Dr. Maskelyne on Schehallien.

Gravitation has a very important influence on the growth of plants; and it is rendered probable, by the experiments of Mr. Knight, that they owe the peculiar direction of their roots and branches almost entirely to this force.

That gentleman fixed some seeds of the garden bean on the circumference of a wheel, which in one instance was placed vertically, and in the other horizontally, and made to revolve, by means of another wheel worked by water, in such a manner, that the number of the revolutions could be regulated; the beans were supplied with moisture, and were placed under circumstances favorable to germination. The beans all grew, notwithstanding the violence of revolution, which was sometimes as much as 250 revolutions in a minute on the vertical wheel, which always revolved rapidly, and with little variation of velocity; the radicles, or roots, pointed precisely in the direction of radii in whatever direction they were first placed. The germs took precisely the opposite direction, and pointed to the centre of the wheel, where they soon met each other. Upon the horizontal wheel, the conflicting operation of gravitation and centrifugal force, occasioned the germs to form a cone, more or less obtuse, according to the velocity of the wheel, the radicles always taking a course diametrically opposite to that taken by the germs, and, consequently, pointing as much below as the germs pointed above the plane of the wheel's motion.

These facts afford a rational solution of this curious problem, respecting which different philosophers have given such different opinions; some referring it to the nature of the sap, as De la Hire; others, as Darwin, to the living powers of the plant, and the stimulus of air upon the leaves, and of moisture upon the roots. The effect is now shown to be connected with mechanical causes; and there seems no other power in nature to which it can with propriety be referred, but gravity, which acts universally, and which must tend to dispose the parts to take a uniform direction.*

If plants in general owe their perpendicular direction to gravity, it is evident that the number of plants upon a given part of the earth's circumference cannot be increased by making the surface irregular, as some persons have supposed. Nor can more stalks rise on a hill than on a spot equal to its base; for the slight effect of the attraction of the hill, would be only to make the plants deviate a very little from the perpendicular. Where horizontal layers are pushed forth, as in certain grasses, particularly such as the fiorin, lately brought into notice by Dr. Richardson, more food may, however, be produced upon an irregular surface; but the principle seems to apply strictly to corn crops.

The direction of the radicles and germens is such, that both are supplied with food, and acted upon by those external agents which are necessary for their developement and growth. The roots come in contact with the fluids in the ground; the leaves are exposed to light and air; and the same grand law which preserves the planets in their orbits is thus essential to the functions of vegetable life.

When two pieces of polished glass are pressed together, they adhere to each other, and it requires some force to separate them. This is said to depend upon the *attraction of cohesion*. The same

* Fig. 1. represents the case in which the horizontal wheel performed 250 revolutions.

Fig. 2. represents the form of the experiment when the vertical wheel was made to perform 150 revolutions in a minute.

Fig. 1.

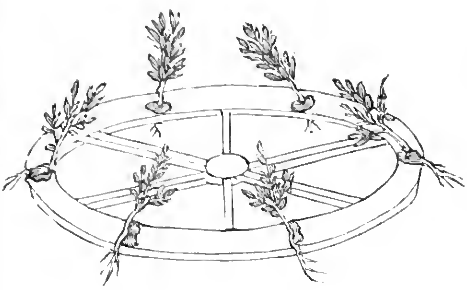

Fig. 2.

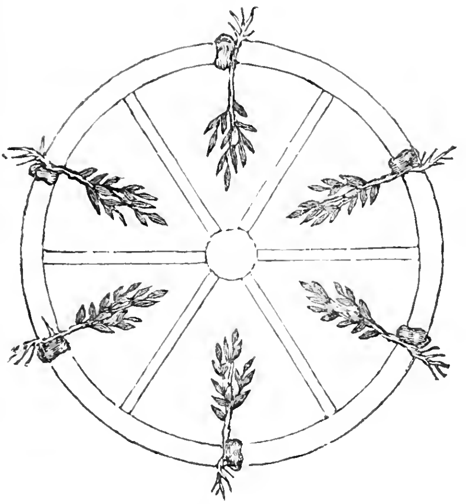

attraction gives the globular form to drops of water, and enables fluids to rise in capillary tubes; and hence it is sometimes called *capillary attraction*. This attraction, like gravitation, seems common to all matter, and may be a modification of the same general force; like gravitation, it is of great importance in vegetation. It preserves the forms of aggregation of the parts of plants, and it seems to be a principal cause of the absorption of fluids by their roots.

If some pure magnesia, the calcined magnesia of druggists, be thrown into distilled vinegar, it gradually dissolves. This is said to be owing to *chemical attraction*, the power by which different species of matter tend to unite into one compound. Various kinds of matter unite with different degrees of force: thus sulphuric acid and magnesia unite with more readiness than distilled vinegar and magnesia; and if sulphuric acid be poured into a mixture of vinegar and magnesia, in which the acid properties of the vinegar have been destroyed by the magnesia, the vinegar will be set free, and the sulphuric acid will take its place. This chemical attraction is likewise called *chemical affinity*. It is active in most of the phenomena of vegetation. The sap consists of a number of ingredients, dissolved in water by chemical attraction; and it appears to be in consequence of the operation of this power, that certain principles derived from the sap are united to the vegetable organs. By the laws of chemical attraction, different products of vegetation are changed, and assume new forms: the food of plants is prepared in the soil; vegetable and animal remains are changed by the action of air and water, and made fluid or aëriform; rocks are broken down and converted into soils; and soils are more finely divided and fitted as receptacles for the roots of plants.

The different powers of attraction tend to preserve the arrangements of matter, or to unite them in new forms. If there were no opposing powers there would soon be a state of perfect quiescence in nature, a kind of eternal sleep in the physical world. Gravitation is continually counteracted by mechanical powers, by projectile motion, or the centrifugal force; and their joint agencies occasion the motion of the heavenly bodies. Cohesion and chemical attraction are opposed by the *repulsive energy* of *heat*, and the harmonious cycle of terrestrial changes is produced by their mutual operations.

Heat is capable of being communicated from one body to other bodies; and its common effect is to expand them, to enlarge them in all their dimensions. This is easily exemplified. A solid cylinder of metal after being heated will not pass through a ring barely sufficient to receive it when cold. When water is heated in a globe of glass having a long slender neck, it rises in the neck; and if heat be applied to air confined in such a vessel inverted above water, it makes its escape from the vessel and passes through the water. Thermometers are instruments for measuring degrees of heat by the expansion of fluids in narrow tubes. Mercury is generally used, of which 100,000 parts at the freezing point of water become 101,835 parts at the boiling point, and on Fahrenheit's scale these parts are divided into 180 degrees. Solids, by a certain increase of heat, become fluids, and fluids gases; or elastic fluids. Thus ice is converted by heat into water, and by still more heat it becomes steam; and heat disappears, or, as it is called, is rendered *latent*, during the conversion of solids into fluids, or fluids into gases, and re-appears, or becomes sensible, when gases become fluids, or fluids solids; hence cold is produced during evaporation, and heat during the condensation of steam.

There are a few exceptions to the law of expansion of bodies by heat, which seem to depend either upon some change in their chemical constitution, or on their becoming crystallised. Clay contracts by heat, which seems to be owing to its giving off water. Cast iron and antimony, when melted, crystallise, in cooling, and expand. Ice is much lighter than water. Water expands a little even before it freezes, and it is of the greatest density at about 41° or 42°, the freezing point being 32°; and this circumstance is of considerable importance in the general economy of nature. The influence of the changes of seasons and of the position of the sun on the phenomena of vegetation demonstrates the effects of heat on the functions of plants. The matter absorbed from the soil must be in a fluid state to pass into their roots, and when the surface is frozen they can derive no nourishment from it. The activity of chemical changes likewise is increased by a certain increase of temperature, and even the rapidity of the ascent of fluids by capillary attraction.

This last fact is easily shown by placing in each of two wine glasses a similar hollow stalk of grass, so bent as to discharge any fluid in the glasses slowly by capillary attraction: if hot water be in one glass. and cold water in the other, the hot water will be discharged much more rapidly than the cold water. The fermentation and decomposition of animal and vegetable substances require a certain degree of heat, which is consequently necessary for the preparation of the food of plants; and, as evaporation is more rapid in proportion as the temperature is higher, the superfluous parts of the sap are most readily carried off at the time its ascent is quickest.

Two opinions are current respecting the nature of heat. By one School it is conceived to be a peculiar subtile fluid, of which the particles repel each other, but have a strong attraction for the particles of other matter. By another it is considered as a motion or vibration of the particles of matter, which is supposed to differ in velocity in different cases, and thus to produce the different degrees of temperature. Whatever decision be ultimately made respecting these opinions, it is certain that there is matter moving in the space between us and the heavenly bodies capable of communicating heat; the motions of which are rectilinear: thus the solar rays produce heat in acting on the surface of the earth. The experiments of Sir W. Herschel have shown that the calorific effects of the solar rays bear no relation to their illuminating powers, the red rays producing a much greater effect of heat than any of the other colored rays; and it appears that there are *invisible* rays distinguished by very different degrees of refrangibility, some of which produce *heat*, and others of which are distinguished by their *chemical* effects.

The different influence of the different solar rays on vegetation have not yet been studied; but it is certain that the rays exercise an influence independent of the heat they produce. Thus plants kept in the dark in a hot-house grow luxuriantly, but they never gain their natural colors; their leaves are white or pale, and their juices watery and peculiarly saccharine.

The earth, when not exposed to the solar rays, is constantly losing heat by radiation, and different soils have their temperature differently diminished by this cause.

When a piece of sealing-wax is rubbed by a woollen cloth, it gains the power of attracting light bodies, such as feathers or ashes. In this state it is said to be *electrical;* and if a metallic cylinder, placed upon a rod of glass, is brought in contact with the sealing-wax, it likewise gains the momentary power of attracting light bodies, so that electricity, like heat, is communicable. When two light bodies receive the same electrical influence, or are electrified by the same body, they repel each other. When one of them is acted on by sealing-wax, and the other by glass that has been rubbed by woollen, they attract each other; hence it is said that bodies similarly electrified repel each other: and bodies dissimilarly electrified attract each other: and the electricity of glass is called vitreous or positive electricity, and that of sealing-wax, resinous or negative electricity.

When, of two bodies made to rub each other, one is found positively electrified, the other is always found negatively electrified, and, as in the common electrical machine, these states are capable of being communicated to metals placed upon rods or pillars of glass. Electricity is produced likewise by the contact of bodies; thus a piece of zinc and of silver give a slight electrical shock when they are made to touch each other, and to touch the tongue; and when a number of plates of copper and zinc, 100 for instance, are arranged in a pile with clothes moistened in salt and water, in the order of zinc, copper, moistened cloth, zinc, copper, moistened cloth, and so on, they form an electrical battery which will give strong shocks and sparks, and which is possessed of remarkable chemical powers. The luminous phenomena produced by common electricity are well known. It would be improper to dwell upon them in this place. They are the most impressive effects occasioned by this agent; and they offer illustrations of lightning and thunder.

Electrical changes are constantly taking place in nature, on the surface of the earth, and in the atmosphere; but as yet the effects of this power in vegetation have not been correctly estimated. It has been shown by experiments made by means of the Voltaic battery (the instrument composed of zinc, copper, and water) that compound bodies in general are capable of being decomposed by electrical powers; and it is probable that the various electrical phenomena occuring in our system must influence both the germination of seeds and the growth of plants. I found that corn sprouted much more rapidly in water positively electrified by the Voltaic instrument than in water negatively electrified; and experiments made upon the atmosphere show that clouds are usually negative; and as, when a cloud is in one state of electricity, the surface of the earth beneath is brought into the opposite state, it is probable that in common cases the surface of the earth is positive.

Different opinions are entertained amongst scientific men respecting the nature of electricity. By some the phenomena are conceived to depend upon a single subtile fluid in excess in the bodies said to be positively electrified, in deficiency in the bodies said to be negatively electrified. A second class suppose the effects to be produced by two different fluids, called by them the vitreous fluid and the resinous fluid; and an hypothesis has been advanced in which they are considered as affections or motions of matter, or an exhibition of attractive powers, similar to those which produce chemical combination and decomposition; but usually exerting their action on masses.*

The power which gives to a bar or needle of steel the property of directing itself to two points of the globe, called north and south poles, depends upon what is called magnetism. It agrees with electricity in many of its laws; but, as far as our researches have hitherto gone, it is most active in its operation on metals and certain of their combinations. Iron, nickel, and cobalt, are most susceptible of magnetic impressions, and in the harder compounds of iron these impressions produce permanent effects; but the recent experiments of M. Arago show, that copper, metals in general, and,

*In a series of experiments on the electricity of the atmosphere, made in Malta during the course of several months, I had ample proof of the truth of the above opinion. Chemical effects were almost constantly taking place, even in serene weather, in a very slight degree. The subject of the experiment was commonly the gelatinous compound of the iodide of potassium and starch; and almost invariably, excepting occasionally in thunder-storms, the iodine was precipitated round the platina wire connected with the earth.—J. D.

probably, all other substances, receive very weak and evanescent magnetism, which seems to differ in intensity for every body. Magnetism is capable of being communicated from bodies endowed with it, to others that do not possess it, and is produced whenever concentrated electricity passes through space, its sphere of action or communication being at right angles to the course of the electricity. Thus a bar of steel, placed transversely over a wire conveying an electrical shock, becomes a magnet. The connexion of magnetism and electricity is of recent discovery, and the fact which served to established it was made known by M. Œrsted, a Danish philosopher. It will ultimately probably tend to a more intimate acquaintance with the nature of these two extraordinary agents. The attractive powers of the magnet may be made use of to show the existence of iron in soils, as will be mentioned more particularly hereafter.

The different powers that have been thus generally described continually act upon common matter so as to change its form, and produce arrangements fitted for the purposes of life. Bodies are either simple or compound. A body is said to be simple, when it is incapable of being resolved into any other forms of matter. Thus, gold or silver, though they may be melted by heat, or dissolved in corrosive menstrua, yet are recovered unchanged in their properties, and they are said to be simple bodies. A body is considered as compound, when two or more distinct substances are capable of being produced from it: thus marble is a compound body, for by a strong heat it is converted into lime, and an elastic fluid is disengaged in the process; and the proof of our knowledge of the true composition of a body is, that it is capable of being reproduced by the same substances as those into which it had been decomposed; thus, by exposing lime for a long while to the elastic fluid disengaged during its calcination, it becomes converted into a substance similar to powdered marble. The term element has the same meaning as simple or undecompounded body; but it is applied merely with reference to the present state of chemical knowledge. It is probable that, as yet, we are not acquainted with any of the true elements of matter: many substances, formerly supposed to be simple, have been lately decompounded, and the chemical arrangement of bodies must be considered as a mere expression of facts, the results of accurate statical experiments.

Vegetable substances in general are of a very compound nature, and consist of a great number of elements, most of which belong likewise to the other kingdoms of nature, and are found in various forms. Their more complicated arrangements are best understood after their simpler forms of combination have been examined.

The number of bodies which I shall consider as at present undecomposed, are, as was stated in the introductory lecture, five acidifying or solvent substances, eight inflammable bodies, and forty metals.*

In most of the inorganic compounds, the nature of which is well known, into which these elements enter, they are combined in definite proportions; so that, if the elements be represented by numbers, the proportions in which they combine are expressed either by those numbers, or by some simple multiples of them.

* Now forty-two.—*Vide note, ante.*

I shall mention, in a few words, the characteristic properties of the most important simple substances, and the numbers representing the proportions in which they combine in those cases where they have been accurately ascertained.

1. *Oxygen* forms about one-fifth of the air of our atmosphere. It is an elastic fluid, at all known temperatures. Its specific gravity is to that of air as 10,967 to 10,000. It supports combustion with much more vividness than common air; so that if a small steel wire or a watch-spring, having a bit of inflamed wood attached to it, be introduced into a bottle filled with the gas, it burns with great splendor. It is respirable. It is very slightly soluble in water. The number representing the proportion in which it combines is 15. It may be made by heating a mixture of the mineral called manganese and sulphuric acid together in a proper vessel, or by heating strongly red lead, or red precipitate of mercury.

2. *Chlorine* is, like oxygen, a permanent elastic fluid. Its color is yellowish green; its smell is very disagreeable; it is not respirable; it supports the combustion of all the common inflammable bodies except charcoal; its specific gravity is to that of air as 24,677 to 10,000; it is soluble in about half its volume of water, and its solution in water destroys vegetable colors. Many of the metals (such as arsenic or copper) take fire spontaneously when introduced into a jar or bottle filled with the gas. Chlorine may be procured by heating together a mixture of spirits of salt, or muriatic acid, and manganese. The number representing the proportion in which this gas enters into combination is 67.

3. *Fluorine*, or the fluoric principle. This substance has such strong tendencies to combination, that as yet no vessels have been found capable of containing it in its pure form. It may be obtained, combined with hydrogen, by applying heat to a mixture of fluor, or Derbyshire spar, and sulphuric acid; and in this state it is an intensely acid compound, a little heavier than water, and which becomes still denser by combining with water. The existence of fluorine as an element is proved by its expulsion from certain compounds by chlorine, and by its transference from place to place. In attempts made to confine it, so as to examine its properties, it always combines with, or decomposes the vessels employed; so that, as yet, its physical qualities are unknown: 16 is an approximation to the number representing it.

4. *Iodine.* This substance is procured from the ashes of marine plants, after the extraction of the carbonate of soda, by acting upon them by sulphuric acid. It appears as a dark-colored solid, having the color and lustre of plumbago: its specific gravity is about 4; that of water being 1. It fuses at a low temperature, and at a heat above that of boiling water becomes a violet-colored gas. It forms an active acid by uniting to hydrogen. The alkaline metals burn, when heated in it. It unites to all the metals upon which its action has been examined.

5. *Brome.* This body has been very recently discovered in sea-water. It is in its nature analogous to iodine, and resembles a compound of these two bodies. It is a dense liquid, and forms an orange-colored gas by a gentle heat.

6. *Hydrogen*, or inflammable air, is the lightest known substance; its specific gravity is to that of air as 732 to 10,000. It burns by the action of an

inflamed taper, when in contact with the atmosphere. The proportion in which it combines is represented by unity, or 1. It is procured by the action of diluted oil of vitriol, or hydro-sulphuric acid on filings of zinc or iron. It is the substance employed for filling air-balloons.

7. *Azote* is a gaseous substance, not capable of being condensed by any known degree of cold: its specific gravity is to that of common air as 9516 to 10,000. It does not enter into combustion under common circumstances, but may be made to unite with oxygen by the agency of electrical fire. It forms nearly four-fifths of the air of the atmosphere; and may be procured by burning phosphorus in a confined portion of air. The number representing the proportion in which it combines is 26.

8. *Carbon* is considered as the pure matter of charcoal, and it may be procured by passing spirits of wine through a tube heated red. It has not yet been fused; but raises in vapour at an intense heat. Its specific gravity cannot be easily ascertained; but that of the diamond, which cannot chemically be distinguished from pure carbon, is to that of water as 3500 to 1000. Charcoal has the remarkable property of absorbing several times its volume of different elastic fluids, which are capable of being expelled from it by heat. The number representing it is 11.4.

9. *Sulphur* is the pure substance so well known by that name: its specific gravity is to that of water as 1990 to 1000. It fuses at about 220° Fahrenheit; and at between 500° and 600° takes fire, if in contact with the air, and burns with a pale blue flame. In this process it dissolves in the oxygen of the air, and produces a peculiar acid elastic fluid. The number representing it is 30.

10. *Phosphorus* is a solid of a pale red color, of specific gravity 1770. It fuses at 90°, and boils at 550°. It is luminous in the air at common temperatures, and burns with great violence at 150°, so that it must be handled with great caution. The number representing it is 222. It is procured by digesting together bone ashes and oil of vitriol, and strongly heating the fluid substance so produced with powdered charcoal.

11. *Boron* is a solid of a dark olive color, infusible at any known temperature. It is a substance very lately discovered, and procured from boracic acid. It burns with brilliant sparks, when heated in oxygen, but not in chlorine. Its specific gravity, and the number representing it, are not yet accurately known.

12. *Silicon** is procured from silica, or the earth of flints, by the action of potassium: it appears as a dark fawn-colored powder, which is inflammable, and which produces silica by combustion. It decomposes water and acids; and detonates when heated with alkaline carbonates. It is more analogous to boron in its properties and chemical habitudes than to any other substance. 32 is an approximation to the number representing silicon.

13. *Selenion*, or, as M. Berzelius, the discoverer, names it, selenium, is a substance which forms a sort of intermediate link between the inflammable solids and the metals. It is semi-transparent, of a red color, a non-conductor of electricity, of specific gravity about 4300.

14. *Platinum* is one of the noble metals, of rather a duller white than silver, and the heaviest body in nature; its specific gravity being 21,500. It is not acted upon by any acid menstrua except such as contain chlorine; it requires an intense degree of heat for its fusion.

15. The properties of gold are well known. Its specific gravity is 19,277. It bears the same relation to acid menstrua as platinum: it is one of the characteristics of both these bodies, that they are very difficultly acted upon by sulphur.

16. *Silver* is of specific gravity 10,400; it burns more readily than platinum or gold, which require the intense heat of electricity. It readily unites to sulphur. The number representing it is 205.

17. *Mercury* is the only known metal fluid at the common temperature of the atmosphere; it boils at 660°, and freezes at 39° below 0. Its specific gravity is 13,560. The number representing it is 380.

18. *Copper* is of specific gravity 8890. It burns, when strongly heated, with red flame, tinged with green. The number representing it is 120.

19. *Cobalt* is of specific gravity 7700. Its point of fusion is very high, nearly equal to that of iron. In its calcined or oxidated state, it is employed for giving a blue color to glass.

20. *Nickel* is of a white color: its specific gravity is 8820. This metal and cobalt agree with iron, in being attractible by the magnet. The number representing nickel is 111.

21. *Iron* is of specific gravity 7700. Its other properties are well known. The number representing it is 103.

22. *Tin* is of specific gravity 7291; it is a very fusible metal, and burns when ignited in the air: the number representing the proportion in which it combines is 110.

23. *Cadmium* is a newly discovered metal, very similar to tin in its sensible properties, of specific gravity about 9000, and is very fusible and volatile.

24. *Zinc* is one of the most combustible of the common metals. Its specific gravity is about 7210. It is a brittle metal under common circumstances; but when heated may be hammered or rolled into thin leaves, and after this operation is malleable. The number representing it is 66.

25. *Lead* is of specific gravity 11,352; it fuses at a temperature rather higher than tin. The number representing it is 398.

26. *Bismuth* is a brittle metal of specific gravity 9,822. It is nearly as fusible as tin; when cooled slowly it crystallises in cubes. The number representing it is 135.

27. *Antimony* is a metal capable of being volatilised by a strong red heat. Its specific gravity is 6,800. It burns, when ignited, with a faint white light. The number representing it is 170.

28. *Arsenic* is of a blueish white color, of specific gravity 8310. It may be procured by heating the powder of common white arsenic of the shops strongly in a Florence flask with oil. The metal raises in vapor, and condenses in the neck of the flask. The number representing it is 90.

29. *Manganesum* may be procured from the mineral called manganese, by intensely igniting it

* According to the more recent experiments of Berzelius, pure silicon is of a dark nut-brown color; a non-conductor of electricity: incombustible even in oxygen gas, and infusible before the blow-pipe. It deflagrates, and even explodes, when thrown into fused hydrate of potash or soda.—J. D.

in a forge mixed with charcoal powder. It is a metal very difficult of fusion, and very combustible: its specific gravity is 6850. The number representing it is 177.

30. *Potassium* is the lightest known metal, being only of specific gravity 850. It fuses at about 150°, and rises in vapour at heat a little below redness. It is a highly combustible substance, takes fire when thrown upon water, burns with great brilliancy, and the product of its combustion dissolves in the water. The number representing it is 75. It may be made by passing fused caustic vegetable alkali, the pure kali of druggists, through iron turnings strongly ignited in a gun barrel, or by the electrization of potash by a strong Voltaic battery.

31. *Sodium* may be made in a similar manner to potassium; soda, or the mineral alkali, being substituted for the vegetable alkali. It is of specific gravity 940. It is very combustible. When thrown upon water, it swims on its surface, hisses violently, and dissolves, but does not inflame. The number representing it is 88.

32. *Lithium* is a metal procured from a newly-discovered mineral alkali, very similar to sodium in its properties.

33. *Barium* has, as yet, been procured only by electrical powers, and in very minute quantities, so that its properties have not been accurately examined. The number representing it appears to be 130.

Strontium the 34th, *Calcium* the 35th, *Magnesium* the 36th, *Aluminum* the 37th, *Zirconum* the 38th, *Glucinum* the 39th, and *Ittrium* the 40th of the undecompounded bodies, like barium, have either not been procured absolutely pure, or only in such minute quantities that their properties are little known; they are formed either by electrical powers, or by the agency of potassium, from the different earths whose names they bear, with the change of the termination in *um;* and the numbers representing them are believed to be 90 strontium, 40 calcium, 29 magnesium, 33 aluminum, 70 zirconum, 39 glucinum, 111 ittrium.

The remaining simple bodies are metals, most of which, like those just mentioned, can only be procured with very great difficulty; and the substances in general from which they are procured are very rare in nature. They are *Palladium, Rhodium, Osmium, Iridium, Columbium, Chromium, Molybdenum, Cerium, Tellurium, Tungstenum, Titanium, Uranium.* The numbers representing these last bodies have not yet been determined with sufficient accuracy to render a reference to them of any utility.

The undecompounded substances unite with each other, and the most remarkable compounds are formed by the combinations of oxygen and chlorine with inflammable bodies and metals; and these combinations usually take place with much energy, and are associated with fire.

Combustion in fact, in common cases, is the process of the solution of a body in oxygen, as happens when sulphur or charcoal is burnt; or the fixation of oxygen by the combustible body in a solid form which takes place when most metals are burnt, or when phosphorus inflames; or the production of a fluid from both bodies, as when hydrogen and oxygen unite to form water.

When considerable quantities of oxygen or of chlorine unite to metals or inflammable bodies, they often produce acids; thus sulphureous, phosphoric, and boracic acids are formed by a union of considerable quantities of oxygen with sulphur, phosphorus, and boron: and muriatic acid gas is formed by the union of chlorine and hydrogen.

When smaller quantities of oxygen or chlorine unite with inflammable bodies or metals, they form substances not acid, and more or less soluble in water; and the metallic oxides, the fixed alkalies, and the earths, all bodies connected by analogies, are produced by the union of metals with oxygen.

The composition of any compounds, the nature of which is well known, may be easily learned from the numbers representing their elements; all that is necessary is to know how many proportions enter into union. Thus *potassa,* or the pure caustic vegetable alkali, consists of one proportion of potassium and one of oxygen, and its constitution is consequently 75 potassium, 15 oxygen.

Carbonic acid is composed of two proportions of oxygen 30, and one of carbon 11·4.

Again, *lime* consists of one proportion of calcium and one of oxygen, and it is composed of 40 of calcium and 15 of oxygen. And *carbonate of lime*, or pure chalk, consists of one proportion of carbonic acid 41·4, and one of lime 55.

Water consists of two proportions of hydrogen 2, and one of oxygen 15; and when water unites to other bodies in definite proportions, the quantity is 17, or some multiple of 17, *i. e.* 34 or 51, or 68, &c.

Soda, or the mineral alkali, contains two proportions of oxygen to one of sodium.

Ammonia, or the volatile alkali, is composed of six proportions of hydrogen and one of azote.

Amongst the earths, *Silica*, or the earth of flints, probably consists of two proportions of oxygen to one of silicon; and *Magnesia, Strontia, Baryta or Barytes, Alumina, Zircona, Glucina,* and *Ittria*, of one proportion of metal and one of oxygen.

The *metallic oxides* in general consist of the metals united to from one to four proportions of oxygen; and there are, in some cases, many different oxides of the same metal; thus there are three oxides of lead; the yellow oxide, or massicot, contains two *proportions* of oxygen; the *red oxide*, or *minium*, three; and the *puce-coloured oxide* four proportions. Again there are two *oxides* of *copper*, the *black* and the *orange;* the black contains two proportions of oxygen, the orange one.

For pursuing such experiments on the composition of bodies as are connected with agricultural chemistry, a few only of the undecompounded substances are necessary; and amongst the compounded bodies, the common acids, the alkalies, and the earths, are the most essential substances. The elements found in vegetables, as has been stated in the introductory lecture, are very few. Oxygen, hydrogen, and carbon constitute the greatest part of their organized matter. Azote, phosphorus, sulphur, manganesum, iron, silicum, calcium, aluminum, and magnesium, likewise in different arrangements, enter into their composition, or are found in the agents to which they are exposed; and these twelve undecompounded substances are the elements, the study of which is of the most importance to the agricultural chemist.

The doctrine of definite combinations, as will be shown in the following lectures, will assist us in gaining just views respecting the composition of plants, and the economy of the vegetable kingdom; but the same accuracy of weight and measure, the same statical results which depend upon the uniformity of the laws that govern dead matter, cannot be expected in operations where the powers of life are concerned, and where a diversity of organs and of functions exists. The classes of definite inorganic bodies, even if we include all the crystalline arrangements of the mineral kingdom, are few, compared with the forms and substances belonging to animated nature. Life gives a peculiar character to all its productions; the power of attraction and repulsion, combination and decomposition, are subservient to it; a few elements, by the diversity of their arrangement, are made to form the most different substances; and similar substances are produced from compounds which, when superficially examined, appear entirely different.

LECTURE III.

ON THE ORGANIZATION OF PLANTS. OF THE ROOTS, TRUNK, AND BRANCHES. OF THEIR STRUCTURE. OF THE EPIDERMIS. OF THE CORTICAL AND ALBURNOUS PARTS. OF LEAVES, FLOWERS, AND SEEDS. OF THE CHEMICAL CONSTITUTION OF THE ORGANS OF PLANTS, AND THE SUBSTANCES FOUND IN THEM. OF MUCILAGINOUS, SACCHARINE, EXTRACTIVE, RESINOUS, AND OILY SUBSTANCES. AND OTHER VEGETABLE COMPOUNDS; THEIR ARRANGEMENTS IN THE ORGANS OF PLANTS, THEIR COMPOSITION, CHANGES, AND USES.

Variety characterises the vegetable kingdom; yet there is an analogy between the forms and the functions of all the different classes of plants, and on this analogy the scientific principles relating to their organization depend.

Vegetables are living structures distinguished from animals by exhibiting no signs of preception, or of voluntary motion; and their organs are either organs of nourishment or of reproduction; organs for the preservation and increase of the individual, or for the multiplication of the species.

In the living vegetable system there are to be considered the exterior form, and the interior constitution.

Every plant examined as to external structure, displays at least four systems of organs—or some analogous parts. First, the *root*. Secondly, the *trunk and branches*, or *stem*. Thirdly, the *leaves*; and, fourthly, the *flowers* or *seeds*.

The *root* is that part of the vegetable which least impresses the eye; but it is absolutely necessary. It attaches the plant to the surface, is its organ of nourishment, and the apparatus by which it imbibes food from the soil. The roots of plants, in their anatomical division, are very similar to the trunk and branches. The root may indeed be said to be a continuation of the trunk terminating in minute ramifications and filaments, and not in leaves.

When the branch or the root of a tree is cut transversely, it usually exhibits three distinct bodies: the bark, the wood, and the pith: and these again are individually susceptible of a new division.

The bark, when perfectly formed, is covered by a thin cuticle or *epidermis*, which may be easily separated. It is generally composed of a number of laminæ or scales, which in old trees are usually in a loose and decaying state. The epidermis is not vascular, and it merely defends the interior parts from injury. In forest trees, and in the larger shrubs, the bodies of which are firm, and of strong texture, it is a part of little importance; but in the reeds, the grasses, canes, and the plants having hollow stalks, it is of great use, and is exceedingly strong, and in the microscope seems composed of a kind of glassy net-work, which is principally siliceous earth.

This is the case in wheat, in the oat, in different species of equisetum, and, above all, in the rattan, the epidermis of which contains a sufficient quantity of flint to give light when struck by steel; or two pieces rubbed together produce sparks. This fact first occurred to me in 1798, and it led to experiments by which I ascertained that siliceous earth existed generally in the epidermis of the hollow plants.

The siliceous epidermis serves as a support, protects the bark from the action of insects, and seems to perform a part in the economy of these feeble vegetable tribes, similar to that performed in the animal kingdom by the shell of the crustaceous insects.

Immediately beneath the epidermis is the *parenchyma*. It is a soft substance, consisting of cells filled with fluid, having almost always a greenish tint. The cells in the parenchymatous part, when examined by the microscope, appear hexagonal. This form, indeed, is that usually affected by the cellular membranes in vegetables, and it seems to be the result of the general reaction of the solid parts, similar to that which takes place in the honeycomb. This arrangement, which has usually been ascribed to the skill and artifice of the bee, seems, as Dr. Wollaston has observed, to be merely the result of the mechanical laws which influence the pressure of cylinders composed of soft materials, the nests of solitary bees being uniformly circular.*

The innermost part of the bark is constituted by the *cortical layers*, and their numbers vary with the age of the tree. On cutting the bark of a tree of several years' standing, the productions of different periods may be distinctly seen, though the layer of every particular year can seldom be accurately defined.

The cortical layers are composed of fibrous parts which appear interwoven, and which are transverse and longitudinal. The transverse are membranous and porous, and the longitudinal are generally composed of tubes.

The functions of the parenchymatous and cortical parts of the bark are of great importance. The tubes of the fibrous parts appear to be the organs that receive the sap; the sells seem destined for the elaboration of its parts, and for the exposure of them to the action of the atmosphere, and the new matter is annually produced in the spring, immediately on the inner surface of the cortical layer of the last year.

---

* My brother told me, that Dr. Wollaston, on further inquiry, relinquished the idea expressed above, and adopted the common opinion regarding the manner in which the hexagonal cells are formed.—J. D.

6

It has been shown by the experiments of Mr. Knight, and those made by other physiologists, that the sap descending through the bark after being modified in the leaves, is the principal cause of the growth of the tree; thus, if the bark is wounded, the principal formation of new bark is on the upper edge of the wound; and when the wood has been removed, the formation of new wood takes place immediately beneath the bark: and every vessel and passage in the bark and wood of trees seems capable of carrying fluids in different and opposite directions, though more readily and copiously in one direction than in others, which offers something analogous to the anastomosis of vessels in animal bodies. A fact noticed by M. Palisot de Beauvois, is explained on this principle. That gentleman separated different portions of cortical layers from the rest of the bark in several trees, and found that in most instances the separated bark grew in the same manner as the bark in its natural state. The experiment was tried with most success on the lime-tree, the maple, and the lilac; the layers of bark were removed in August 1810, and in the spring of the next year, in the case of the maple and the lilac, small annual shoots were produced in the parts where the bark was insulated.*

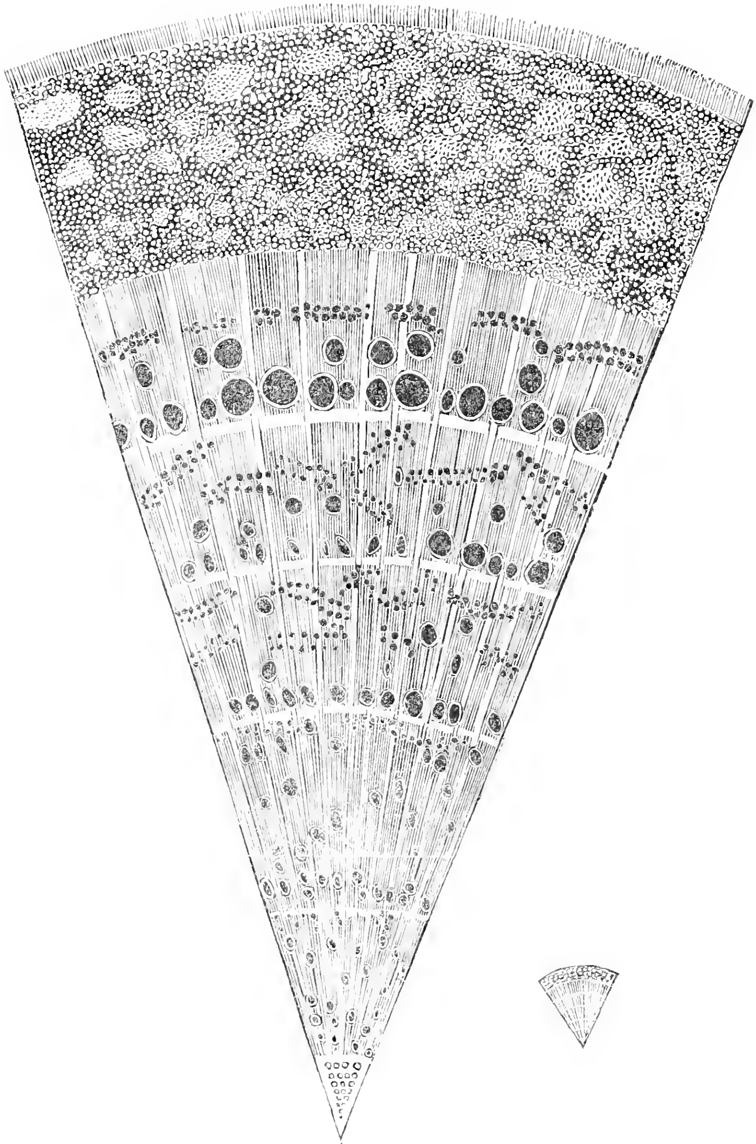
The wood of trees is composed of an external part, called *alburnum* or *sap-wood,* and of an internal part, the *heart-wood.* The alburnum is white, and full of moisture, and in young trees and annual shoots it reaches even to the pith. The alburnum is the great vascular system of the vegetable through which the sap rises, and the vessels in it extend from the leaves to the minutest filaments in the roots.

There is in the alburnum a membranous substance, composed of cells, which are constantly filled with the sap of the plant; and there are in the vascular system several different kinds of tubes; Mirbel has distinguished four species—the *simple tubes,* the *porous tubes,* the *tracheæ,* and the *false tracheæ.*†

* Fig. 3. represents the result of the experiment on the maple. Journal de Phisique, September 1811, p. 210.

† Fig. 4, 5, 6, and 7. represent Mirbel's idea of the simple tubes, the porous tubes, the tracheæ, and the false tracheæ.

Fig. 8, 9, 10.



The tubes, which he has called simple tubes, seem to contain the resinous or oily fluids peculiar to different plants.

The porous tubes likewise contain these fluids; and their use is probably that of conveying them into the sap for the production of new arrangements.

The tracheæ contain fluid matter, which is always thin, watery, and pellucid; and these organs, as well as the false tracheæ, probably carry off water from the denser juices, which are thus enabled to consolidate for the production of new wood.

In the arrangement of the fibres of the wood, there are two distinct appearances. There are series of white and shining laminæ, which shoot from the centre towards the circumference, and these constitute what is called the *silver grain* of the wood.

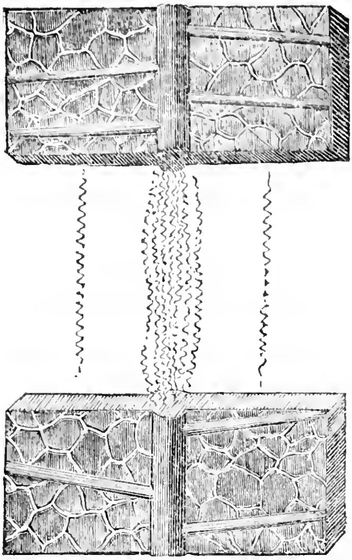
There are likewise numerous series of concentric layers, which are usually called the *spurious grain*, and their number denotes the age of the tree.*

The silver grain is elastic and contractile; and it has been supposed by Mr. Knight, that the contractions produced in it by changes of temperature are the principal causes of the ascent of the sap.

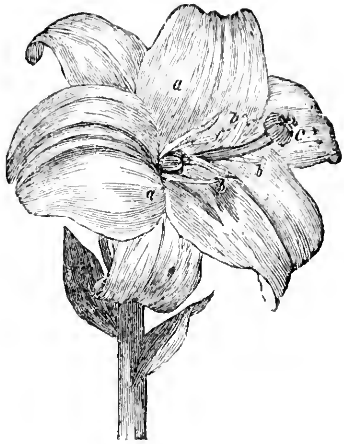
The silver grain is most distinct in forest trees; but even annual shrubs have a system of fibres

* Fig. 8. represents the section of an elm branch, which exhibits the tubular structure and the silver and spurious grain.

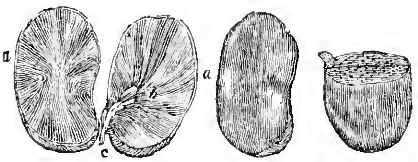
11



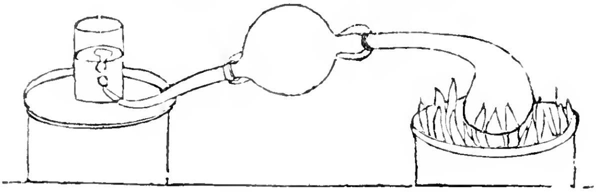
12



13



14



similar to it. The analogy of nature is constant and uniform, and similar effects are usually produced by similar organs.

The *pith* occupies the centre of the wood; its texture is membranous; it is composed of cells, which are circular towards the extremity, and hexagonal in the centre of the substance. In the first infancy of the vegetable, the pith occupies but a small space. It gradually dilates, and in annual shoots and young trees offers a considerable diameter. In the more advanced age of the tree, acted on by the heart-wood, pressed by the new layers of the alburnum, it begins to diminish, and in very old forest trees becomes almost imperceptible.

Many different opinions have prevailed with regard to the use of the pith. Dr. Hales supposed that it was the great cause of the expansion and developement of the other parts of the plant; that being the most interior, it was likewise the most acted upon of all the organs, and that from its reaction the phenomena of their developement and growth resulted.

Linnæus, whose lively imagination was continually employed in endeavors to discover analogies between the animal and vegetable systems, conceived "that the pith performed for the plant the same functions as the brain and nerves in animated beings." He considered it as the organ of irritability, and the seat of life.

The latest discoveries have proved that these two opinions are equally erroneous. Mr. Knight has removed the pith in several young trees, and they continued to live and to increase.

It is evidently, then, only an organ of secondary importance. In early shoots, in vigorous growth, it is filled with moisture; and it is a reservoir, perhaps, of fluid nourishment at the time it is most wanted. As the heart-wood forms, it is more and more separated from the living part, the alburnum; its functions become extinct, it diminishes, dies, and at last disappears.

The *tendrils*, the *spines*, and other similar parts of plants, are analogous in their organization to the branches, and offer a similar cortical and alburnous organization. It has been shown, by the late observations of Mr. Knight, that the directions of tendrils, and the spiral form they assume, depend upon the unequal action of light upon them, and a similar reason has been assigned by M. De Candolle to account for the turning of the parts of plants towards the sun; that ingenious physiologist supposes that the fibres are shortened by the chemical agency of the solar rays upon them, and that, consequently, the parts will move towards the light.*

The *leaves*, the great sources of the permanent beauty of vegetation, though infinitely diversified in their forms, are in all cases similar in interior organization, and perform the same functions.

The alburnum spreads itself from the foot-stalks into the very extremity of the leaf; it retains its vascular system and its living powers; and its peculiar tubes, particularly the tracheæ, may be distinctly seen in the leaf.†

The green membranous substance may be considered as an extension of the parenchyma, and the fine and thin covering as the epidermis. Thus the organization of the roots and branches may be traced into the leaves, which present, however, a more perfect, refined, and minute structure.

One great use of the leaves is for the exposure of the sap to the influence of the air, heat and light. Their surface is extensive, the tubes and cells very delicate, and their texture porous and transparent.

In the leaves much of the water of the sap is evaporated; it is combined with new principles, and fitted for its organizing functions, and probably passes, in its prepared state, from the extreme tubes of the alburnum into the ramifications of the cortical tubes, and then descends through the bark.

On the upper surface of leaves, which is exposed to the sun, the epidermis is thick but transparent, and is composed of matter possessed of little organization, which is either principally earthy, or consists of some homogeneous chemical substance. In the grasses it is partly siliceous, in the laurel resinous, and in the maple and thorn it is principally constituted by a substance analogous to wax. By these arrangements any evaporation, except from the appropriated tubes, is prevented.

On the lower surface the epidermis is a thin transparent membrane full of cavities, and it is probably altogether by this surface that moisture and the principles of the atmosphere necessary to vegetation are absorbed.

If a leaf be turned, so as to present its lower surface to the sun, its fibres will twist so as to bring it as much as possible into its original position; and all leaves elevate themselves on the foot-stalk during their exposure to the solar light, and as it were move towards the sun.

This effect seems, in a great measure, dependent upon the mechanical and chemical agency of light and heat. Bonnet made artificial leaves, which, when a moist sponge was held under the lower surface, and a heated iron above the upper surface, turned exactly in the same manner as the natural leaves. This, however, can be considered only as a very rude imitation of the natural process.

What Linnæus has called the sleep of the leaves, appears to depend wholly upon the suspension of the action of light and heat, and on the operation of moisture.

This singular but constant phenomenon had never been scientifically observed, till the attention of the botanist of Upsal was fortunately directed to it. He was examining particularly a species of lotus, in which four flowers had appeared during the day, and he missed two in the evening; by accurate inspection, he soon discovered that these two were hidden by the leaves, which had closed round them. Such a circumstance could not be lost upon so acute an observer. He immediately took a lantern, went into his garden, and witnessed a series of curious facts before unknown. All the simple leaves of the plants he examined had an arrangement totally different from their arrangement in the day: and the greater number of them were seen closed or folded together.

The sleep of leaves is, in some cases, capable of being produced artificially. De Candolle made this experiment on the sensitive plant. By confining it in a dark place in the day-time, the leaves soon closed; but on illuminating the chamber with many lamps, they again expanded. So sensible were they to the effects of light and radiant heat.

In the greater number of plants the leaves annually decay, and are reproduced, their decay takes place either at the conclusion of the summer, as in very hot climates, when they are no longer supplied with sap, in consequence of the dryness of the soil, and the evaporating powers of heat; or in the autumn, as in the northern climates at the commencement of the frosts. The leaves preserve their functions, in common cases, no longer than there is a circulation of fluids through them. In the decay of the leaf, the color assumed seems to depend upon the nature of the chemical change; and as acids are generally developed, it is usually either reddish-brown or yellow; yet there are great varieties. Thus in the oak, it is bright brown; in the beech, orange; in the elm, yellow; in the vine, red; in the sycamore, dark-brown; in the cornel tree, purple; and in the woodbine, blue.

The cause of the preservation of the leaves of evergreens through the winter is not accurately known. From the experiments of Hales, it appears that the force of the sap is much less in plants of this species, and probably there is a certain degree of motion in it, in warm days, even in winter; their juices are less watery than those of other plants, and probably less liable to be congealed by cold, and certainly not so easy of decomposition; and their vessels are defended by stronger coatings from the action of the elements.

The production of the other parts of the plant takes place at the time the leaves are most vigorously performing their functions. If the leaves are stripped off from a tree in spring, it uniformly dies; and when many of the leaves of forest trees are injured by blasts, or long-continued dryness,

* According to M. De Candolle, in the side of a branch most exposed to light, more carbonic acid is decomposed and more carbon is fixed in its tissue, and consequently it sooner becomes firm and solid than on the other side where least exposed to the agent in question, and therefore the latter elongates in a greater degree than the former. The curvature towards the light is the result. *Vide* Phisiologie Végétale, par M. De Candolle, p. 832. Paris, 1832.—J. D.

† Fig. 11. represents part of a leaf of a vine magnified and cut, so as to exhibit the tracheæ; it is copied, as are also the preceding figures, from Grew's Anatomy of Plants.

the trees always become stag-headed and unhealthy.

The leaves are necessary for the existence of the individual tree; the *flowers* for the continuance of the species. Of all the parts of plants they are the most refined, the most beautiful in their structure, and appear as the master-work of nature in the vegetable kingdom. The elegance of their tints, the variety of their forms, the delicacy of their organization, and the adaptation of their parts, are all calculated to awaken our curiosity, and excite our admiration.

In the flower there are to be observed, 1st, the *calyx*, or green membranous part forming the support for the colored floral leaves. This is vascular, and agrees with the common leaf in its texture and organization; it defends, supports, and nourishes the more perfect parts. 2d, The *corolla*, which consists either of a single piece, when it is called monopetalous; or of many pieces, when it is called polypetalous. It is usually very vivid in in its colors, is filled with an almost infinite variety of small tubes of the porous kind; it incloses and defends the essential parts in the interior, and supplies the juices of the sap to them. These parts are, 3d, the *stamens* and the *pistils*.

The essential part of the stamens are the summits or *anthers*, which are usually circular and of a highly vascular texture, and covered with a fine dust called the *pollen*.

The pistil is cylindrical, and surmounted by the *style;* the top of which is generally round and protuberant.*

In the pistil, when it is examined by the microscope, congeries of spherical forms may usually be perceived, which seem to be the bases of the future seeds.

It is upon the arrangement of the stamens and the pistils that the Linnæan classification is founded. The numbers of the stamens and pistils in the same flower, their arrangements, or their division in different flowers, are the circumstances which guided the Swedish philosopher, and enabled him to form a system admirably adapted to assist the memory, and render botany of easy acquisition; and which, though it does not always associate together the plants most analogous to each other in their general characters, is yet so ingeniously contrived as to denote all the analogies of their most essential parts.

The pistil is the organ which contains the rudiments of the seed; but the seed is never formed as a reproductive germ, without the influence of the pollen, or dust on the anthers.

This mysterious impression is necessary to the continued succession of the different vegetable tribes. It is a feature which extends the resemblances of the different orders of beings, and establishes, on a great scale, the beautiful analogy of nature.

The ancients had observed that different date trees bore different flowers, and that those trees producing flowers which contained pistils bore no fruit, unless in the immediate vicinity of such trees as produced flowers containing stamens. This long-established fact strongly impressed the mind of Malpighi, who ascertained several analogous facts with regard to other vegetables. Grew, however, was the first person who attempted to generalize upon them, and much just reasoning on the subject may be found in his works. Linnæus gave a scientific and distinct form to that which Grew had only generally observed, and has the glory of establishing what has been called the sexual system, upon the basis of minute observations and accurate experiments.

The *seed*, the last production of vigorous vegetation, is wonderfully diversified in form. Being of the highest importance to the resources of nature, it is defended above all other parts of the plant; by soft pulpy substances, as in the esculent fruits; by thick membranes, as in the leguminous vegetables; and by hard shells, or a thick epidermis, as in the palms and grasses.

In every seed there is to be distinguished, 1. the *organ of nourishment;* 2. the nascent plant, or the *plume;* 3. the nascent root, or the *radicle*.

In the common garden bean, the organ of nourishment is divided into two lobes called *cotyledons;* the plume is the small white point between the upper part of the lobes; and the radicle is the small curved cone at their base.*

In wheat, and in many of the grasses, the organ of nourishment is a single part, and these plants are called *monocotyledonous*. In other cases it consists of more than two parts, when the plants are called *polycotyledonous*. In the greater number of instances, it is, however, simply divided into two, and is *dicotyledonous*.

The matter of the seed, when examined in its common state, appears dead and inert: it exhibits neither the forms nor the functions of life. But let it be acted upon by moisture, heat, and air, and its organized powers are soon distinctly developed. The cotyledons expand, the membranes burst, the radicle acquires new matter, descends into the soil, and the plume rises towards the free air. By degrees the organs of nourishment of dicotyledonous plants become vascular, and are converted into seed leaves, and the perfect plant appears above the soil. Nature has provided the elements of germination on every part of the surface, water and pure air and heat are universally active, and the means for the preservation and multiplication of life are at once simple and grand.

To enter into more minute details on the vegetable physiology would be incompatible with the objects of these lectures. I have attempted only to give such general ideas on the subject as may enable the philosophical agriculturist to understand the functions of plants; those who wish to study the anatomy of vegetables, as a distinct science, will find abundant materials in the works of the authors I have quoted, and likewise in the writings of Linnæus, Desfontaines, De Candolle, De Saussure, Bonnet, and Smith.

The history of the peculiarities of structure in the different vegetable classes rather belongs to botanical than agricultural knowledge. As I mentioned in the commencement of this lecture, their organs are possessed of the most distinct analogies, and are governed by the same laws. In the grasses and palms, the cortical layers are larger in proportion than the other parts; but their uses seem to be the same as in forest trees.

In bulbous roots, the alburnous substance forms

* Fig. 12. represents the common lily; *a* the corolla, *bbbbb* the anthers, *c* the pistil.

* Fig. 13. represents the garden bean; *aa* the cotyledons, *b* the plume, *c* the radicle.

the largest part of the vegetable; but in all cases it seems to contain the sap, or solid materials deposited from the sap.

The slender and comparatively dry leaves of the pine and the cedar perform the same functions as the large and juicy leave of the fig-tree, or the walnut.

Even in the cryptogamia class, where no flowers are distinct, still there is every reason to believe that the production of the seed is effected in the same way as in the more perfect plants. The mosses and lichens, which belong to this family, have no distinct leaves, or roots, but they are furnished with filaments which perform the same functions; and even in the fungus and the mushroom there is a system for the absorption and aëration of the sap.

It was stated in the last lecture, that all the different parts of plants are capable of being decomposed into a few elements. Their uses as food, or for the purposes of the arts, depend upon compound arrangements of those elements which are capable of being produced either from their organized parts, or from the juices they contain; and the examination of the nature of these substances is an essential part of agricultural chemistry.

Oils are expressed from the fruits of many plants: resinous fluids exude from the wood; saccharine matters are afforded by the sap; and dying materials are furnished by leaves, or the petals of flowers: but particular processes are necessary to separate the different compound vegetable substances from each other; such as maceration, infusion, or digestion in water, or in spirits of wine: but the application and the nature of these processes will be better understood when the chemical nature of the substances is known; the consideration of them will therefore be reserved for another place in this lecture.

The compound substances found in vegetables are, 1. gum, or mucilage, and its different modifications; 2. starch; 3. sugar; 4. albumen; 5. gluten; 6. gum elastic; 7. extract; 8. tannin; 9. indigo; 10. coloring principles; 11. bitter principles; 12. wax; 13. resins; 14. camphor; 15. fixed oils; 16. volatile oils; 17. woody fibre; 18. acids; 19. alkalies, earths, metallic oxides, and saline compounds.

I shall describe generally the properties and composition of these bodies, and the manner in which they are procured.

1. *Gum* is a substance which exudes from certain trees; it appears in the form of a thick fluid, but soon hardens in the air, and becomes solid: when it is white, or yellowish white, more or less transparent, and somewhat brittle, its specific gravity varies from 1300 to 1490.

There is a great variety of gums, but the best known are gum arabic, gum senegal, gum tragacanth, and the gum of the plum or cherry tree. Gum is soluble in water, but not soluble in spirits of wine. If a solution of gum be made in water, and spirits of wine or alcohol be added to it, the gum separates in the form of white flakes. Gum can be made to inflame only with difficulty; much moisture is given off in the process, which takes place with a dark smoke and feeble blue flame, and a coal remains.

The characteristic properties of gum are its easy solubility in water, and its insolubility in alcohol. Different chemical substances have been proposed for ascertaining the presence of gum, but there is reason to believe that few of them afford accurate results; and most of them (particularly the metallic salts), which produce changes in solutions of gum, may be conceived to act rather upon some saline compounds existing in the gum, than upon the pure vegetable principle.*

Mucilage must be considered as a variety of gum; it agrees with it in its most important properties, but seems to have less attraction for water. According to Hermbstadt, when gum and mucilage are dissolved together in water, the mucilage may be separated by means of sulphuric acid. Mucilage may be procured from linseed, from the bulbs of the hyacinth, from the leaves of the marsh-mallows, from several of the lichens, and from many other vegetable substances.

From the analysis of MM. Gay Lussac and Thenard, it appears that gum arabic contains in 100 parts,

Of Carbon	42.23
Oxygen	50.84
Hydrogen	6.93

With a small quantity of saline and earthy matter.

Or, of carbon	42.23
Oxygen and hydrogen in the proportions necessary to form water	57.77

This estimation agrees very nearly with the definite proportions of 11 of carbon, 10 of oxygen, and 20 of hydrogen.

All the varieties of gum and mucilage are nutritious as food. They either partially or wholly lose their solubility in water by being exposed to a heat of 500° or 600° Fahrenheit, but their nutritive powers are not destroyed unless they are decomposed. Gum and mucilage are employed in some of the arts, particularly in calico-printing: till lately, in this country, the calico-printers used gum arabic; but many of them, at the suggestion of Lord Dundonald, now employ the mucilage from lichens.

2. *Starch* is procured from different vegetables, but particularly from wheat or from potatoes. To make starch from wheat, the grain is steeped in cold water till it becomes soft, and yields a milky juice by pressure; it is then put into sacks of linen, and pressed in a vat filled with water: as long as any milky juice exudes the pressure is continued: the fluid gradually becomes clear, and a white powder subsides, which is starch.

Starch is soluble in boiling water, but not in cold water, nor in spirits of wine.† It is a characteristic property of starch to be rendered blue by iodine.

Starch is more readily combustible than gum; when thrown upon red-hot iron, it burns with a kind of explosion, and scarcely any residuum remains. According to MM. Gay Lussac and Thenard, 100 parts of starch are composed of

* The subacetate of lead appears to be the most delicate test of gum; according to the experiments of Berzelius, the precipitate which it occasions is composed of 38.25 oxide of lead, and 61.75 gum.—J. D.

† Exposed to a temperature a little exceeding 212°, it is rendered soluble in cold water, it becomes very similar to gum; is what De Saussure has called amidine, and is best fitted for the use of the calico-printer. Boiling water has an analogous effect on starch; boiled starch, rendered gelatinous, has the properties of amidine.—J. D.

Carbon, with a small quantity of saline and earthly matter	43.55
Oxygen - - - - -	49.68
Hydrogen - - - - -	6.77
Or,	
Carbon - - - - -	43.55
Oxygen and hydrogen in the proportions necessary to form water	56.45

Supposing this estimation correct, starch may be conceived to be constituted by 15 proportions of carbon, 13 of oxygen, and 26 of hydrogen.

Starch forms a principal part of a number of esculent vegetable substances. Sowans, cassava, salop, sago, all of them owe their nutritive powers principally to the starch they contain.

Starch has been found in the following plants: Burdock, (*Arctium Lappa,*) Deadly Nightshade (*Atropa Belladona,*) Bistort (*Polygonum Bistorta,*) White Bryony (*Bryonia alba,*) Meadow Saffron (*Colchicum autumnale,*) Dropwort (*Spiræa Filipendula,*) Buttercup (*Ranunculus bulbosus,*) Figwort (*Scrophularia nodosa,*) Dwarf Elder (*Sambucus ebulus,*) Common Elder (*Sambucus Nigra,*) Foolstones (*Orchis Morio,*) Alexanders (*Imperatoria Ostruthium,*) Henbane (*Hyoscyamus niger,*) Broad-leaved Dock (*Rumex obtusifolius,*) Sharp-pointed Dock (*Rumex acutus,*) Water Dock (*Rumex aquaticus,*) Wake Robin (*Arum maculatum,*) Salep (*Orchis mascula,*) Flower de Luce or Water-flag (*Iris Pseudacorus,*) Stinking Gladwyn (*Iris fœtidissima,*) Earthnut (*Bunium Bulbocastanum.*)

3. *Sugar* in its purest state is prepared from the expressed juice of the *Saccharum officinarum*, or sugar-cane: the acid in this juice is neutralized by lime, and the sugar is crystallized by the evaporation of the aqueous parts of the juice, and slow cooling: it is rendered white by the gradual filtration of water through it. In the common process of manufacture, the whitening or refining of sugar is only effected in a great length of time; the water being gradually suffered to percolate through a stratum of clay above the sugar. As the coloring matter of sugar is soluble in a saturated solution of sugar, or syrup, it appears that refining may be much more rapidly and economically performed by the action of syrup on colored sugar.* The sensible properties of sugar are well known. Its specific gravity according to Fahrenheit is about 1.6. It is soluble in its own weight of water at 50°; it is likewise soluble in alcohol, but in smaller proportions.

Lavoisier concluded from his experiments, that sugar consists in 100 parts, of

28 carbon,
8 hydrogen,
64 oxygen.

Dr. Thompson considers 100 parts of sugar as composed of 27.5 carbon,
7.8 hydrogen,
64.7 oxygen.

According to the recent experiments of Gay Lussac and Thenard, sugar consists of 42.47 of carbon, and 57.53 of water or its elements.

Lavoisier's and Dr. Thompson's analyses agree very nearly with the proportions of

3 of carbon,
4 of oxygen,
and 8 of hydrogen.

Gay Lussac's and Thenard's estimation gives the same elements as in gum; 11 of carbon, 10 of oxygen, 20 of hydrogen.

It appears from the experiments of Proust, Achard, Goettling, and Parmentier, that there are many different species of sugar ready formed in the vegetable kingdom. The sugar of the American maple, *Acer saccharinum*, is precisely the same as that of the cane. This sugar is used by the North American farmers, who procure it by a kind of domestic manufacture. The trunk of the tree is bored early in spring, to the depth of about two inches; a wooden spout is introduced into the hole; the juice flows for about five or six weeks. A common-sized tree, that is, a tree from two to three feet in diameter, will yield about 200 pints of sap, and every 40 pints of sap afford about a pound of sugar. The sap is neutralized by lime, and deposits crystals of sugar by evaporation.

The *sugar of grapes*, has been lately employed in France as a substitute for colonial sugar. It is procured from the juice of ripe grapes by evaporation and the action of pot-ashes; it is less sweet than common sugar, and its taste is peculiar: it produces a sensation of cold while dissolving in the mouth; and, it is probable, contains a larger portion of water, or its elements.

The roots of the beet (*Beta vulgaris* and *cicla*) afford sugar, by boiling, and the evaporation of the extract: it crystallizes, and does not differ in its properties from the sugar of the cane in France.

Manna, a substance which exudes from various trees, particularly from the *Fraxinus Ornus*, a species of ash, which grows abundantly in Sicily and Calabria, may be regarded as a variety of sugar very analogous to the sugar of grapes.* A substance analogous to manna has been extracted by Fourcroy and Vauquelin from the juice of the common onion (*Allium Cepa.*)

Besides the crystallized and solid sugars, there appears to be a sugar which cannot be separated from water, and which exists only in a fluid form; it constitutes a principal part of melasses or treacle; and it is found in a variety of fruits: it is more soluble in alcohol than solid sugar.

The simplest mode of detecting sugar is that recommended by Margraaf. The vegetable is to be boiled in a small quantity of alcohol; solid sugar, if any exist, will separate during the cooling of the solution.

Sugar has been extracted from the following vegetable substances:—

---

* A French gentleman lately in this country stated to the West India planters, that he was in possession of a very expeditious and economical method of purifying and refining sugar, which he was willing to communicate to them for a very great pecuniary compensation. His terms were too high to be acceded to. Conversing on the subject with Sir Joseph Banks, I mentioned to him that I thought it probable that raw sugar might be easily purified by passing syrup through it; which would dissolve the coloring matter. The same idea seems to have occurred about the same time, or before, to the late Edward Howard, Esq., who proved its efficacy experimentally, and some time before his death took out a patent for various improvements in the manufacture of sugar.

* The substance to which manna owes its sweetness has recently been considered distinct, and called mannite. It is said not to ferment when leaven is added to its solution in water; thus differing from all the varieties of sugar.—J. D.

The sap of the Birch (*Betula alba.*) of the Sycamore (*Acer Pseudoplatanus,*) of the Bamboo (*Arundo Bambos,*) of the Maize (*Zea mays,*) of the Cow Parsnip (*Heracleum Spondylium,*) of the Cocoa-nut tree (*Cocos nucifera,*) of the Walnut tree (*Juglans alba,*) of the American aloes (*Agave Americana,*) of the Dulse (*Fucus Palmatus,*) of the Common Parsnip (*Pastanica sativa,*) of St. John's bread (*Ceratonia Siliqua;*) the fruit of the common Arbutus (*Arbutus Unedo,*) and other sweet-tasted fruits; the roots of the Turnip (*Brassica Rapa,*) of the Carrot (*Daucus Carota*) of Parsley (*Apium petroselinum,*) the flower of the Euxine Rhododendron (*Rhododendron ponticum,*) and from the nectarium of most other flowers.

The nutritive properties of sugar are well known. At the time the British market was over-stocked with this article from the West India islands, proposals were made for applying it as the food of cattle; experiments had been instituted, which proved that they might be fattened by it: but difficulties connected with the duties laid on sugar prevented the plan from being tried to any extent.

4. *Albumen* is a substance which has only lately been discovered in the vegetable kingdom. It abounds in the juice of the Papaw-tree (*Carica papaya:*) when the juice is boiled, the albumen falls down in a coagulated state. It is likewise found in mushrooms, and in different species of funguses.

Albumen, in its pure form, is a thick, glairy, tasteless fluid; precisely the same as the white of the egg; it is soluble in cold water; its solution, when not too diluted, is coagulated by boiling, and the albumen separates in the form of thin flakes. Albumen is likewise coagulated by acids and by alcohol: a solution of albumen gives a precipitate when mixed with a cold solution of nutgalls. Albumen, when burnt, produces a smell of volatile alkali, and affords carbonic acid and water; it is therefore evidently principally composed of carbon, hydrogen, oxygen, and azote.

According to the experiments of Gay Lussac and Thenard, 100 parts of albumen from the white of the egg are composed of

Carbon - -	52.883
Oxygen - -	23.872
Hydrogen - -	7.540
Azote - - -	15.705

This estimation would authorize the supposition that Albumen is composed of 2 proportions of azote, 5 oxygen, 9 carbon, 32 hydrogen.

The principal part of the almond, and of the kernels of many other nuts, appears, from the experiments of Proust, to be a substance analogous to coagulated albumen.

The juice of the fruit of the Ochra (*Hibiscus esculentus,*) according to Dr. Clarke, contains a liquid albumen in such quantities, that it is employed in Dominica, as a substitute for the white of eggs in clarifying the juice of the sugar cane.

Albumen may be distinguished from other substances by its property of coagulating by the action of heat or acids, when dissolved in water. According to Dr. Bostock, when the solution contains only one grain of albumen to 1000 grains of water, it becomes cloudy by being heated.

Albumen is a substance common to the animal as well as to the vegetable kingdom, and much more abundant in the former.

5. *Gluten* may be obtained from wheaten flour by the following process: the flower is to be made into a paste, which is to be cautiously washed, by kneading it under a small stream of water, till the water has carried off from it all the starch; what remains is gluten. It is a tenacious, ductile, elastic substance. It has no taste. By exposure to air, it becomes of a brown color. It is very slightly soluble in cold water; but not soluble in alcohol. When a solution of it in water is heated, the gluten separates in the form of yellow flakes; in this respect it agrees with albumen, but differs from it in being infinitely less soluble in water. The solution of albumen does not coagulate when it contains much less than 1000 parts of albumen: but it appears that gluten requires more than 1000 parts of cold water for its solution.

Gluten, when burnt, affords similar products to albumen, and probably differs very little from it in composition. Gluten is found in a great number of plants: Proust discovered it in acorns, chestnuts, horse-chestnuts, apples, and quinces; barley, rye, peas, and beans; likewise in the leaves of rue, cabbage, cresses, hemlock, borage, saffron, in the berries of the elder, and in the grape. Gluten appears to be one of the most nutritive of the vegetable substances; and wheat seems to owe its superiority to other grain from the circumstance of its containing it in larger quantities.

6. *Gum elastic,* or *Caoutchouc,* is procured from the juice of a tree which grows in the Brazils, called Hævea. When the tree is punctured, a milky juice exudes from it, which gradually deposits a solid substance, and this is gum elastic.

Gum elastic is pliable and soft like leather, and becomes softer when heated. In its pure state, it is white; its specific gravity is 9335. It is combustible, and burns with a white flame, throwing off a dense smoke, with a very disagreeable smell. It is insoluble in water and in alcohol; it is soluble in ether, volatile oils, and in petroleum, and may be procured from ether in an unaltered state. by evaporating its solution in that liquid. Gum elastic seems to exist in a great variety of plants: amongst them are, *Jatropha elastica, Ficus indica, Artocarpus integrifolia,* and *Urceola elastica.*

Bird-lime, a substance which may be procured from the holly, is very analogous to gum elastic in its properties. Species of gum elastic may be obtained from the misletoe, from gum-mastic, opium, and from the berries of the *Smilax caduca,* in which last plant it has been lately discovered by Dr. Barton.

Gum elastic, when distilled, affords volatile alkali, water, hydrogen, and carbon, in different combinations. It therefore consists principally of azote, hydrogen, oxygen, and carbon; but the proportions in which they are combined, have not yet been ascertained. Gum elastic is an indigestible substance, not fitted for the food of animals; its uses in the arts are well known.*

7. *Extract,* or the *extractive principle,* exists in almost all plants. It may be procured in a state of tolerable purity from saffron, by merely infusing it in water, and evaporating the solution. It may likewise be obtained from catechu, or *Terra japonica,* a substance brought from India. This

* By a very careful distillation, a very volatile fluid may be obtained from it, of sp. gr. 0.64: it is a powerful solvent of caoutchouc, and of the resins used in the preparation of varnishes.—J. D.

substance consists principally of astringent matter, and extract; by the action of water upon it, the astringent matter is first dissolved, and may be separated from the extract. Extract is always more or less colored: it is soluble in alcohol and water, but not soluble in ether. It unites with alumina, when that earth is boiled in a solution of extract; and it is precipitated by the salts of alumina, and by many metallic solutions, particularly the solution of muriate of tin.

From the products of its distillation, it seems to be composed principally of hydrogen, oxygen, carbon, and a little azote.

There appears to be almost as many varieties of extract as there are species of plants. The difference of their properties probably in many cases depends upon their being combined with small quantities of other vegetable principles, or to their containing different saline, alkaline, acid, or earthy ingredients. Many dying substances seem to be of the nature of extractive principle; such as the red coloring matter of madder, and the yellow dye, procured from weld.

Extract has a strong attraction for the fibres of cotton or linen, and combines with these substances when they are boiled in a solution of it. The combination is made stronger by the intervention of mordants, which are earthy or metallic combinations that unite to the cloth, and enable the coloring matter to adhere more strongly to its fibres.

Extract, in its pure form, cannot be used as an article of food, but it is probably nutritive when united to starch, mucilage, or sugar.

8. *Tannin*, or the tanning principle, may be procured by the action of a small quantity of cold water on bruised grape-seeds, or pounded gall-nuts; and by the evaporation of the solution to dryness.* It appears as a yellow substance, possessed of a highly astringent taste. It is difficult of combustion. It is very soluble, both in water and alcohol, but insoluble in ether. When a solution of glue, or isinglass, (*gelatine*,) is mixed with an aqueous solution of tannin, the two substances, *i. e.* the animal and vegetable matters, fall down in combination, and form an insoluble precipitate.

When tannin is distilled in close vessels, the principal products are charcoal, carbonic acid, and inflammable gases, with a minute quantity of volatile alkali. Hence its elements seem the same as those of extract, but probably in different proportions. The characteristic property of tannin is its action upon solutions of isinglass or jelly; this particularly distinguishes it from extract, with which it agrees in most other chemical qualities.

There are many varieties of tannin, which probably owe the difference of their properties to combinations with other principles, especially extract, from which it is not easy to free tannin. The purest species of tannin is that obtained from the seeds of the grape; this forms a white precipitate, with solution of isinglass. The tannin from gall-nuts resembles it in its properties. That from sumach affords a yellow precipitate; that from kino a rose-colored; that from catechu a fawn-colored one. The coloring matter of Brazil-wood, which M. Chevreul considers as a peculiar principle, and which he has called *Hematine*, differs from other species of tannin, in affording a precipitate with gelatine, which is soluble in abundance of hot water. Its taste is much sweeter than that of the other varieties of tannin, and it may perhaps be regarded as a substance intermediate between tannin and extract.

Tannin is not a nutritive substance, but is of great importance in its application to the art of tanning. Skin consists almost entirely of jelly or *gelatine*, in an organized state, and is soluble by the long-continued action of boiling water. When skin is exposed to solutions containing tannin, it slowly combines with that principle; its fibrous texture and coherence are preserved; it is rendered perfectly insoluble in water, and is no longer liable to putrefaction: in short, it becomes a substance in chemical composition precisely analogous to that furnished by the solution of jelly and the solution of tannin.

In general, in this country, the bark of the oak is used for affording tannin in the manufacture of leather: but the barks of some other trees, particularly the Spanish chestnut, have lately come into use. The following table will give a general idea of the relative value of different species of barks. It is founded on the result of experiments made by myself.

Table of numbers exhibiting the quantity of Tannin afforded by 480 lbs. of different Barks, which express nearly their relative values.

	LB.
Average of entire Bark of middle-sized Oak, cut in spring	29
" " " of Spanish Chestnut - -	21
" " " of Leicester Willow, large size - - -	33
" " " of Elm - - -	13
" " " of Common Willow, large	11
" " " of Ash - - -	16
" " " of Beech - - -	10
" " " of Horse Chestnut -	9
" " " of Sycamore - -	11
" " " of Lombardy Poplar -	15
" " " of Birch - -	8
" " " of Hazel - -	14
" " " of Black Thorn - -	16
" " " of Coppice Oak - -	32
" " " of Oak, cut in autumn -	21
" " " of Larch, cut in autumn -	8
White interior cortical layers of Oak Bark - -	72

The quantity of the tannin principle in barks differs in different seasons; when the spring has been very cold the quantity is smallest. On an average, 4 or 5 lbs. of good oak bark are required to form 1 lb. of leather. The inner cortical layers in all barks contain the largest quantity of tannin. Barks contain the greatest proportion of tannin at the time the buds begin to open—the smallest quantity in winter.

The extractive or coloring matters found in barks, or in substances used in tanning, influence the quality of leather. Thus skin tanned with gall-nuts is much paler than skin tanned with oak bark, which contains a brown extractive matter. Leather made from catechu is of a reddish tint. It is probable that in the process of tanning, the matter of skin and the tanning principle first enter into union, and that the leather, at the moment of its formation, unites to the extractive matter.

In general, skins in being converted into leather increase in weight about one-third; * and the ope-

* In the purest form in which it has been obtained by M. Pelouze, it is colorless, has distinct acid properties, and is converted into gallic acid by an absorption of oxygen on exposure to the atmosphere. The term tannic acid has recently been applied to it.—J. D.

* This estimation must be considered as applying to *dry* skin and *dry* leather.

ration is most perfect when they are tanned slowly. When skins are introduced into very strong infusions of tannin, the exterior parts immediately combine with that principle, and defend the interior parts from the action of the solution: such leather is liable to crack and to decay by the action of water.

The precipitates obtained from infusions containing tannin by isinglass, when dried, contain at a medium rate about 40 per cent. of vegetable matter. It is easy to obtain the comparative value of different substances for the use of the tanner, by comparing the quantities of precipitate afforded by infusions of given weights mixed with solutions of glue or isinglass.

To make experiments of this kind, an ounce or 180 grains of the vegetable substance, in coarse powder, should be acted upon by half a pint of boiling water. The mixture should be frequently stirred, and suffered to stand 24 hours; the fluid should then be passed through a fine linen cloth, and mixed with an equal quantity of solution of gelatine, made by dissolving glue, jelly, or isinglass, in hot water, in the proportion of a drachm of glue or isinglass, or six table-spoonfuls of jelly, to a pint of water. The precipitate should be collected by passing the mixture of the solution and infusion through folds of blotting-paper, and the paper exposed to the air till its contents are quite dry. If pieces of paper of equal weights are used, in cases in which different vegetable substances are employed, the difference of the weights of the papers, when dried, will indicate with tolerable accuracy the quantities of tannin contained by the substances, and their relative value, for the purposes of manufacture. Four-tenths of the increase of weight, in grains, must be taken, which will be in relation to the weights in the table.

Besides the barks already mentioned, there are a number of others which contain the tanning principle. Few barks, indeed, are entirely free from it. It is likewise found in the wood and leaves of a number of trees and shrubs, and is one of the most generally diffused of the vegetable principles.

A substance very similar to tannin has been formed by Mr. Hatchett, by the action of heated diluted nitric acid on charcoal, and evaporation of the mixture to dryness. From 100 grains of charcoal Mr. Hatchett obtained 120 grains of artificial tannin, which, like natural tannin, possessed the property of rendering skin insoluble in water.

Both natural and artificial tannin form compounds with the alkalies and the alkaline earths; and these compounds are not decomposable by skin. The attempts that have been made to render oak bark more efficient as a tanning material by infusion in lime water, are consequently founded on erroneous principles. Lime forms with tannin a compound not soluble in water.

The acids unite to tannin, and produce compounds that are more or less soluble in water. It is probable that in some vegetable substances tannin exists combined with alkaline or earthy matter; and such substances will be rendered more efficacious for the use of the tanner by the action of diluted acids.

9. *Indigo* may be procured from woad (*Isatis tinctoria,*) by digesting alcohol on it, and evaporating the solution. White crystalline grains are obtained, which gradually become blue by the action of the atmosphere: these grains are the substance in question.

The indigo of commerce is principally brought from America. It is procured from the *Indigofera argentea*, or wild indigo, the *Indigofera disperma*, or Guatimala indigo, and the *Indigofera tinctoria*, or French indigo. It is prepared by fermenting the leaves of those trees in water. Indigo, in its common form, appears as a fine deep blue powder.* It is insoluble in water, and but slightly soluble in alcohol: its true solvent is sulphuric acid: 8 parts of sulphuric acid dissolve 1 part of indigo; and the solution diluted with water forms a very fine blue dye.

Indigo by its distillation affords carbonic acid gas, water, charcoal, ammonia, and some oily and acid matter: the charcoal is in very large proportion. Pure indigo, therefore, most probably consists of carbon, hydrogen, oxygen, and azote.

Indigo owes its blue color to combination with oxygen. For the uses of the dyers, it is partly deprived of oxygen, by digesting it with orpiment and lime water, when it becomes soluble in the lime water, and of a greenish color. Cloths steeped in this solution combine with the indigo; they are green when taken out of the liquor, but become blue by absorbing oxygen when exposed to air.

Indigo is one of the most valuable and most extensively used of the dying materials.

10. There are a number of coloring principles found in different vegetable productions, the properties of which are less marked than those of indigo, and the separation more difficult. The coloring matters of carthamus and madder are the most fixed amongst the red vegetable colors. A number of vegetable substances are rendered red by the action of acids, and green by that of alkalies. They all seem to be composed of different proportions of hydrogen, oxygen, and carbon; but are so liable to change, that few distinct experiments have been made upon their nature. In dying, they are usually applied to cloths prepared for receiving them by combination with certain saline or metallic preparations called mordants; and, in consequence of the triple union formed between the cloth, the mordant, and the coloring matter, the tint is modified, or changed, and rendered more permanent.

11. The *bitter principle* is very extensively diffused in the vegetable kingdom; it is found abundantly in the hop (*Humulus Lupulus*), in the common broom (*Spartium scoparium*), in the chamomile (*Anthemis nobilis*), and in *Quassia amara* and *excelsa*. It is obtained from those substances by the action of water or alcohol, and evaporation. It is usually of pale yellow color; its taste is intensely bitter. It is very soluble, both in water and alcohol; and has little or no action on alkaline, acid, saline, or metallic solution.

An artificial substance, similar to the bitter principle, has been obtained by digesting diluted nitric acid on silk, indigo, and the wood of the white willow. This substance has the property of dying cloth of a bright yellow color; it differs

* By a carefully regulated temperature, it may be sublimed without decomposition, and obtained in a pure crystalline state.—J. D.

from the natural bitter principle in its power of combining with the alkalies; in union with the fixed alkalies, it constitutes crystallized bodies, which have the property of detonating by heat or percussion.

The natural bitter principle is of great importance in the art of brewing; it checks fermentation, and preserves fermented liquors; it is likewise used in medicine.

The bitter principle, like the narcotic principle, appears to consist principally of carbon, hydrogen, and oxygen, with a little azote.

12. *Wax* is found in a number of vegetables; it is procured in abundance from the berries of the Wax Myrtle (*Myrica cerifera*):* it may be likewise obtained from the leaves of many trees: in its pure state it is white. Its specific gravity is ·9662; it melts at 155 degrees: it is dissolved by boiling alcohol; but it is not acted upon by cold alcohol: it is insoluble in water: its properties as a combustible body are well known.

The wax of the vegetable kingdom seems to be precisely of the same nature as that afforded by the bee.†

From the experiments of MM. Gay Lussac and Thenard, it appears that 100 parts of wax consist of

Carbon	-	-	1·784
Oxygen	-	-	5·544
Hydrogen	-	-	12·672

Or otherwise,

Carbon - -	81·784
Oxygen and hydrogen in the proportions necessary to form water - -	6·300
Hydrogen - -	11·916

Which agrees very nearly with 37 proportions of hydrogen, 21 of charcoal, 1 of oxygen.

13. *Resin* is very common in the vegetable kingdom. One of the most usual species is that afforded by the different kinds of fir. When a portion of the bark is removed from a fir-tree in spring, a matter exudes, which is called turpentine; by heating this turpentine gently, a volatile oil rises from it, and a more fixed substance remains: this substance is resin.

The resin of the fir is the substance commonly known by the name of rosin; its properties are well known. Its specific gravity is 1072. It melts readily, burns with a yellow light, throwing off much smoke. Resin is insoluble in water, either hot or cold; but very soluble in alcohol. When a solution of resin in alcohol is mixed with water, the solution becomes milky; the resin is deposited by the stronger attraction of the water for the alcohol.

Resins are obtained from many other species of trees. *Mastich* from the *Pistacia Lentiscus*, *Elemi* from the *Amyris elemifera*, *Copal* from the *Rhus copallinum*, *Sandarach* from the common juniper. Of these resins copal is the most peculiar. It is the most difficultly dissolved in alcohol; and for this purpose must be exposed to that substance in vapor; or the alcohol employed must hold camphor in solution. According to Gay Lussac and Thenard,

100 parts of common resin contain

Carbon	-	-	75·944
Oxygen	-	-	13·337
Hydrogen	-	-	10·719

Or of

Carbon - -	75·944
Oxygen and hydrogen in the proportions necessary to form water	15·156
Hydrogen in excess -	8·900

According to the same chemists, 100 parts of copal consist of

Carbon	-	-	76·811
Oxygen	-	-	10·606
Hydrogen	-	-	12·583

Or,

Carbon - -	76·11
Water or its elements	12·052
Hydrogen - -	11·137

From these results, if resin be a definite compound, it may be supposed to consist of 8 proportions of carbon, 12 of hydrogen, and one of oxygen.

Resins are used for a variety of purposes. Tar and pitch principally consist of resin, in a partially decomposed state. Tar is made by the slow combustion of the fir; and pitch by the evaporation of the more volatile parts of tar. Resins are employed as varnishes, and for these purposes are dissolved in alcohol or oils. Copal forms one of the finest. It may be made by boiling it in powder with oil of rosemary, and then adding alcohol to the solution.

14. *Camphor* is produced by distilling the wood of the camphor-tree (*Laurus Camphora*), which grows in Japan. It is a very volatile body, and may be purified by distillation. Camphor is a white, brittle, semi-transparent substance, having a peculiar odor, and a strong acrid taste. It is very slightly soluble in water; more than 100,000 parts of water are required to dissolve one part of camphor. It is very soluble in alcohol; and by adding water in small quantities at a time to the solution of camphor in alcohol, the camphor separates in a crystallized form. It is soluble in nitric acid, and is separated from it by water.

Camphor is very inflammable; it burns with a bright flame, and throws off a great quantity of carbonaceous matter. It forms, in combustion, water, carbonic acid, and a peculiar acid called *camphoric* acid. No accurate analysis has been made of camphor, but it seems to approach to the resins in its composition; and consists of carbon, hydrogen, and oxygen.

Camphor exists in other plants besides the *Laurus Camphora*. It is procured from species of the Laurus growing in Sumatra, Borneo, and other of the East Indian isles. It has been obtained from Thyme (*Thymus Serpyllum*), Marjorum (*Origanum Majorana*), ginger tree (*Amomum Zingiber*), sage (*Salvia officinalis*). Many volatile oils yield camphor by being merely exposed to the air.

An artificial substance very similar to camphor has been formed by M. Kind, by saturating oil of

* It is also procured from the berries of the cinnamon tree (Laurus Cinnamomum.) The products of this tree are remarkable: its wood is colorless, insipid, and inodorous; its bark, as is well known, contains the oil which bears its name; its leaves, an oil similar to that of cloves; its berries, wax, as above mentioned; and its roots camphor.—J. D.

† According to the recent analysis of bees' wax and of vegetable wax by Oppermann, they differ in the proportions of their elements.—J. D.

turpentine with muriatic acid gas (the gaseous substance procured from common salt by the action of sulphuric acid.) The camphor procured in well-conducted experiments amounts to half of the oil of turpentine used. It agrees with common camphor in most of its sensible properties; but differs materially in its chemical qualities and composition. It is not soluble without decomposition in nitric acid. From the experiments of Gehlen it appears to consist of the elements of oil of turpentine, carbon, hydrogen, and oxygen, united to the elements of muriatic gas, chlorine, and hydrogen.

From the analogy of artificial to natural camphor, it does not appear improbable that natural camphor may be a secondary vegetable compound, consisting of camphoric acid and volatile oil. Camphor is used medicinally, but it has no other application.*

15. *Fixed oil* is obtained by expression from seeds and fruits; the olive, the almond, linseed, and rape-seed, afford the most common vegetable fixed oils. The properties of fixed oils are well known. Their specific gravity is less than that of water; that of olive and of rape-seed oil is ·913; that of linseed and almond oil ·932; that of palm oil ·968; that of walnut and beech-mast oil ·923. Many of the fixed oils congeal at a lower temperature than that at which water freezes. They all require for their evaporation a higher temperature than that at which water boils.† The products of the combustion of oil are water and carbonic acid gas.

From the experiments of Gay Lussac and Thenard, it appears that olive oil contains, in 100 parts.

Carbon	-	-	77·213
Oxygen	-	-	9·427
Hydrogen	-	-	13·360

This estimation is a near approximation to 11 proportions of carbon, 20 hydrogen and 1 oxygen.

The following is a list of fixed oils, and of the trees that afford them.

Olive oil, from the Olive tree (*Olea Europea*), Linseed oil, from the common and perennial Flax (*Linum usitatissimum et perenne*), Nut oil, from the Hazel nut (*Corylus Avellana*), Walnut (*Juglans regia*), Hemp oil, from the Hemp (*Cannabis sativa*), Almond oil, from the sweet Almond (*Amygdalus communis*), Beech oil, from the common Beech (*Fagus sylvatica*), Rape-seed oil, from the Rapes (*Brassica Napus et campestris*), Poppy oil, from the Poppy (*Papaver somniferum*), oil of Sesamum, from the sesamum (*Sesamum orientale*), Cucumber oil, from the gourds (*Cucurbita Pepo et Melopepo*), oil of Mustard (*Sinapos nigra et arvensis*), oil of Sunflower, from the annual and perennial Sunflower (*Helianthus annuus et perennis*), Castor oil, from the Palma Christi (*Ricinus communis*), Tobacco-seed oil, from the Tobacco (*Nicotiana Tabacum et rustica*), Plum kernel oil, from the Plum tree (*Prunus domestica*), Grape-seed oil, from the Vine (*Vitis vinifera*), Butter of cacoa, from the Cacoa tree (*Theobroma Cacao*), Laurel oil, from the sweet Bay tree (*Laurus nobilis*).

The fixed oils are very nutritive substances; they are of great importance in their applications to the purposes of life. Fixed oil, in combination with soda, forms the finest kind of hard soap. The fixed oils are used extensively in the mechanical arts, and for the preparation of pigments and varnishes.

16. *Volatile oil*, likewise called *essential oil*, differs from fixed oil, in being capable of evaporation by a much lower degree of heat, in being soluble in alcohol, and in possessing a very slight degree of solubility in water.

There is a great number of volatile oils, distinguished by their smell, their taste, their specific gravity and other sensible qualities. A strong and peculiar odor may, however, be considered as the great characteristic of each species: the volatile oils inflame with more facility than the fixed oils, and afford, by their combustion, different proportions of the same substances, water, carbonic acid, and carbon.

The following specific gravities of different volatile oils, were ascertained by Dr. Lewis:

Oil of Sassafras	1094	Oil of Tansy	946
" Cinnamon	1035	" Caraway	940
" Cloves	1034	" Origanum	940
" Fennel	997	" Spike	936
" Dill	994	" Rosemary	934
" Penny Royal	978	" Juniper	911
" Cumin	975	" Oranges	888
" Mint	975	" Turpentine	792
" Nutmegs	948		

The peculiar odours of plants seem, in almost all cases, to depend upon the peculiar volatile oils they contain. All the perfumed distilled waters owe their peculiar properties to the volatile oils they hold in solution. By collecting the aromatic oils, the fragrance of flowers, so fugitive in the common course of nature, is as it were embodied and made permanent.

It cannot be doubted that the volatile oils consist of carbon, hydrogen, and oxygen; but no accurate experiments have as yet been made on the proportions in which these elements are combined.

The volatile oils have never been used as articles of food; many of them are employed in the arts, in the manufacture of pigments and varnishes; but their most extensive application is as perfumes.

17. *Woody fibre* is procured from wood, bark, leaves or flowers of trees, by exposing them to the repeated action of boiling water and boiling alcohol. It is the insoluble matter that remains, and is the basis of the solid organized parts of plants. There are as many varieties of woody fibre as there are plants and organs of plants; but they are all distinguished by their fibrous texture, and their insolubility.

Woody fibre burns with a yellow flame, and produces water and carbonic acid in burning. When it is distilled in close vessels, it yields a considerable residuum of charcoal. It is from woody fibre, indeed, that charcoal is procured for the purposes of life.

The following table contains the results of experiments made by Mr. Mushet, on the quantity of charcoal afforded by different wood:—

* From the researches of Dumas, it would appear that camphor is an oxide of camphene, itself a compound of carbon and hydrogen.—J. D.

† From the researches of Chevreul and Le Canu, it would appear that the fixed oils consist of two principles,—a fluid principle oleine, and a solid one margarine,—the proportions of which vary in different instances.—J. D.

100 parts of Lignum Vitæ	-	26·8 of charcoal
Mahogany	-	25·4
Laburnum	-	24·5
Chestnut	-	23·2
Oak	-	22·6
American black Beech	-	21·4
Walnut	-	20·6
Holly	-	19·9
Beech	-	19·9
American Maple	-	19·9
Elm	-	19·5
Norway Pine	-	19·2
Sallow	-	18·4
Ash	-	17·9
Birch	-	17·4
Scottish Fir	-	16·4

MM. Gay Lussac and Thenard have concluded, from their experiments on the wood of the oak and the beech, that 100 parts of the first contain:—

Of Carbon	52·53
Oxygen	41·78
Hydrogen	5·69

and 100 parts of the second—

Of Carbon	51·45
Oxygen	42·73
Hydrogen	5·82

Supposing woody fibre to be a definitive compound, these estimations lead to the conclusion, that it consists of 5 proportions of carbon, 3 of oxygen, and 6 of hydrogen; or 57 carbon, 45 oxygen, and 6 hydrogen.

It will be unnecessary to speak of the applications of woody fibre. The different uses of the woods, cotton, linen, the barks of trees, are sufficiently known. Woody fibre appears to be an indigestible substance. *

18. The acids found in the vegetable kingdom are numerous; the true vegetable acids which exist ready formed in the juices or organs of plants, are the *oxalic*, *citric*, *tartaric*, *benzoic*, *acetic*, *meconic*, *malic*, *gallic*, and *prussic* acids.

All these acids, except the acetic, malic, and prussic acids, are white crystallized bodies. The acetic, malic, and prussic acids have been obtained only in the fluid state; they are all more or less soluble in water; all have a sour taste except the gallic and prussic acids; of which the first has an astringent taste, and the latter a taste like that of bitter almonds. The meconic acid exists in opium.

The oxalic acid exists, uncombined, in the liquor which exudes from the Chich pea (*Cicer arietinum,*) and may be procured from wood Sorrel (*Oxalis Acetosella,*) common sorrel, and other species of Rumex: and from the *Geranium acidum.* Oxalic acid is easily discovered and distinguished from other acids by its property of decomposing all calcareous salts, and forming with lime a salt insoluble in water; and by its crystallizing in four-sided prisms.

The citric acid is the peculiar acid existing in the juice of lemons and oranges. It may likewise be obtained from the cranberry, whortleberry, and hip.

* By trituration and fermentation, and the heat of the oven, woody fibre may be converted into a kind of bread; by the action of strong sulphuric acid on it, it may be changed into a kind of gum, and this gum, by boiling, may be transformed into sugar: and as it is possible that similar changes may be effected in it in the alimentary canal of animals, it may not be entirely indigestible.—J. D.

Citric acid is distinguished by its forming a salt insoluble in water with lime; but decomposable by the mineral acids.

The tartaric acid may be obtained from the juice of mulberries and grapes; and likewise from the pulp of the tamarind. It is characterized by its property of forming a difficultly soluble salt with potassa, and an insoluble salt decomposable by the mineral acids with lime.

Benzoic acid may be procured from several resinous substances by distillation; from benzoin, storax, and balsam of Tolu. It is distinguished from the other acids by its aromatic odour, and by its extreme volatility.

Malic acid may be obtained from the juice of apples, barberries, plums, elderberries, currants, strawberries, and raspberries. It forms a soluble salt with lime; and is easily distinguished by this test from the acids already named.

Acetic acid, or vinegar, may be obtained from the sap of different trees. It is distinguished from malic acid by its peculiar odor; and from the other vegetable acids by forming soluble salts with the alkalies and earths.

Gallic acid may be obtained by gently and gradually heating powdered gall-nuts, and receiving the volatile matter in a cool vessel. A number of white crystals will appear, which are distinguished by their property of rendering solutions of iron deep purple.

The vegetable prussic acid is procured by distilling laurel leaves, or the kernels of the peach, and cherry, or bitter almonds. It is characterized by its property of forming a bluish green precipitate, when a little alkali is added to it, and it is poured into solutions containing iron. It is very analogous in its properties to the prussic acid obtained from animal substances; or by passing ammonia over heated charcoal; but this last body forms, with the red oxide of iron, the deep bright blue substance called Prussian blue.

Some other vegetable acids have been found in the products of plants; the morolyxic acid in a saline exudation from the white mulberry tree, and the kinic acid in a salt afforded by Peruvian bark; but these two bodies have as yet been discovered in no other cases. The igasuric acid is so named by its discoverers, MM. Pelletier and Caventou: and the boletic, nanceic, fungic, and ellagic acids, have been described by M. Braconnot; but their properties are too little interesting to the agriculturist to insert a description in this place. The phosphoric acid is found free in the onion; and the phosphoric, sulphuric, muriatic, and nitric acids, exist in many saline compounds in the vegetable kingdom; but they cannot with propriety be considered as vegetable products. Other acids are produced during the combustion of vegetable compounds, or by the action of nitric acid upon them; they are the camphoric acid, the mucous or saclactic acid, and the suberic acid; the first of which is procured from camphor; the second from gum or mucilage; and the third from cork, by the action of nitric acid.

From the experiments that have been made upon the vegetable acids, it appears that all of them, except the prussic acid, are constituted by different proportions of carbon, hydrogen, and oxygen: the prussic acid consists of carbon, azote, and hydrogen, with a little oxygen. The gallic acid contains more carbon than any of the other vegetable acids.

The following estimates of the composition of some of the vegetable acids have been made by Gay Lussac and Thenard:—

100 parts of oxalic acid contain:

Carbon	- -	26·566
Hydrogen	- -	2·745
Oxygen	- -	70·689

100 parts of tartaric acid contain:

Carbon	- -	24·050
Hydrogen	- -	6·629
Oxygen	- -	69·321

Ditto citric acid:

Carbon	- -	33·811
Hydrogen	- -	6·330
Oxygen	- -	59·859

100 parts of acetic acid:

Carbon	- -	50·224
Hydrogen	- -	5·629
Oxygen	- -	44·147

Ditto mucous or saclactic acid:

Carbon	- -	33·69
Hydrogen	- -	3·62
Oxygen	- -	62·69

These estimations agree nearly with the following definite proportions. In oxalic acid, 7 proportions of carbon, 8 of hydrogen, and 15 oxygen; in tartaric acid, 8 carbon, 28 hydrogen, 18 oxygen; in citric acid, 3 carbon, 6 hydrogen, 4 oxygen; in acetic acid, 18 carbon, 22 hydrogen, 12 oxygen; in mucous acid, 6 carbon, 7 hydrogen, 8 oxygen.

The applications of the vegetable acids are well known. The acetic and citric acids are extensively used. The agreeable taste and wholesomeness of various vegetable substances used as food, materially depend upon the vegetable acid they contain.

19. It is uncertain whether ammonia or the volatile alkali exists ready formed in plants: but it is evolved from many of them by the action of lime or fixed alkali, assisted by a gentle heat; though it may be always imagined to be generated during the process by the combination of azote and carbon. The ingenious researches of M. Serturner, followed by those of other chemists, have made us acquainted with the alkaline properties of several compound vegetable substances, which were not suspected to belong to this class of bodies, such as morphina, strychnina, brucina, picrotoxina, delphina*; these compounds, which are found respectively in opium, nux vomica, Brucea anti-dysenterica, cocculus indicus, and Delphinium Staphisagria, agree with alkalies in their effects upon vegetable colors, and in combining with acids, into peculiar neutrosaline compounds. They form the narcotic or poisonous principles of the plants in which they are found, and probably many more of them will be discovered. They are not very interesting to the agriculturist, except in this point of view, *that possibly many noxious vegetable substances may be rendered useful as the food of cattle*, by extracting their noxious principles by means of acids; and this is a subject well worthy of experimental investigation.

Fixed alkali may be obtained in aqueous solution from most plants by burning them, and treating the ashes with quick-lime and water. The vegetable alkali, or potassa, is the common alkali in the vegetable kingdom. This substance, in its pure state, is white and semi-transparent, requiring a strong heat for its fusion, and possessed of a highly caustic taste. In the matter usually called pure potassa by chemists, it exists, combined with water: and in that commonly called pearl-ashes, or pot-ashes in commerce, it is combined with a small quantity of carbonic acid. Potassa in its uncombined state, as has been mentioned, consists of the highly inflammable metal potassium and oxygen, one proportion of each.

Soda, or the mineral alkali, is found in some plants that grow near the sea; and is obtained combined with water, or carbonic acid in the same manner as potassa; and consists, as has been stated, of one proportion of sodium, and two proportions of oxygen. In its properties it is very similar to potassa; but it may be easily distinguished from it by this character; it forms a hard soap with oil: potassa forms a soft soap.

Pearl ashes, and barilla and kelp, or the impure soda obtained from the ashes of marine plants, are very valuable in commerce, principally on account of their uses in the manufacture of glass and soap. Glass is made from fixed alkali, flint, and certain metallic substances.

To know whether a vegetable yields alkali, it should be burnt, and the ashes washed with a small quantity of water. If the water, after being for some time exposed to the air, reddens paper tinged with turmeric, or renders vegetable blues green, it contains alkali.

To ascertain the relative quantities of pot-ashes afforded by different plants, equal weights of them should be burnt: the ashes washed in twice their volume of water: the washings should be passed through blotting paper, and evaporated to dryness. The relative weights of the salt obtained will indicate very nearly the relative quantities of alkali they contain.

The value of marine plants in producing soda may be estimated in the same manner, with sufficient correctness for all commercial purposes.

Herbs, in general, furnish four or five times, and shrubs two or three times, as much pot-ashes as trees. The leaves produce more than the branches, and the branches more than the trunk. Vegetables burnt in a green state produce more ashes than in a dry state.

The following table* contains a statement of the quantity of pot-ashes afforded by some common trees and plants:—

10,000 parts of	Oak	- -	15
	Elm	- -	39
	Beech	- -	12
	Vine	- -	55
	Poplar	- -	7
	Thistle	- -	53
	Fern	- -	62
	Cow Thistle	-	196
	Wormwood	-	730
	Vetches	- -	275
	Beans	- -	200
	Fumitory	- -	760

The earths found in plants are four; silica or the earth of flints, alumina or pure clay, lime, and mag-

* Many more have since been discovered, as codeia, narceia, aricina, &c. All the compounds of this class are composed of carbon, hydrogen, azote, and oxygen. —J. D.

* It is founded upon the experiments of Kirwan, Vauquelin, and Pertuis.

nesia. They are procured by incineration. The lime is usually combined with carbonic acid. This substance and silica, are much more common in the vegetable kingdom than magnesia, and magnesia more common than alumina. The earths form a principal part of the matter insoluble in water, afforded by the ashes of plants. The silica is known by not being dissolved by acids; the calcareous earth, unless the ashes have been very intensely ignited, dissolves with effervescence in muriatic acid. Magnesia forms a soluble and crystallizable salt, and lime a difficultly soluble one with sulphuric acid. Alumina is distinguished from the other earths by being acted upon very slowly by acids; and in forming salts very soluble in water, and difficult of crystallization with them.

The earths appear to be compounds of the peculiar metals before mentioned, and oxygen, one proportion of each.

The earths afforded by plants, are applied to no uses of common life; and there are few cases in which the knowledge of their nature can be of importance, or afford interest to the farmer.

The only *metallic oxides* found in plants, are those of iron and manganesum: they are detected in the ashes of plants; but in very minute quantities only. When the ashes of plants are reddish brown, they abound in oxides of iron. When black or purple, in oxide of manganesum; when these colours are mixed, they contain both substances.

The saline compounds contained in plants, or afforded by their incineration, are very various. The sulphuric acid combined with potassa, or sulphate of potassa, is one of the most usual. Common salt is likewise very often found in the ashes of plants; likewise phosphate of lime, which is insoluble in water, but soluble in muriatic acid. Compounds of the nitric, muriatic, sulphuric, and phosphoric acids, with alkalies and earths, exist in the sap of many plants, or are afforded by their evaporation and incineration. The salts of potassa are distinguished from those of soda by their producing a precipitate in solutions of platina: those of lime are characterized by the cloudiness they occasion in solutions containing oxalic acid; those of magnesia, by being rendered cloudy by solutions of ammonia. Sulphuric acid is detected in salts by the dense white precipitate it forms in solutions of baryta. Muriatic acid by the cloudiness it communicates to solution of nitrate of silver; and when salts contain nitric acid, they produce scintillations by being thrown upon burning coals.

As no applications have been made of any of the neutral salts or analogous compounds found in plants, in a separate state, it will be useless to describe them individually. The following tables are given from M. Th. de Saussure's Researches on vegetation, and contain results obtained by that philosopher. They exhibit the quantities of soluble salts, metallic oxides, and earths afforded by the ashes of different plants.

Besides the principles, the nature of which has been just discussed, others have been described by chemists as belonging to the vegetable kingdom: thus a substance, somewhat analogous to the muscular fibre of animals, has been detected by Vauquelin in the papaw; and a matter similar to animal gelatine, by Braconnot, in the mushroom; ulmin * and emetine, sarcocol, nicotine, olivile, asparagine, inulin, and other bodies, are generally described in systematic writers on chemistry as specific compounds; but it is likely that few of these bodies will retain their places as definite combinations: their existence, likewise, is extremely limited, and in this place it would be improper to dwell upon peculiarities; my object being to offer such general views of the constitution of vegetables as may be of use to the agriculturist. It is probable, from the taste of sarcocol, that it is gum combined with a little sugar. Inulin is so analogous to starch, that it may be a variety of that principle. If slight differences in chemical and physical properties be considered as sufficient to establish a difference in the species of vegetable substances, the catalogue of them might be enlarged to almost any extent. No two compounds procured from different vegetables are precisely alike; and there are even differences in the qualities of the same compound, according to the time in which it has been collected, and the manner in which it has been prepared. The great use of classification in science is to assist the memory, and it ought to be founded upon the similarity of properties which are distinct, characteristic, and invariable.

The analysis of any substance, containing mixtures of the different vegetable principles, may be made, in such a manner as is necessary for the views of the agriculturist, with facility. A given quantity, say 200 grains, of the substance should be powdered, made into a paste or mass, with a small quantity of water, and kneaded in the hands, or rubbed in a mortar for some time under cold water: if it contain much gluten, that principle will separate in a coherent mass. After this process, whether it has afforded gluten or not, it should be kept in contact with half a pint of cold water for three or four hours, being occasionally rubbed or agitated; the solid matter should be separated from the fluid by means of blotting paper. The fluid should be gradually heated; if any flakes appear, they are to be separated by the same means as the solid matter in the last process, *i. e.* by filtration. The fluid is then to be evaporated to dryness. The matter obtained is to be examined by applying moist paper, tinged with red cabbage juice, or violet juice, to it; if the paper become red, it contains acid matter; if it become green, alkaline matter; and the nature of the acid or alkaline matter may be known by applying the tests already described. If the solid matter be sweet to the taste, it must be supposed to contain sugar; if bitterish, bitter principle, or extract; if astringent, tannin: and if it be nearly insipid, it must be principally gum or mucilage. To separate gum or mucilage from the other principles, alcohol must be boiled upon the solid matter, which will dissolve the sugar and the extract, and leave the mucilage; the weight of which may be ascertained.

---

* Ulmin, in relation to agricultural chemistry, would appear, from the researches of M. Boullay, to be a substance of some importance. It is of a dark colour, almost black; nearly insoluble in water, having some of the properties of an acid; readily combining with alkalies and the alkaline earths, with which it forms soluble compounds. It is an ingredient of peat and vegetable mould, and may be considered as a natural manure.—J. D.

To separate sugar and extract, the alcohol must be evaporated till crystals begin to fall down, which are sugar; but they will generally be coloured by some extract, and can only be purified by repeated solutions in alcohol. Extract may be separated from sugar by dissolving the solid, obtained by evaporation from alcohol, in a small quantity of water, and boiling it for a long while in contact with the air. The extract will gradually fall down in the form of an insoluble powder, and the sugar will remain in solution.

If tannin exist in the first solution made by cold water, its separation is easily effected by the process before described. The solution of isinglass must be gradually added, to prevent the existence of an excess of animal jelly in the solution, which might be mistaken for mucilage.

When the vegetable substance, the subject of experiment, will afford no more principles to cold water, it must be exposed to boiling water. This will unite to starch, if there be any, and may likewise take up more sugar, extract, and tannin, provided they be intimately combined with the other principles of the compound.

The mode of separating starch is similar to that of separating mucilage.

If after the action of hot water any thing remain, the action of boiling alcohol is then to be tried. This will dissolve resinous matter; the quantity of which may be known by evaporating the alcohol.

The last agent that may be applied is ether, which dissolves elastic gum, though the application is scarcely ever necessary; for if this principle be present, it may be easily detected by its peculiar qualities.

If any fixed oil or wax exist in the vegetable substance, it will separate during the process of boiling in water, and may be collected. Any substance not acted upon by water, alcohol, or ether, must be regarded as woody fibre.

If volatile oils exist in any vegetable substances, it is evident they may be procured, and their quantity ascertained, by distillation.

When the quantity of fixed saline, alkaline, metallic, or earthy matter in any vegetable compound is to be ascertained, the compound must be decomposed by heat, by exposing it, if a fixed substance, in a crucible, to a long continued red heat; and if a volatile substance, by passing it through an ignited porcelain tube. The nature of the matter so produced may be learned by applying the tests mentioned in Lecture IV.

The only analyses in which the agricultural chemist can often wish to occupy himself, are those of substances containing principally starch, sugar, gluten, oils, mucilage, albumen, and tannin.

The two following statements will afford an idea of the manner in which the results of experiments may be arranged.

The first is a statement of the composition of ripe peas, deduced from experiments made by Einhof; the second is of the products afforded by oak bark, deduced from experiments conducted by myself.

	Parts.
3840 parts of ripe peas afford of starch -	1265
Fibrous matter analogous to starch, with the coats of the peas -	840
A substance analogous to gluten	
Mucilage - - - -	249
Saccharine matter - - -	81
Albumen - - - -	66
Volatile matter - - -	540

1000 parts of dry oak bark, from a small tree deprived of epidermis, contain,

Of Woody Fibre - - -	876
Tannin - - - -	57
Extract - - - -	31
Mucilage - - - -	18
Matter rendered insoluble during evaporation, probably a mixture of albumen and extract -	9
Loss, partly saline matter - -	29

To ascertain the primary elements of the different vegetable principles, and the proportions in which they are combined, different methods of analysis have been adopted. The most simple are their decomposition by heat, or their formation into new products by combustion.

When any vegetable principle is acted on by a strong red heat, its elements become newly arranged. Such of them as are volatile are expelled in the gaseous form; and are either condensed as fluids, or remain permanently elastic. The fixed remainder is either carbonaceous, earthy, saline, alkaline, or metallic matter.

To make correct experiments on the decomposition of vegetable substances by heat, requires a complicated apparatus, much time and labor, and all the resources of the philosophical chemist; but such results as are useful to the agriculturist may be easily obtained. The apparatus necessary, is a green glass retort, attached by cement to a receiver, connected with a tube passing under an inverted jar of known capacity, filled with water.* A given weight of the substance is to be heated to redness, in the retort over a charcoal fire; the receiver is to be kept cool, and the process continued as long as any elastic matter is generated. The condensible fluids will collect in the receiver, and the fixed residuum will be found in the retort. The fluid products of the distillation of vegetable substances are principally water, with some acetous and mucous acids, and empyreumatic oil, or tar, and in some cases ammonia. The gases are carbonic acid gas, carbonic oxide, and carburetted hydrogen; sometimes with olefiant gas, and hydrogen; and sometimes, but more rarely, with azote. Carbonic acid is the only one of those gases rapidly absorbed by water; the rest are inflammable; olefiant gas burns with a bright white light; carburetted hydrogen with a light like wax; carbonic oxide with a feeble blue flame. The properties of hydrogen and azote have been described in the last lecture. The specific gravity of carbonic acid gas, is to that of air as 20.7, to 13.7, and it consists of one proportion of carbon 11.4, and two of oxygen 30. The specific gravity of gaseous oxide of carbon, is, taking the same standard, 13.2, and it consists of one proportion of carbon, and one of oxygen.

* See Fig. 14.

The specific gravities of carburetted hydrogen and olefiant gas, are respectively 8 and 13; both contain four proportions of hydrogen; the first contains one proportion, the second two proportions of carbon.

If the weight of the carbonaceous residuum be added to the weight of the fluids condensed in the receiver, and they be subtracted from the whole weight of the substance, the remainder will be the weight of the gaseous matter.

The acetous and mucous acids, and the ammonia formed, are usually in very small quantities; and by comparing the proportions of water and charcoal with the quantity of the gases, taking into account their qualities, a general idea may be formed of the composition of the substance. The proportions of the elements in the greater number of the vegetable substances which can be used as food, have been already ascertained by philosophical chemists, and have been stated in the preceding pages; the analysis by distillation, may, however, in some cases, be useful in estimating the powers of manures, in a manner that will be explained in a future lecture.

The statements of the composition of vegetable substances, quoted from MM. Gay Lussac and Thenard, were obtained by these philosophers by exposing the substances to the action of heated chlorate of potassa; a body that consists of potassium, chlorine, and oxygen; and which afforded oxygen to the carbon and the hydrogen. Their experiments were made in a peculiar apparatus, and required great caution, and were of a very delicate nature. It will not therefore be necessary to enter upon any details of them.

It is evident from the whole tenor of the statements which have been made, that the most essential vegetable substances consist of hydrogen, carbon, and oxygen in different proportions, generally alone, but in some few cases combined with azote. The acids, alkalies, earths, metallic oxides, and saline compounds, though necessary in the vegetable economy, must be considered as of less importance, particularly in their relation to agriculture, than the other principles; and as it appears from M. de Saussure's table, and from other experiments, they differ in the same species of vegetable when it is raised on different soils.

MM. Gay Lussac and Thenard have deduced three propositions, which they have called *laws*, from their experiments on vegetable substances. *The first* is, "That a vegetable substance is always acid whenever the oxygen it contains is to the hydrogen in a greater proportion than in water."

The third, "That a vegetable substance is neither acid nor resinous, but is either saccharine or mucilaginous, or analogous to woody fibre or starch, whenever the oxygen and hydrogen in it are in the same proportions as in water."

The second, "That a vegetable substance is always resinous, or oily or spirituous, whenever it contains oxygen in a smaller proportion to the hydrogen than exists in water."

New experiments upon other vegetable substances, besides those examined by MM. Gay Lussac and Thenard, are required before these interesting conclusions can be fully admitted. Their researches establish, however, the close analogy between several vegetable compounds differing in their sensible qualities, and combined with those of other chemists, offer simple explanations of several processes in nature and art, by which different vegetable substances are converted into each other, or changed into new compounds.

Gum and sugar, excluding the different proportions of water they may contain, afford nearly the same elements by analysis; and starch differs from them only in containing a little more carbon. The peculiar properties of gum and sugar must depend chiefly upon the different arrangement, or degree of condensation of their elements; and it would be natural to conceive, from the composition of these bodies, as well as that of starch, that all three would be easily convertible one into the other; which is actually the case.

At the time of the ripening of corn, the saccharine matter in the grain, and that carried from the sap vessels into the grain, become coagulated, probably simply by losing water, and form starch. And in the process of malting, the converse change occurs. The starch of grain is converted into sugar. As there is a little absorption of oxygen, and a formation of carbonic acid in this case, it is likely that the starch loses a little carbon, which combines with the oxygen to form carbonic acid; and probably the oxygen tends to acidify the gluten of the grain, and thus breaks down the texture of the starch; gives a new arrangement to its elements, and renders it soluble in water.

Mr. Cruikshank, by exposing syrup to a substance named phosphuret of lime, which has great tendency to decompose water, converted a part of the sugar into a matter analogous to mucilage. And M. Kirchhoff, recently, has converted starch into sugar by a very simple process, that of boiling in very diluted sulphuric acid.* The proportions are 100 parts of starch, 400 parts of water, and 1 part of the sulphuric acid by weight. This mixture is to be kept boiling for 40 hours; the loss of water by evaporation being supplied by new quantities. The acid is to be neutralized by lime; and the sugar crystallized by cooling. This experiment has been tried with success by many persons. Sir C. Tuthill, from a pound and a half of potato starch, procured a pound and a quarter of crystalline, brown sugar; which he conceives possessed properties intermediate between cane-sugar, and grape-sugar.

It is probable, from the experiments of M. Theodore de Saussure, that conversion of starch into sugar, in this experiment, is effected merely by its combination with water; for his experiments prove that the acid is not decomposed, and that no elastic matter is set free, and that the sugar weighs more than the starch from which it is formed: probably the color of the sugar, is owing to the disengagement or new combination of a little carbon, the slight excess of which, as has been just stated, constitutes the only difference (independent of the different quantities of water they may contain) perceptible by analysis between sugar and starch.

M. Bouillon la Grange, by slightly roasting starch, has rendered it soluble in cold water; and the solution evaporated afforded a substance, having the characters of mucilage. And by experiments similar to those of M. Kirchhoff, M. Braconnot has lately shown that saccharine and mucilaginous substances may be procured from various forms of woody fibre; and I have seen specimens of soft sugar made from linen rags.

Gluten and albumen differ from the other vegetable products, principally by containing azote. When gluten is kept long in water, it undergoes fermentation; ammonia (which contains its azote) is given off with acetic acid; and a fatty matter and a substance analogous to woody fibre remain.

Extract, tannin, and gallic acid, when their solutions are long exposed to air, deposite a matter similar to woody fibre; and the solid substances are rendered analogous to woody fibre, by slight roasting; and in these cases it is probable that part of their oxygen and hydrogen is separated as water.

All the other vegetable principles differ from the vegetable acids in containing more hydrogen and carbon, or less oxygen; many of them, therefore, are easily converted into vegetable acids by a mere subtraction of some proportions of hydrogen. The vegetable acids, for the most part, are convertible into each other by easy processes. The oxalic contains most oxygen; the acetic the least: and this last substance is easily formed by the distillation of other vegetable substances, or by the action of the atmosphere on such of them as are soluble in water; probably by the mere combination of oxygen with hydrogen and carbon, or in some cases by the subtraction of a portion of hydrogen.

Alcohol, or spirits of wine, has been often mentioned in the course of these lectures. This substance was not described amongst the vegetable principles, because it has never been found ready formed in the organs of plants. It is procured by a change in the principles of saccharine matter, in a process called vinous fermentation.

The expressed juice of the grape contains sugar, mucilage, gluten, and some saline matter, principally composed of tartaric acid: when this juice, or *must*, as it is commonly called, is exposed to the temperature of about 70°, the fermentation begins; it becomes thick and turbid; its temperature increases, and carbonic acid gas is disengaged in abundance. In a few days the fermentation ceases; the solid matter that rendered the juice turbid falls to the bottom, and it clears; the sweet taste of the fluid is in great measure destroyed, and it is become spirituous.

Fabroni has shown that the gluten in must is essential to fermentation; and that chemist has made saccharine matter ferment, by adding to its solution in water, common vegetable gluten and tartaric acid. Gay Lussac has demonstrated that must will not ferment when freed from air by boiling, and placed out of the contact of oxygen; but that fermentation begins as soon as it is exposed to the oxygen of air, a little of that principle being absorbed; and that it then continues independent of the presence of the atmosphere.*

* Some kinds of vinegar, especially those made from sugar, are converted into an insoluble substance resembling lignin, or the principle of the woody fibre, by exposure to the atmosphere. This I have witnessed in many instances; the new substance which is like lignin, forms on the surface of the vinegar, and leaves a dense strong crust, occasionally in appearance not unlike the buffy coat of blood.—J. D.

* Farther experiments appear to be required on this subject. I have not found the fermentation of must prevented either by immersing in it phosphorus in a close vessel, or by agitating it, in contact with a minute portion of nitrous gas.—J. D.

In the manufacture of ale and porter, the sugar formed during the germination of barley is made to ferment by dissolving it in water with a little yeast, which contains gluten in the state proper for producing fermentation, and exposing it to the requisite temperature; carbonic acid gas is given off as in the fermentation of must, and the liquor gradually becomes spirituous.

Similar phenomena occur in the fermentation of the sugar in the juice of apples and other ripe fruits. It appears that fermentation depends entirely upon a new arrangement of the elements of sugar; part of the carbon uniting to oxygen to form carbonic acid, and the remaining carbon, hydrogen, and oxygen combining as alcohol; and the use of the gluten or yeast, and the primary exposure to air, seems to be to occasion the formation of a certain quantity of carbonic acid; and this change being once produced is continued; its agency may be compared to that of a spark in producing the inflammation of gunpowder; the increase of temperature occasioned by the formation of one quantity of carbonic acid occasions the combination of the elements of another quantity.

From the experiments of M. Theodore de Saussure it appears that alcohol is composed of 100 parts of olefiant (or percarburetted hydrogen gas), and of 63.58 water, or oxygen and hydrogen in the proportions necessary to form water.

Alcohol, in its purest known form, is a highly inflammable liquid, of specific gravity 796, at the temperature of 60°; it boils at about 170° Fahrenheit. This alcohol is obtained by repeated distillation of the strongest common spirit from the salt called by chemists muriate of lime, it having been previously heated red hot.

The strongest alcohol obtained by the distillation of spirit without salts has seldom a less specific gravity than 825 at 60°; and it contains, according to Lowitz's experiments, 89 parts of the alcohol of 796, and 11 parts of water. The spirit established as *proof spirit* by act of parliament passed in 1762 ought to have the specific gravity of 916; and this contains nearly equal weights of pure alcohol and water.

The alcohol in fermented liquors is in combination with water, coloring matter, sugar, mucilage, and the vegetable acids. It has been often doubted whether it can be procured by any other process than distillation; and some persons have even supposed that it *is formed* by distillation. The experiments of Mr. Brande are conclusive against both these opinions. That gentleman has shown that the coloring and acid matter in wines may be, for the most part, separated in a solid form by the action of a solution of sugar of lead (acetate of lead,) and that the alcohol may be then obtained by abstracting the water by means of hydrate of potassa or muriate of lime, without artificial heat.

The intoxicating powers of fermented liquors depend on the alcohol that they contain; but their action on the stomach is modified by the acid, saccharine, or mucilaginous substances they hold in solution. Alcohol probably acts with most efficacy when it is most loosely combined; and its energy seems to be impaired by union with large quantities of water, or with sugar or acid, or extractive matter.

The table in the following page contains the results of Mr. Brande's experiments on the quantity of alcohol of 825 at 60°, in different fermented liquors.

The spirits distilled from different fermented liquors differ in their flavor: for peculiar odorous matter, or volatile oils, rise in most cases with the alcohol. The spirit from malt usually has an empyreumatic taste like that of the oil, formed by the distillation of vegetable substances. The best brandies seem to owe their flavor to a peculiar oily matter, formed probably by the action of the tartaric acid on alcohol; and rum derives its characteristic taste from a principle in the sugar cane. All the common spirits may, I find, be deprived of their peculiar flavour by repeatedly digesting them with a mixture of well-burnt charcoal and quicklime; they then afford pure alcohol by distillation. The cognac brandies, I find, contain vegetable prussic acid, and their flavour may be imitated by adding to a solution of alcohol in water of the same strength, a few drops of the ethereal oil of wine produced during the formation of ether,* and a similar quantity of vegetable prussic acid procured from laurel leaves or any bitter kernels.

I have mentioned *ether* in the course of this Lecture; this substance is procured from alcohol by distilling a mixture of equal parts of alcohol and sulphuric acid. It is the lightest known liquid substance, being of specific gravity 632 at 60°. It is very volatile and rises in vapor, even by the heat of the body. It is highly inflammable. In the formation of ether it is most probable, from the experiments of M. de Saussure, that the elements of water merely are separated from the alcohol by the sulphuric acid, and that ether differs from alcohol in containing a larger proportion of carbon and hydrogen. Like alcohol, it possesses intoxicating powers.

A number of the changes taking place in the vegetable principles depend upon the separation of oxygen and hydrogen as water from the compound; but there is one of very great importance, in which a new combination of the elements of water is the principal operation. This is in the manufacture of bread. When any kind of flour, which consists principally of starch, is made into a paste with water, and immediately and gradually heated to about 440°, it increases in weight, and is found entirely altered in its properties; it has lost its solubility in water, and its power of being converted into sugar. In this state it is unleavened bread.

When the flour of corn or the starch of potatoes, mixed with boiled potatoes, is made into a paste with water, kept warm, and suffered to remain 30 or 40 hours, it ferments, carbonic acid gas is disengaged from it, and it becomes filled with globules of elastic fluid. In this state it is raised dough, and affords, by baking, leavened bread; but this bread is sour and disagreeable to the taste; and leavened bread for use is made by mixing a little dough, that has fermented, with new dough, and kneading them together, or by kneading the bread with a small quantity of yeast.

In the formation of wheaten bread, more than one quarter of the elements of water combine

* In the process of the distillation of alcohol and sulphuric acid after the ether is procured; by a higher degree of heat, a yellow fluid is produced; which is the substance in question. It has a fragrant smell and an agreeable taste.

with the flour; more water is consolidated in the formation of bread from barley, and still more in that from oats; but the gluten in wheat, being in much larger quantity than in other grain, seems to form a combination with the starch and water, which renders wheaten bread more digestible than the other species of bread.*

The arrangement of many of the vegetable principles in the different parts of plants has been incidentally mentioned in this lecture; but a more particular statement is required to afford just views of the relation between their organization and chemical constitution, which is an object of great importance. The tubes and hexagonal cells in the vascular system of plants are composed of woody fibre; and when they are not filled with fluid matter they contain some of the solid materials which formed a constituent part of the fluids belonging to them.

In the roots, trunk, and branches, the bark, alburnum, and heart-wood, the leaves and flowers, the great basis of the solid parts is woody fibre. It forms by far the greatest part of the heart-wood and bark; there is less in the alburnum, and still less in the leaves and flowers. The alburnum of the birch contains so much sugar and mucilage, that it is sometimes used in the north of Europe as a substitute for bread. The leaves of the cabbage, broccoli, and seacale, contain much mucilage, and a little saccharine matter,

* In the process of the conversion of flour into bread, it has lately been ascertained that alcohol is formed as well as carbonic acid; thus approaching the panary fermentation (as the raising of bread has been sometimes called), to the vinous. But the proportion of alcohol produced appears to be small. What the changes effected are have not yet been thoroughly investigated, especially of the gluten.—J. D.

and a little albumen. From 1000 parts of the leaves of common cabbage, I obtained 41 parts of mucilage, 24 of sugar, and 8 of albuminous matter.

In bulbous roots, and sometimes in common roots, a large quantity of starch, albumen, and mucilage are often found deposited in the vessels; and they are most abundant after the sap has ceased to flow; and afford a nourishment for the early shoots made in spring. The potato is the bulb that contains the largest quantity of soluble matter in its cells and vessels; and it is of most importance in its application as food. Potatoes in general afford from one-fifth to one-seventh their weight of dry starch. From 100 parts of the common *Kidney potato*, Dr. Pearson obtained from 32 to 28 parts of meal, which contained from 23 to 20 of starch and mucilage; and 100 parts of the *Apple potato* in various experiments, afforded me from 18 to 20 parts of pure starch. From five pounds of the variety of the potato called *Captain hart*, Mr. Skrimshire, jun. obtained 12 ounces of starch, from the same quantity of the *Rough red* potato $10\frac{1}{2}$ ounces, from the *Moulton white* $11\frac{3}{4}$, from the *Yorkshire kidney*, $10\frac{3}{4}$ ounces, from *Hundred eyes* 9 ounces, from *Purple red* $8\frac{1}{2}$, from *Ox noble* $8\frac{1}{4}$. The other soluble substances in the potato are albumen and mucilage.

From the analysis of Einhoff it appears that 7680 parts of potato afford,

Of Starch - - -	1153
— Fibrous matter analogous to starch	540
— Albumen - - -	107
— Mucilage in the state of a saturated solution - - -	312
	2122

So that a fourth part of the weight of the potato at least may be considered as nutritive matter. Mr. Knight informs me, that he has found the best potatoes, such as the Irish apple, to possess much greater specific gravity than the inferior varieties; the specific gravity varying from 1075 to 1100, and it is probable that their nutritive properties are nearly proportionate to their specific gravities.

The turnip, carrot, and parsnip, afford principally saccharine, mucilaginous, and extractive matter. I obtained from 1000 parts of common turnips, 7 parts of mucilage, 34 of saccharine matter, and nearly 1 part of albumen. 1000 parts of carrots furnished 95 parts of sugar, 3 parts of mucilage, and $\frac{1}{2}$ part of extract; 1000 parts of parsnip afforded 90 parts of saccharine matter, and 9 parts of mucilage. The *Walcheren* or *white carrot*, gave, in 1000 parts, 98 parts of sugar, 2 parts of mucilage, and 1 of extract.

Fruits, in the organization of their soft parts, approach to the nature of bulbs. They contain a certain quantity of nourishment laid up in their cells for the use of the embryon plant; mucilage, sugar, starch, are found in many of them often combined with vegetable acids. Most of the fruit trees common in Britain have been naturalized on account of the saccharine matter they contain, which, united to the vegetable acids and mucilage, renders them at once agreeable to the taste, and nutritive.

The value of fruits for the manufacture of fermented liquors, may be judged of from the specific gravity of their expressed juices; but the quantity of juice and the consistence of the pulp differ widely in different species of fruits, and therefore the specific gravity of the fruit will not always indicate the value of its fermented produce. The best cider and perry are made from those apples and pears that afford the densest juices; and a comparison between different fruits may be made with tolerable accuracy by plunging them together into a saturated solution of salt, or a strong solution of sugar; those that sink deepest will afford the richest juice.*

Starch or coagulated mucilage forms the greatest part of the seeds and grains used for food; and they are generally combined with gluten, oil, or albuminous matter. In corn, with gluten; in peas and beans, with albuminous matter; and in rape seed, hemp seed, linseed, and the kernels of most nuts, with oils.

I found 100 parts of good full-grained wheat sown in autumn, to afford

Of Starch - -	77
— Gluten - -	19

100 parts of wheat sown in spring,

Of Starch - -	70
— Gluten - -	24

100 parts of Barbary wheat,

Of Starch - -	74
— Gluten - -	23

100 parts of Sicilian wheat,

Of Starch - -	75
— Gluten - -	21

I have examined different specimens of North American wheat; all of them have contained rather more gluten than the British. In general, the wheat of warm climates abounds more in gluten, and in insoluble parts; and it is of greater specific gravity, harder, and more difficult to grind.

The wheat of the south of Europe, in consequence of the larger quantity of gluten it contains, is peculiarly fitted for making macaroni, and other preparations of flour, in which a glutinous quality is considered as an excellence.

In some experiments made on barley, I obtained from 100 parts of full and fair Norfolk barley,

Of Starch - - - - -	79
— Gluten - - - -	6
— Husk - - - -	8

The remaining 7 parts saccharine matter. The sugar in barley is probably the chief cause why it is more proper for malting than any other species of grain.

Einhoff has published a minute analysis of barley meal. He found in 3840 parts,

Of volatile matter - -	360
— Albumen - - -	44
— Saccharine matter - -	200
— Mucilage - - -	176
— Phosphate of lime, with some albumen	9
— Gluten - - -	135
— Husk, with some gluten and starch	260
— Starch not quite free from gluten	2580
— Loss - - - - -	78

* The specific gravity of the expressed juice of the water melon, the most succulent of fruits, exceeds very little that of distilled water. One specimen of water melon, which I examined in Malta, yielded 97 parts of water, and 3 of solid matter, principally saccharine and mucilaginous.—J. D.

Rye afforded to Einhoff, in 3840 parts, 2520 meal, 930 husk, and 390 moisture; and the same quantity of meal analysed gave,

Of Starch - - -	2345
— Albumen - - -	116
— Mucilage - - -	426
— Saccharine matter - -	126
— Gluten not dried - -	364

Remainder husk and loss.

I obtained from 1000 parts of rye, grown in Suffolk, 61 parts of starch, and 5 parts of gluten.

100 parts of oats, from Sussex afforded me 59 parts of starch, 6 of gluten, and 2 of saccharine matter.

1000 parts of peas, grown in Norfolk, afforded me 501 parts of starch, 22 parts of saccharine matter, 35 parts of albuminous matter, and 16 parts of extract, which became insoluble during evaporation of the saccharine fluid.

From 3840 parts of marsh beans (*Vicia faba*), Einhoff obtained,

Of Starch - - -	1312
—Albumen - - - -	31
— Other matters which may be conceived nutritive; such as gummy, starchy, fibrous matter analogous to animal matter - - -	1204

The same quantity of kidney beans (*Phaseolus vulgaris*), afforded,

Of matter analogous to starch -	1805
— Albumen and matter approaching to animal matter in its nature	851
—Mucilage - - -	799

From 3840 parts of lentiles, he obtained 1260 parts of starch, and 1433 of a matter analogous to animal matter.

The matter analogous to animal matter is described by Einhoff, as a glutinous substance insoluble in water; soluble in alcohol; when dry, having the appearance of glue; probably a peculiar modification of gluten.

From 16 parts of hemp seed, Bucholz obtained 3 parts of oil, $3\frac{1}{2}$ parts of albumen, about $1\frac{3}{4}$ of saccharine and gummy matter. The insoluble husks and coats of the seed weighed $6\frac{1}{8}$ parts.

The different parts of flowers contain different substances: the pollen, or impregnating dust of the date, has been found by Fourcroy and Vauquelin to contain a matter analogous to gluten, and a soluble extract abounding in malic acid. Link found in the pollen of the hazel-tree, much tannin and gluten.

Saccharine matter is found in the nectarium of flowers, or the receptacles within the corolla, and by tempting the larger insects into the flowers, it renders the work of impregnation more secure; for the pollen is often by their means applied to the stigma; and this is particularly the case when the male and female organs are in different flowers or different plants.

It has been stated, that the fragrance of flowers depends upon the volatile oils they contain; and these oils, by their constant evaporation, surround the flower with a kind of odorous atmosphere; which at the same time that it entices larger insects, may probably preserve the parts of fructification from the ravages of smaller ones. Volatile oils, or odorous substances, seem particularly destructive to these minute insects and animalcules which feed on the substance of vegetables; thousands of aphides may be usually seen in the stalk and leaves of the rose; but none of them are ever observed on the flower. Camphor is used to preserve the collections of naturalists. The woods that contain aromatic oils are remarked for their indestructibility; and for their exemption from the attacks of insects: this is particularly the case with the cedar, rose-wood, and cypress. The gates of Constantinople, which were made of this last wood, stood entire from the time of Constantine, their founder, to that of Pope Eugene IV., a period of 1100 years.

The petals of many flowers afford saccharine and mucilaginous matter. The white lily yields mucilage abundantly; and the orange lily a mixture of mucilage and sugar; the petals of the convolvulus afford sugar, mucilage, and albuminous matter.

The chemical nature of the coloring matters of flowers has not as yet been subject to any very accurate observation. These coloring matters, in general, are very transient, particularly the blues and reds; alkalies change the colors of most flowers to green, and acids to red. An imitation of the coloring matter may be made by digesting solutions of gall-nuts with chalk: a green fluid is obtained, which becomes red by the action of an acid; and has its green color restored by means of alkalies.

The yellow coloring matters of flowers are the most permanent; the carthamus contains a red and a yellow coloring matter; the yellow coloring matter is easily dissolved by water, and from the red, rouge is prepared by a process which is kept secret.

The same substances as exist in the solid parts of plants are found in their fluids, with the exception of woody fibre. Fixed and volatile oils, containing resin or camphor, or analogous substances in solution, exist in the cylindrical tubes belonging to a number of plants. Different species of euphorbia emit a milky juice, which when exposed to air deposites a substance analogous to starch, and another similar to gluten.

Opium, gum elastic, gamboge, the poisons of the *Upas antiar* and *Tieute*, and other substances that exude from plants, may be considered as peculiar juices belonging to appropriate vessels.

The sap of plants, in general, is very compound in its nature; and contains more saccharine, mucilaginous, and albuminous matter in the alburnum; and most tannin and extract in the bark. The cambium, which is the mucilaginous fluid found in trees between the wood and the bark, and which is essential to the formation of new parts, seems to be derived from these two kinds of sap; and probably is a combination of the mucilaginous and albuminous matter of one, with the astringent matter of the other, in a state fitted to become organized by the separation of its watery parts.

The alburnous saps of some trees have been chemically examined by Vauquelin. He found in those of the elm, beech, yoke elm, hornbeam, and birch, extractive and mucilaginous matter, and acetic acid combined with potassa or lime. The solid matter afforded by their evaporation yielded an ammoniacal smell, probably owing to albumen: the sap of the birch afforded saccharine matter.

Deyeux in the sap of the vine and the yoke elm has detected a matter analogous to the curd of milk. I found a substance similar to albumen in the sap of the walnut tree.

I found the juice which exudes from the vessels of the marshmallow when cut, to be a solution of mucilage.

The fluids contained in the sap vessels of wheat and barley, afforded in some experiments which I made on them, mucilage, sugar, and a matter which coagulated by heat; which last was most abundant in wheat.

The following table contains a statement of the quantity of soluble or nutritive matters existing in varieties of the different substances that have been mentioned, and of some others which are used as articles of food, either for man or cattle. The analyses are my own; and were conducted with a view to a knowledge of the general nature and quantity of the products, and not of their intimate chemical composition. The soluble matters afforded by the grasses, except that from the fiorin in winter, were obtained by Mr. Sinclair, gardener to the Duke of Bedford, from given weights of the grasses cut when the seeds were ripe; they were sent to me by his Grace's desire for chemical examination, and form part of the results of an important and extensive series of experiments on grasses made by direction of the Duke, at Woburn Abbey, when pursuing those plans for the improvement of agriculture, the origin of which have thrown so much glory on the memory of his illustrious brother.

Table of the Quantities of soluble or nutritive Matters afforded by 1000 *Parts of different vegetable Substances.*

Vegetables or vegetable Substance.	Whole Quantity of soluble or nutritive matter.	Mucilage or Starch.	Saccharine matter or Sugar.	Gluten or Albumen.	Extract or matter rendered insoluble during evaporation.
Middlesex wheat, average crop	955	765	—	190	
Spring wheat	940	700	—	240	
Mildewed wheat of 1806	210	178	—	32	
Blighted wheat of 1804	650	520	—	130	
Thick-skinned Sicilian wheat of 1810	955	725	—	230	
Thin-skinned Sicilian wheat of 1810	961	722	—	239

Fiorin	54	46	5	1	2
Fiorin cut in winter	76	64	8	1	3

All these substances were submitted to experiment green, and in their natural states. It is probable that the excellence of the different articles, as food, will be found to be in a great measure proportional to the quantities of soluble or nutritive matters they afford; but still these quantities cannot be regarded as *absolutely* denoting their value. Albuminous or glutinous matters have the characters of animal substances; sugar is more nourishing, and extractive matter less nourishing, than any other principles composed of carbon, hydrogen, and oxygen. Certain combinations likewise of these substances may be more nutritive than others.

I have been informed by Sir Joseph Banks, that the Derbyshire miners, in winter, prefer oat-cakes to wheaten bread; finding that this kind of nourishment enables them to support their strength and perform their labour better. In summer, they say oat-cake heats them, and they then consume the finest wheaten bread they can procure. Even the skin of the kernel of oats probably has a nourishing power, and is rendered partly soluble in the stomach with the starch and gluten. In most countries of Europe, except Britain, and in Arabia, horses are fed with corn of different kinds, mixed with chopped straw; and the chopped straw seems to act the same part as the husk of the oat. In the mill 14 lbs. of good wheat yield on an average 13 lbs. of flour; the same quantity of barley 12 lbs., and of oats only 8 lbs.

In the south of Europe, hard or thin-skinned wheat is in higher estimation, than soft or thick-skinned wheat; the reason of which is obvious, from the larger quantity of gluten and nutritive matter it contains. I have made an analysis of only one specimen of thin-skinned wheat, so that other specimens may possibly contain more nutritive matter than that in the table; the Barbary and Sicilian wheats. before referred to, were thick-skinned wheats. In England, the difficulty of grinding thin-skinned wheat is an objection; but this difficulty is easily overcome by moistening the corn.*

LECTURE IV.

ON SOILS: THEIR CONSTITUENT PARTS. ON THE ANALYSIS OF SOILS. OF THE USES OF THE SOIL. OF THE ROCKS AND STRATA FOUND BENEATH SOILS. OF THE IMPROVEMENT OF SOIL.

No subjects are of more importance to the farmer than the nature and improvement of soils; and no parts of the doctrines of agriculture are more capable of being illustrated by chemical inquiries.

Soils are extremely diversified in appearance and quality; yet, as it was stated in the introductory lecture, they consist of different proportions of the same elements; which are in various states of chemical combination, or mechanical mixture.

The substances which constitute soils have been already mentioned. They are certain compounds of the earths, silica, lime, alumina, magnesia, and of the oxides of iron and manganesum; animal and vegetable matters in a decomposing state, and saline, acid, or alkaline combinations.

In all chemical experiments on the composition of soils connected with agriculture, the constituent parts obtained are compounds; and they act as compounds in nature; it is in this state, therefore, that I shall describe their characteristic properties.

1. *Silica*, or the earth of *flints*, in its pure and crystallized form, is the substance known by the name of rock crystal, or Cornish diamond. As it is procured by chemists, it appears in the form of a white impalpable powder. It is not soluble in the common acids, but dissolves by heat in fixed alkaline lixivia. It is an incombustible substance, for it is saturated with oxygen. I have proved it to be a compound of oxygen and the peculiar combustible body which I have named silicum; and from the experiments of Berzelius, it is probable that it contains nearly equal weights of these two elements.*

2. The sensible properties of *lime* are well known. It exists in soils usually united to carbonic acid, which is easily disengaged from it by the attraction of the common acids. It is sometimes found combined with the phosphoric and sulphuric acids. Its chemical properties and agencies in its pure state will be described in the lecture on manures, obtained from the mineral kingdom. It is soluble in nitric and muriatic acids, and forms a substance with sulphuric acid difficult of solution, called gypsum. It is not soluble in alkaline solutions. It consists of one proportion. 40 of the peculiar metallic substance, which I have named calcium; and one proportion 15 of oxygen.

---

* For the following note on this subject I am indebted to the kindness of the Right Hon. Sir Joseph Banks, Bart. K. B.:—

Information received from John Jeffrey, Esq., his Majesty's Consul-General at Lisbon, in answer to Queries transmitted to him, from the Comm. of P. C. for Trade, dated Jan. 12, 1812.

To grind hard corn with the mill-stones used in England, the wheat must be well screened, then sprinkled with water at the miller's discretion, and laid in heaps and frequently turned and thoroughly mixed, which will soften the husk, so as to make it separate from the flour in grinding, and of course give the flour a brighter colour; otherwise the flinty quality of the wheat, and the thinness of the skin, will prevent its separation, and will render the flour unfit for making into bread.

I am informed by a miller of considerable experience, and who works his mills entirely with the stones from England or Ireland, that he frequently prepares the hard Barbary corn by immersing it in water in close wicker baskets, and spreading it thinly on a floor to dry; much depends on the judgment and skill of the miller in preparing the corn for the mill according to its relative quality. I beg to observe, that it is not from this previous process of wetting the corn that the weight in the flour of hard corn is increased; but from its natural quality it imbibes considerably more water in making it into bread. The mill-stones must not be cut too deep, but the furrows very fine, and picked in the usual way. The mills should work with less velocity in grinding hard corn than with soft, and set to work at first with soft corn, till the mill ceases to work well; then put on the hard corn. Hard wheat always sells at a higher price in the market than soft wheat, on an average of ten to fifteen per cent.; as it produces more flour in proportion, and less bran than the soft corn.

Flour made from hard wheat is more esteemed than what is made from soft corn; and both sorts are applied to every purpose.

The flour of hard wheat is in general superior to that made from soft; and there is no difference in the process of making them into bread; but the flour from hard wheat will imbibe and retain more water in making into bread, and will consequently produce more weight of bread: it is the practice here, and which I am persuaded it would be advisable to adopt in England, to make bread with flour of hard and soft wheat, which by being mixed, will make the bread much better.

(Signed) JOHN JEFFREY.

* According to the later experiments of Berzelius, silica consists of 48·4 inflammable basis, and of 51·6 oxygen.—J. D.

3. *Alumina* exists in a pure and crystallized state in the white sapphire, and united to a little oxide of iron and silica in the other oriental gems.

In the state in which it is procured by chemists, it appears as a white powder, soluble in acids and fixed alkaline liquors. From my experiments, it appears that alumina consists of one proportion 33 of aluminum, and one 15 of oxygen.

4. *Magnesia* exists in a pure crystallized state, constituting a mineral like talc found in North America. In its common form it is the *magnesia usta*, or calcined magnesia of druggists. It generally exists in soils combined with carbonic acid. It is soluble in all the mineral acids; but not in alkaline lixivia. It is distinguished from the other earths found in soils by its ready solubility in solutions of alkaline carbonates, saturated with carbonic acid. It appears to consist of 38 magnesium and 15 oxygen.

5. There are two well-known *oxides of iron*, the black and the brown. The black is the substance that flies off when red-hot iron is hammered. The brown oxide may be formed by keeping the black oxide red-hot for a long time in contact with air. The first seems to consist of one proportion of iron 103, and two of oxygen 30: and the second of one proportion of iron 103, and three proportions of oxygen 45. The oxides of iron sometimes exist in soils combined with carbonic acid. They are easily distinguished from other substances by their giving, when dissolved in acids, a black color to solution of galls, and a bright blue precipitate to solution of prussiate of potassa and iron.

6. *The oxide of manganesum* is the substance commonly called manganese, and used in bleaching. It appears to be composed of one proportion of manganesum 113, and three of oxygen 45. It is distinguished from the other substances found in soils, by its property of decomposing muriatic acid, and converting it into chlorine.

7. *Vegetable and animal matters* are known by their sensible qualities, and by their property of being decomposed by heat. Their characters may be learned from the details in the last lecture.

8. The *saline compounds* found in soils, are common salt, sulphate of magnesia, sometimes sulphate of iron, nitrates of lime and of magnesia, sulphate of potassa, and carbonates of potassa and soda.* To describe their characters minutely will be unnecessary: the tests for most of them have been already noticed.

The silica in soils is usually combined with alumina and oxide of iron, or with alumina, lime, magnesia, and oxide of iron, forming gravel and sand of different degrees of fineness. The carbonate of lime is usually in an impalpable form; but sometimes in the state of calcareous sand. The magnesia, if not combined in the gravel and sand of soil, is in a fine powder united to carbonic acid. The impalpable part of the soil, which is usually called clay or loam, consists of silica, alumina, lime, and magnesia; and is, in fact, usually of the same composition as the hard sand, but more finely divided. The vegetable or animal matters (and the first is by far the most common in soils), exist in different states of decomposition. They are sometimes fibrous, sometimes entirely broken down and mixed with the soil.

To form a just idea of soils, it is necessary to conceive different rocks decomposed, or ground into parts and powder of different degrees of fineness, some of their soluble parts dissolved by water, and that water adhering to the mass, and the whole mixed with larger or smaller quantities of the remains of vegetables and animals in different stages of decay.

It will be necessary to describe the processes by which all the varieties of soils may be analyzed. I shall be minute in these particulars, and, I fear, tedious; but the philosophical farmer will, I trust, feel the propriety of full details on this subject.

The instruments required for the analysis of soils are few, and but little expensive. They are, a balance capable of containing a quarter of a pound of common soil, and capable of turning when loaded with a grain; a set of weights from a quarter of a pound troy to a grain; a wire sieve, sufficiently coarse to admit a mustard seed through its apertures; an Argand lamp and stand; some glass bottles; Hessian crucibles; procelain, or queen's ware evaporating basins; a Wedgewood pestle and mortar; some filters made of half a sheet of blotting paper, folded so as to contain a pint of liquid, and greased at the edges; a bone knife, and an apparatus for collecting and measuring aëriform fluids.

The chemical substances or re-agents required for separating the constituent parts of the soil, have, for the most part, been mentioned before; they are muriatic acid *(spirit of salt,)* sulphuric acid, pure volatile alkali dissolved in water, solution of prussiate of potash and iron, succinate of ammonia, soap lie, or solution of potassa, solutions of carbonate of ammonia, or muriate of ammonia, of neutral carbonate of potash, and nitrate of ammoniac.

In cases when the general nature of the soil of a field is to be ascertained, specimens of it shonld be taken from different places, two or three inches below the surface, and examined as to the similarity of their properties. It sometimes happens, that upon plains the whole of the upper stratum of the land is of the same kind, and in this case one analysis will be sufficient; but in valleys, and near the beds of rivers, there are very great differences, and it now and then occurs that one part of a field is calcareous, and another part siliceous; and in this case, and in analogous cases, the portions different from each other should be separately submitted to experiment.

Soils, when collected, if they cannot be immediately examined, should be preserved in phials quite filled with them, and closed with ground-glass stoppers.

The quantity of soil most convenient for a perfect analysis, is from two to four hundred grains. It should be collected in dry weather, and exposed to the atmosphere till it becomes dry to the touch.

The specific gravity of a soil, or the relation of its weight to that of water, may be ascertained by introducing into a phial, which will contain a known quantity of water, equal volumes of water and of soil; and this may be easily done by pouring in water till it is half full, and then adding the soil till the fluid rises to the mouth; the difference

* In some soils, especially in Spain and in Bengal, nitre is an ingredient formed by the intervention of carbonate of lime, by the union of alkali in the soil, and of nitric acid, the elements of which are derived from the atmosphere.—J. D.

between the weight of the soil and that of the water will give the result.* Thus, if the bottle contains four hundred grains of water, and gains two hundred grains when half filled with water and half with soil, the specific gravity of the soil will be 2; that is, it will be twice as heavy as water; and if it gained 165 grains, its specific gravity would be 1825, water being 1000.

It is of importance that the specific gravity of a soil should be known, as it affords an indication of the quantity of animal and vegetable matter it contains; these substances being always most abundant in the lighter soils.

The other physical properties of soils should likewise be examined before the analysis is made, as they denote, to a certain extent, their composition, and serve as guides in directing the experiments. Thus, siliceous soils are generally rough to the touch, and scratch glass when rubbed upon it; ferruginous soils are of a red or yellow colour; and calcareous soils are soft.†

1. Soils, though as dry as they can be made by continued exposure to air, in all cases still contain a considerable quantity of water, which adheres with great obstinacy to the earths and animal and vegetable matter, and can only be driven off from them by a considerable degree of heat. The first process of analysis is, to free the given weight of soil from as much of this water as possible, without in other respects affecting its composition; and this may be done by heating it for ten or twelve minutes over an Argand's lamp, in a basin of porcelain, to a temperature equal to 300 Fahrenheit; and if a thermometer is not used, the proper degree may be easily ascertained, by keeping a piece of wood in contact with the bottom of the dish; as long as the color of the wood remains unaltered, the heat is not too high; but when the wood begins to be charred, the process must be stopped. A small quantity of water will, perhaps, remain in the soil even after this operation, but it always affords useful comparative results; and if a higher temperature were employed, the vegetable or animal matter would undergo decomposition, and in consequence the experiment be wholly unsatisfactory.

The loss of weight in the process should be carefully noted, and when in 400 grains of soil it reaches as high as 50, the soil may be considered as in the greatest degree absorbent, and retentive of water, and will generally be found to contain much vegetable or animal matter, or a large proportion of aluminous earth. When the loss is only from 20 to 10, the land may be considered as only slightly absorbent and retentive, and siliceous earth probably forms the greatest part of it.

2. None of the loose stones, gravel, or large vegetable fibres, should be divided from the pure soil till after the water is drawn off; for these bodies are themselves often highly absorbent and retentive, and, in consequence, influence the fertility of the land. The next process, however, after that of heating, should be their separation, which may be easily accomplished by the sieve, after the soil has been gently bruised in a mortar. The weights of the vegetable fibres or wood, and of gravel and stones, should be separately noted down, and the nature of the last ascertained; if calcareous, they will effervesce with acids; if siliceous, they will be sufficiently hard to scratch glass; and if of the common aluminous class of stones, they will be soft, easily cut with a knife, and incapable of effervescing with acids.

3. The greater number of soils, besides gravel and stones, contain larger or smaller proportions of sand of different degrees of fineness; and it is a necessary operation, the next in the process of analysis, to detach them from the parts in a state of more minute division, such as clay, loam, marl, vegetable and animal matter, and the matter soluble in water. This may be effected in a way sufficiently accurate, by boiling the soil in three or four times its weight of water; and when the texture of the soil is broken down, and the water cool, by agitating the parts together, and then suffering them to rest. In this case, the coarse sand will generally separate in a minute, and the finer in two or three minutes, whilst the highly-divided earthy, animal, or vegetable matter, will remain in a state of mechanical suspension for a much longer time; so that by pouring the water from the bottom of the vessel, after one, two, or three minutes, the sand will be principally separated from the other substances, which, with the water containing them, must be poured into a filter, and after the water has passed through, collected, dried, and weighed. The sand must likewise be weighed, and the respective quantities noted down. The water of lixiviation must be preserved, as it will be found to contain the saline and soluble animal or vegetable matters, if any exist in the soil.

4. By the process of washing and filtration, the soil is separated into two portions, the most important of which is generally the finely-divided matter. A minute analysis of the sand is seldom or never necessary, and its nature may be detected in the same manner as that of the stones or gravel. It is always either siliceous sand, or calcareous sand, or a mixture of both. If it consist wholly of carbonate of lime, it will be rapidly soluble in muriatic acid with effervescence; but if it consist partly of this substance, and party of siliceous matter, the respective quantities may be ascertained by weighing the residuum after the action of the acid, which must be applied till the mixture has acquired a sour taste, and has ceased to effervesce. This residuum is the siliceous part; it must be washed, dried, and heated strongly in a crucible; the difference between the weight of it and the weight of the whole indicates the proportion of calcareous sand.

5. The finely-divided matter of the soil is usually very compound in its nature; it sometimes contains all the four primitive earths of soils, as well as animal and vegetable matter; and to ascertain the proportions of these with tolerable accuracy is the most difficult part of the subject.

The first process to be performed in this part of the analysis is the exposure of the fine matter of the soil to the action of muriatic acid. This substance should be poured upon the earthy matter in an evaporating basin, in a quantity equal to twice the weight of the earthy matter; but diluted with double its volume of water. The mixture should

* It may be more accurately and easily accomplished by weighing it in air and in water in a light phial carefully counterpoised.—J. D.

† Clay soils, breathed on, emit a peculiar odor, called the earthy.—J. D.

be often stirred, and suffered to remain for an hour, or an hour and a half, before it is examined.

If any carbonate of lime or of magnesia exist in the soil, they will have been dissolved in this time by the acid, which sometimes takes up likewise a little oxide of iron; but very seldom any alumina.

The fluid should be passed through a filter; the solid matter collected, washed with rain water, dried at a moderate heat, and weighed. Its loss will denote the quantity of solid matter taken up. The washings must be added to the solution, which, if not sour to the taste, must be made so by the addition of fresh acid, when a little solution of prussiate of potassa and iron must be mixed with the whole. If a blue precipitate occurs, it denotes the presence of oxide of iron, and the solution of the prussiate must be dropped in till no farther effect is produced. To ascertain its quantity, it must be collected in the same manner as other solid precipitates, and heated red; the result is oxide of iron, which may be mixed with a little oxide of manganesum.

Into the fluid freed from oxide of iron, a solution of neutralized carbonate of potash must be poured, till all effervescence ceases in it, and till its taste and smell indicate a considerable excess of alkaline salt.

The precipitate that falls down is carbonate of lime; it must be collected on the filter, and dried at a heat below that of redness.

The remaining fluid must be boiled for a quarter of an hour, when the magnesia, if any exist, will be precipitated from it, combined with carbonic acid, and its quantity is to be ascertained in the same manner as that of the carbonate of lime.

If any minute proportion of alumina should, from peculiar circumstances, be dissolved by the acid, it will be found in the precipitate with the carbonate of lime, and it may be separated from it by boiling it for a few minutes with soap lie, sufficient to cover the solid matter: this substance dissolves alumina, without acting upon carbonate of lime.

Should the finely-divided soil be sufficiently calcareous to effervesce very strongly with acids, a very simple method may be adopted for ascertaining the quantity of carbonate of lime, and one sufficiently accurate in all common cases.

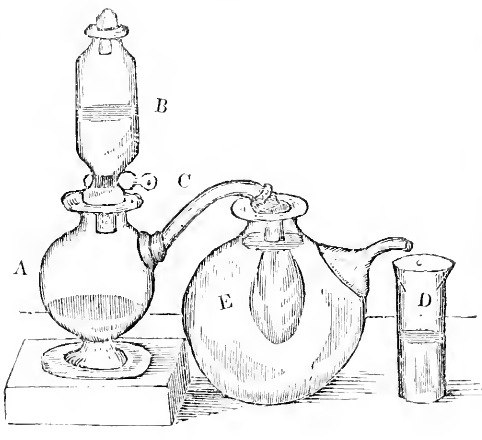
Carbonate of lime, in all its states, contains a determinate proportion of carbonic acid, *i. e.* nearly 43 per cent., so that when the quantity of this elastic fluid given out by any soil during the solution of its calcareous matter in an acid is known, either in weight or measure, the quantity of carbonate of lime may be easily discovered.

When the process by diminution of weight is employed, two parts of the acid and one part of the matter of the soil must be weighed in two separate bottles, and very slowly mixed together till the effervescence ceases: the difference between their weight before and after the experiment denotes the quantity of carbonic acid lost; for every four grains and a quarter of which, ten grains of carbonate of lime must be estimated.

The best method of collecting the carbonic acid, so as to discover its volume, is by a peculiar pneumatic apparatus,* in which its bulk may be measured by the quantity of water it displaces.

6. After the calcareous parts of the soil have been acted upon by muriatic acid, the next process is to ascertain the quantity of finely-divided insoluble animal and vegetable matter that it contains.

Fig. 15.



This may be done with sufficient precision, by strongly igniting it in a crucible over a common fire till no blackness remains in the mass. It should be often stirred with a metallic rod, so as to expose new surfaces continually to the air; the loss of weight that it undergoes denotes the quantity of the substance that it contains destructible by fire and air.*

It is not possible, without very refined and difficult experiments, to ascertain whether this substance is wholly animal or vegetable matter, or a mixture of both. When the smell emitted during the incineration is similar to that of burnt feathers, it is a certain indication of some substance either animal or analogous to animal matter; and a copious blue flame at the time of ignition almost

* Fig. 15. A, B, C, D, represent the different parts of this apparatus. A represents the bottle for receiving the soil. B the bottle containing the acid, furnished with a stop-cock. C the tube connected with a flaccid bladder. D the graduated measure. E the bottle for containing the bladder. When this instrument is used, a given quantity of soil is introduced into A. B is filled with muriatic acid diluted with an equal quantity of water; and the stop-cock being closed, is connected with the upper orifice of A, which is ground to receive it. The tube D is introduced into the lower orifice of A, and the bladder connected with it placed in its flaccid state into E, which is filled with water. The graduated measure is placed under the tube of E. When the stop-cock of B is turned, the acid flows into A, and acts upon the soil; the elastic fluid generated passes through C into the bladder, and displaces a quantity of water in E equal to it in bulk, and this water flows through the tube into the graduated measure; and gives by its volume the indication of the proportion of carbonic acid disengaged from the soil; for every ounce measure of which two grains of carbonate of lime may be estimated.

* When the soil is aluminous, part of the loss in the above process will be owing to water driven off. Pure hydrate of alumina contains about 58 per cent. water; the whole of which can only be expelled by a white heat. On this account the ascertaining with any accuracy the proportion of animal and vegetable matter in a soil is difficult, and requires much chemical skill.—J. D.

always denotes a considerable proportion of vegetable matter. In cases when it is necessary that the experiments should be very quickly performed, the destruction of the decomposable substances may be assisted by the agency of nitrate of ammoniac, which at the time of ignition may be thrown gradually upon the heated mass, in the quantity of twenty grains for every hundred of residual soil. It accelerates the dissipation of the animal and vegetable matter, which it causes to be converted into elastic fluids; and it is itself at the same time decomposed and lost.

7. The substances remaining after the destruction of the vegetable and animal matter are generally minute particles of earthy matter, containing usually alumina and silica, with combined oxide of iron, or of manganesum.

To separate these from each other, the solid matter should be boiled for two or three hours with sulphuric acid, diluted with four times its weight of water: the quantity of the acid should be regulated by the quantity of solid residuum to be acted on, allowing for every 100 grains 2 drachms or 120 grains of acid.

The substance remaining after the action of the acid may be considered as siliceous; and it must be separated, and its weight ascertained, after washing and drying in the usual manner.

The alumina and the oxide of iron and manganesum, if any exist, are all dissolved by the sulphuric acid: they may be separated by succinate of ammonia, added to excess, which throws down the oxide of iron; and by soap lie, which will dissolve the alumina, but not the oxide of manganesum; the weights of the oxides ascertained after they have been heated to redness will denote their quantities.

Should any magnesia and lime have escaped solution in the muriatic acid, they will be found in the sulphuric acid; this, however, is rarely the case; but the process for detecting them and acertaining their quantities, is the same in both instances.

The method of analysis by sulphuric acid is sufficiently precise for all usual experiments; but if very great accuracy be an object, dry carbonate of potassa must be employed as the agent, and the residuum of the incineration (6) must be heated red for half an hour, with four times its weight of this substance, in a crucible of silver, or of well-baked porcelain. The mass obtained must be dissolved in muriatic acid, and the solution evaporated till it is nearly solid; distilled water must then be added, by which the oxide of iron and all the earths, except silica, will be dissolved in combination as muriates. The silica, after the usual process of lixiviation, must be heated red: the other substances may be separated in the same manner as from the muriatic and sulphuric solutions.

This process is the one usually employed by chemical philosophers for the analysis of stones.

8. If any saline matter, or soluble vegetable or animal matter is suspected in the soil, it will be found in the water of lixiviation used for separating the sand.

This water must be evaporated to dryness in a proper dish, at a heat below its boiling point.

If the solid matter obtained is of a brown color and inflammable, it may be considered as partly vegetable extract. If its smell, when exposed to heat, be like that of burnt feathers, it contains animal or albuminous matter; if it be white, crystalline, and not destructible by heat, it may be considered as principally saline matter; the nature of which may be known by the tests already described.

9. Should sulphate or phosphate of lime be suspected in the entire soil, the detection of them requires a particular process upon it. A given weight of it, for instance, 400 grains, must be heated red for half an hour in a crucible, mixed with one-third of powdered charcoal. The mixture must be boiled for a quarter of an hour, in a-half pint of water, and the fluid collected through the filter, and exposed for some days to the atmosphere in an open vessel. If any notable quantity of sulphate of lime *(gypsum)* existed in the soil, a white precipitate will gradually form in the fluid, and the weight of it will indicate the proportion.

Phosphate of lime, if any exist, may be separated from the soil after the process for gypsum. Muriatic acid must be digested upon the soil, in quantity more than sufficient to saturate the soluble earths; the solution must be evaporated, and water poured upon the solid matter. This fluid will dissolve the compounds of earths with the muriatic acid, and leave the phosphate of lime untouched. It would not fall within the limits assigned to this lecture to detail any processes for the detection of substances which may be accidentally mixed with the matters of soils. Other earths and metallic oxides are now and then found in them, but in quantities too minute to bear any relation to fertility or barrenness, and the search for them would make the analysis much more complicated, without rendering it more useful.

10. When the examination of a soil is completed, the products should be numerically arranged, and their quantities added together; and if they nearly equal the original quantity of soil, the analysis may be considered as accurate. It must, however, be noticed, that when phosphate or sulphate of lime is discovered by the independent process just described (9), a correction must be made for the general process, by subtracting a sum equal to their weight from the quantity of carbonate of lime obtained by precipitation from the muriatic acid.

In arranging the products, the form should be in the order of the experiments by which they were procured.

Thus, I obtained from 400 grains of a good siliceous sandy soil from a hop-garden near Tunbridge, Kent,

The loss in this analysis is not more than usually occurs, and it depends upon the impossibility of collecting the whole quantities of the different precipitates, and upon the presence of more moisture than is accounted for in the water of absorption, and which is lost in the different processes.

When the experimenter is become acquainted with the use of the different instruments, the properties of the re-agents, and the relations between the external and chemical qualities of soils, he will seldom find it necessary to perform, in any one case, all the processes that have been described. When his soil, for instance, contains no notable proportion of calcareous matter, the action of the muriatic acid (7) may be omitted. In examining peat soils, he will principally have to attend to the operation by fire and air (8): in the analysis of chalks and loams, he will often be able to omit the experiment by sulphuric acid (9); and when a soil is extremely dense and heavy, and after being heated to redness, strongly attracted by the magnet, he must particularly attend to the quantity of iron it contains; and, in this case, the muriatic acid will be the principal agent.

In the first trials that are made by persons unacquainted with chemistry, they must not expect much precision of result. Many difficulties will be met with; but in overcoming them, the most useful kind of practical knowledge will be obtained; and nothing is so instructive in experimental science as the detection of mistakes. The correct analyst ought to be well grounded in general chemical information; but, perhaps, there is no better mode of gaining it, than that of attempting original investigations. In pursuing his experiments, he will be continually obliged to learn the properties of the substances he is employing or acting upon; and his theoretical ideas will be more valuable in being connected with practical operations, and acquired for the purpose of discovery.

Plants, being possessed of no locomotive powers, can grow only in places where they are supplied with food; and the soil is necessary to their existence, both as affording them nourishment and enabling them to fix themselves in such a manner as to obey those mechanical laws by which their radicles are kept below the surface, and their leaves exposed to the free atmosphere. As the systems of roots, branches, and leaves are very different in different vegetables, so they flourish most in different soils; the plants that have bulbous roots, require a looser and a lighter soil than such as have fibrous roots; and the plants possessing only short fibrous radicles demand a firmer soil than such as have tap roots, or extensive lateral roots.

A good turnip soil from Holkham, Norfolk, afforded me 8 parts out of 9 siliceous sand; and the finely divided matter consisted

Of carbonate of lime	63
— silica	15
— alumina	11
— oxide of iron	3
Of vegetable and saline matter	5
— moisture	3

I found the soil taken from a field at Sheffield Place, in Sussex, remarkable for producing flourishing oaks, to consist of six parts of sand, and one part of clay and finely divided matter. And 100 parts of the entire soil submitted to analysis produced,

Silica	54
Alumina	28
Carbonate of lime	3
Oxide of iron	5
Decomposing vegetable matter	4
Moisture and loss	6

An excellent wheat soil from the neighborhood of West Drayton, Middlesex, gave 3 parts in 5 of siliceous sand; and the finely divided matter consisted of

Carbonate of lime	28
Silica	32
Alumina	29
Animal or vegetable matter and moisture	11

Of these soils the last was by far the most, and the first the least, coherent in texture. In all cases the constituent parts of the soil which give tenacity and coherence are the finely divided matters; and they possess the power of giving those qualities the highest degree when they contain much alumina. A small quantity of finely divided matter is sufficient to fit a soil for the production of turnips and barley; and I have seen a tolerable crop of turnips on a soil containing 11 parts out of 12 sand. A much greater proportion of sand, however, always produces absolute sterility. The soil of Bagshot heath, which is entirely devoid of vegetable covering, contains less than one-twentieth of finely divided matter. 400 parts of it, which had been heated red, afforded me 380 parts of coarse siliceous sand, 9 parts of fine siliceous sand, and 11 parts of impalpable matter, which was a mixture of ferruginous clay with carbonate of lime.* Vegetable or animal matters, when finely divided, not only give coherence, but likewise softness and penetrability; but neither they nor any other part of the soil must be in too great proportion; and a soil is unproductive if it consist entirely of impalpable matter.

Pure alumina or silica, pure carbonate of lime,

* When the climate is favorable and there is sufficient moisture, shrubs occasionally grow and flourish in soils nearly purely siliceous. As a striking example, I may mention the soil of the cinnamon garden in the neighborhood of Colombo, in the island of Ceylon. In many spots where this valuable plant flourishes most, the surface of the ground is white as snow, being pure quartz-sand; below the surface a few inches, where the roots penetrate, the sand is of a gray color. A specimen of this, dried thoroughly, was found to consist of

98·5	Siliceous sand
1·0	Vegetable matter
0·5	Water.

In my work, entitled "An Account of the Interior of Ceylon," other instances are given of soils, composed chiefly of siliceous earths, admitting of cultivation in that climate. Reflecting on this, I am disposed to think that in estimating the power of a soil, in relation to fertility, great attention should be paid to situation, in connexion with water. Probably a nearly pure siliceous soil may be fertile which admits of being well watered, care being taken to give it manure. *Vide* p. 622.—J. D.

or carbonate of magnesia, are incapable of supporting healthy vegetation.

No soil is fertile that contains as much as 19 parts out of 20 of any of the constituents that have been mentioned.

It will be asked, are the pure earths in the soil merely active as mechanical or indirect chemical agents, or do they actually afford food to the plant? This is an important question; and not difficult of solution.

The earths consist, as I have before stated, of metals, united to oxygen; and these metals have not been decomposed; there is consequently no reason to suppose that the earths are convertible into the elements of organized compounds, into carbon, hydrogen, and azote.

Plants have been made to grow in given quantities of earth. They consume very small portions only, and what is lost may be accounted for by the quantities found in their ashes; that is to say, it has not been converted into any new products.

The carbonic acid united to lime or magnesia, if any stronger acid happens to be formed in the soil during the fermentation of vegetable matter, which will disengage it from the earths, may be decomposed: but the earths themselves cannot be supposed convertible into other substances by any process taking place in the soil.

In all cases, the ashes of plants contain some of the earths of the soil in which they grow; but these earths, as may be seen from the table of the ashes afforded by different plants given in the last Lecture, never equal more than $\frac{1}{50}$ of the weight of the plant consumed.

If they be considered as necessary to the vegetable, it is as giving hardness and firmness to its organization. Thus, it has been mentioned that wheat, oats, and many of the hollow grasses, have an epidermis principally of siliceous earth; the use of which seems to be to strengthen them, and defend them from the attacks of insects and parasitical plants.

Many soils are popularly distinguished as *cold;* and the distinction, though at first view it may appear to be founded on prejudice, is really just.

Some soils are much more heated by the rays of the sun, all other circumstances being equal, than others; and soils brought to the same degree of heat cool in different times, *i. e.* some cool much faster than others.

This property has been very little attended to in a philosophical point of view; yet it is of the highest importance in agriculture. In general, soils that consist principally of a stiff white clay are difficultly heated; and being usually very moist, they retain their heat only for a short time. *Chalks* are similar in one respect, that they are difficultly heated; but being drier they retain their heat longer, less being consumed in causing the evaporation of their moisture.

A black soil, containing much soft vegetable matter, is most heated by the sun and air; and the colored soils, and the soils containing much carbonaceous matter, or ferruginous matter, exposed under equal circumstances to the sun, acquire a much higher temperature than pale-colored soils.

When soils are perfectly dry, those that most readily become heated by the solar rays likewise cool most rapidly, their power of losing heat by radiation being greatest; but I have ascertained, by experiment, that the darkest colored dry soil, (that which contains abundance of animal or vegetable matter, substances which most facilitate the diminution of temperature,) when heated to the same degree, provided it be within the common limits of the effect of solar heat, will cool more slowly than a wet pale soil, entirely composed of earthy matter.

I found that a rich black mould, which contained nearly $\frac{1}{4}$ of the vegetable matter, had its temperature increased in an hour from 65° to 88° by exposure to sunshine; whilst a chalk soil was heated only to 69° under the same circumstances. But the mould removed into the shade, where the temperature was 62°, lost, in half an hour, 15°; whereas the chalk, under the same circumstances, had lost only 4°.

A brown fertile soil and a cold barren clay were each artificially heated to 88°, having been previously dried: they were then exposed in a temperature of 57°; in half an hour the dark soil was found to have lost 9° of heat; the clay had lost only 6°. An equal portion of the clay containing moisture, after being heated to 88°, was exposed in a temperature of 55°; in less than a quarter of an hour, it was found to have gained the temperature of the room. The soils in all these experiments were placed in small tin plate trays two inches square, and half an inch in depth, and the temperature ascertained by a delicate thermometer.

Nothing can be more evident than that the genial heat of the soil, particularly in spring, must be of the highest importance to the rising plant. And when the leaves are fully developed, the ground is shaded, and any injurious influence, which in the summer might be expected from too great a heat, entirely prevented; so that the temperature of the surface, when bare and exposed to the rays of the sun, affords at least one indication of the degrees of its fertility; and the thermometer may be sometimes a useful instrument to the purchaser or improver of lands.

There is a very simple test of the cooling or radiating powers of soils, the formation of dew upon them, or their relative increase of weight by exposure to the air after being dried, in the day or the night, in sunshine or in shade. The soil that radiates most heat acquires the greatest increase of weight; and of course the radiating powers of the soil are not only connected with its temperature, but likewise with its relations to moisture.

The moisture in the soil influences its temperature; and the manner in which it is distributed through, or combined with, the earthy materials, is of great importance in relation to the nutriment of the plant. If water is too strongly attracted by the earths, it will not be absorbed by the roots of the plants; if it is in too great quantity, or too loosely united to them, it tends to injure or destroy the fibrous parts of the roots.

There are two states in which water seems to exist in the earths, and in animal and vegetable substances: in the first state it is united by chemical, in the other by cohesive, attraction.

If pure solution of ammonia or potassa be poured into a solution of alum, alumina falls down combined with water; and the powder dried by exposure to air will afford more than half its weight of water by distillation; in this instance the water is united by chemical attraction. The moisture which wood, or muscular fibre, or gum, that have been heated to 212°, afford by distillation at a red heat, is likewise water, the elements of which were united in the substance by chemical combination.

When pipe-clay dried at the temperature of the atmosphere is brought in contact with water, the fluid is rapidly absorbed: this is owing to cohesive attraction. Soils in general, vegetable and animal substances, that have been dried at a heat below that of boiling water, increase in weight by exposure to air, owing to their absorbing water existing in the state of vapor in the air, in consequence of cohesive attraction.

The water *chemically combined* amongst the elements of soils, unless in the case of the decomposition of animal or vegetable substances, cannot be absorbed by the roots of plants; but that *adhering* to the parts of the soil is in constant use in vegetation. Indeed, there are few mixtures of the earths found in soils that contain any chemically combined water; water is expelled from the earths by most substances that combine with them. Thus, if a combination of lime and water be exposed to carbonic acid; the carbonic acid takes the place of water; and compounds of alumina and silica, or other compounds of the earths, do not chemically unite with water; and soils, as it has been stated, are formed either by earthy carbonates, or compounds of the pure earths and metallic oxides.

When saline substances exist in soils, they may be united to water both chemically and mechanically; but they are always in too small a quantity to influence materially the relations of the soil to water.

The power of the soil to absorb water by cohesive attraction depends in great measure upon the state of division of its parts; the more divided they are, the greater is their absorbent power. The different constituent parts of soils likewise appear to act, even by cohesive attraction, with different degrees of energy. Thus vegetable substances seem to be more absorbent than animal substances; animal substances more so than compounds of alumina and silica; and compounds of alumina and silica more absorbent than carbonates of lime and magnesia: these differences may, however, possibly depend upon the differences in their state of division, and upon the surface exposed.

The power of soils to absorb water from air is much connected with fertility. When this power is great, the plant is supplied with moisture in dry seasons; and the effect of evaporation in the day is counteracted by the absorption of aqueous vapor from the atmosphere, by the interior parts of the soil during the day, and by both the exterior and interior during the night.

The stiff clays approaching to pipe clays in their nature, which take up the greatest quantity of water when it is poured upon them in a fluid form, are not the soils which absorb most moisture from the atmosphere in dry weather. They cake, and present only a small surface to the air; and the vegetation on them is generally burnt up almost as readily as on sands.

The soils that are most efficient in supplying the plant with water by atmospheric absorption are those in which there is a due mixture of sand, finely divided clay, and carbonate of lime, with some animal or vegetable matter; and which are so loose and light as to be freely permeable to the atmosphere. With respect to this quality, carbonate of lime and animal and vegetable matter are of great use in soils, they give absorbent power to the soil without giving it likewise tenacity: sand, which also destroys tenacity, on the contrary, gives little absorbent power.

I have compared the absorbent powers of many soils with respect to atmospheric moisture, and I have always found it greatest in the most fertile soils; so that it affords one method of judging of the productiveness of land.

1000 parts of a celebrated soil from Ormistown, in East Lothian, which contained more than half its weight of finely divided matter, of which 11 parts were carbonate of lime and 9 parts vegetable matter, when dried at 212°, gained in an hour by exposure to air saturated with moisture, at temperature 62°, 18 grains.

1000 parts of a very fertile soil from the banks of the river Parret, in Somersetshire, under the same circumstances, gained 16 grains.

1000 parts of a soil from Mersea, in Essex, worth 45 shillings an acre, gained 13 grains.

1000 grains of a fine sand from Essex, worth 28 shillings an acre, gained 11 grains.

1000 of a coarse sand, worth 15 shillings an acre, gained only 8 grains.

1000 of the soil of Bagshot heath gained only 3 grains.

Water, and the decomposing animal and vegetable matter existing in the soil, constitute the true nourishment of plants: and as the earthy parts of the soil are useful in retaining water, so as to supply it in the proper proportions to the roots of the vegetables, so they are likewise efficacious in producing the proper distribution of the animal or vegetable matter: when equally mixed with it, they prevent it from decomposing too rapidly; and by their means the soluble parts are supplied in proper proportions.

Besides this agency, which may be considered as mechanical, there is another agency between soils and organizable matters, which may be regarded as chemical in its nature. The earths, and even the earthy carbonates, have a certain degree of chemical attraction for many of the principles of vegetable and animal substances. This is easily exemplified in the instance of alumina and oil; if an acid solution of alumina be mixed with a solution of soap, which consists of oily matter and potassa, the oil and the alumina will unite and form a white powder, which will sink to the bottom of the fluid.

The extract from decomposing vegetable matter, when boiled with pipe-clay or chalk, forms a combination by which the vegetable matter is rendered more difficult of decomposition and of solution. Pure silica and siliceous sands have little action of this kind; and the soils which contain the most alumina and carbonate of lime are those which act with the greatest chemical energy in preserving manures. Such soils merit the appellation which is commonly given to them of rich soils; for the vegetable nourishment is long preserved in them, unless taken up by the organs of plants. Siliceous sands, on the contrary, deserve the term hungry, which is commonly applied to them; for the vegetable and animal matters they contain not being attracted by the earthy constituent parts of the soil, are more liable to be decomposed by the action of the atmosphere, or carried off from them by water.

In most of the black and brown rich vegetable moulds, the earths seem to be in combination with a peculiar extractive matter, afforded during the decomposition of vegetables: this is slowly taken up, or attracted from the earths by water, and appears to constitute a prime cause of the fertility of the soil.

The standard of fertility of soils for different plants must vary with the climate; and must be particularly influenced by the quantity of rain.

The power of soils to absorb moisture ought to be much greater in warm or dry countries than in cold and moist ones; and the quantity of clay, or vegetable or animal matter they contain, greater. Soils also on declivities ought to be more absorbent than in plains or in the bottom of valleys. Their productiveness likewise is influenced by the nature of the sub-soil, or the stratum on which they rest.

When soils are immediately situated upon a bed of rock or stone, they are much sooner rendered dry by evaporation, than where the sub-soil is of clay or marl: and one cause of the great fertility of some lands in the moist climate of Ireland is the proximity of the rocky strata to the soil.

A clayey sub-soil will sometimes be of material advantage to a sandy soil; and in this case it will retain moisture in such a manner as to be capable of supplying that lost by the earth above, in consequence of evaporation, or the consumption of it by plants.

A sandy, or gravelly sub-soil, often corrects the imperfections of too great a degree of absorbent power in the true soil.

In calcareous countries, where the surface is a species of marl, the soil is often found only a few inches above the limestone; and its fertility is not impaired by the proximity of the rock: though in a less absorbent soil, this situation would occasion barrenness; and the sandstone and limestone hills in Derbyshire and North Wales may be easily distinguished at a distance in summer by the different tints of the vegetation. The grass on the sandstone hills usually appears brown and burnt up; that on the limestone hills, flourishing and green.

In devoting the different parts of an estate to the necessary crops, it is perfectly evident from what has been said, that no general principle can be laid down, except when all the circumstances of the nature, composition, and situation of the soil and sub-soil are known.

The methods of cultivation, likewise, must be different for different soils. The same practice, which will be excellent in one case, may be destructive in another.

Deep ploughing may be a very profitable practice in a rich thick soil; and in a fertile shallow soil, situated upon cold clay or sandy sub-soil, it may be extremely prejudicial.

In a moist climate, where the quantity of rain that falls annually, equals from 40 to 60 inches, as in Lancashire, Cornwall, and some parts of Ireland, a siliceous sandy soil is much more productive than in dry districts; and in such situations, wheat and beans will require a less coherent and absorbent soil than in drier situations; and plants having bulbous roots will flourish in a soil containing as much as 14 parts out of 15 of sand.

Even the exhausting powers of crops will be influenced by like circumstances. In cases where plants cannot absorb sufficient moisture, they must take up more manure. And in Ireland, Cornwall, and the Western Highlands of Scotland, corn will exhaust less than in dry inland situations. Oats, particularly in dry climates, are impoverishing in a much higher degree than in moist ones.

Soils appear to have been originally produced in consequence of the decomposition of rocks and strata. It often happens, that soils are found in an unaltered state upon the rocks from which they were derived. It is easy to form an idea of the manner in which rocks are converted into soils, by referring to the instance of *soft granite*, or *porcelain granite*. This substance consists of three ingredients, quartz, feldspar, and mica. The quartz is almost pure siliceous earth, in a crystalline form. The feldspar and mica are very compounded substances; both contain silica, alumina, and oxide of iron: in the feldspar there is usually lime and potassa; in the mica, lime and magnesia.

When a granitic rock of this kind has been long exposed to the influence of air and water, the lime and the potassa contained in its constituent parts are acted upon by water or carbonic acid; and the oxide of iron, which is almost always in its least oxided state, tends to combine with more oxygen; the consequence is, that the felspar decomposes, and likewise the mica, but the first the most rapidly. The feldspar, which is as it were the cement of the stone, forms a fine clay: the mica partially decomposed, mixes with it as sand; and the undecomposed quartz appears as gravel, or sand of different degrees of fineness.

As soon as the smallest layer of earth is formed on the surface of a rock, the seeds of lichens, mosses, and other imperfect vegetables which are constantly floating in the atmosphere, and which have made it their resting-place, begin to vegetate; their death, decomposition, and decay, afford a certain quantity of organizable matter, which mixes with the earthy materials of the rock: in this improved soil more perfect plants are capable of subsisting; these in their turn, absorb nourishment from water and the atmosphere; and after perishing, afford new materials to those already provided: the decomposition of the rock still continues; and at length by such slow and gradual processes, a soil is formed in which even forest trees can fix their roots, and which is fitted to reward the labors of the cultivator.

In instances where successive generations of vegetables have grown upon a soil, unless part of their produce has been carried off by man, or consumed by animals, the vegetable matter increases in such a proportion that the soil approaches to a peat in its nature; and if in a situation where it can receive water from a higher district, it becomes spongy, and permeated with that fluid, and is gradually rendered incapable of supporting the nobler classes of vegetables.

Many peat-mosses seem to have been formed by the destruction of forests, in consequence of the imprudent use of the hatchet by the early cultivators of the country in which they exist: when the trees are felled in the outskirts of a wood, those in the interior exposed to the influence of the winds, and having been accustomed to shelter, become unhealthy, and die in their new situation; and their leaves and branches gradually decomposing, produce a stratum of vegetable matter. In many of the great bogs in Ireland and Scotland, the larger trees that are found in the out-skirts of them bear the marks of having been felled. In the interior few entire trees are found; and the cause is, probably, that they fell by gradual decay; and that the fermentation and decomposition of the vegetable matter was most rapid where it was in the greatest quantity.

Lakes and pools of water are sometimes filled up by the accumulation of the remains of aquatic plants; and in this case a sort of spurious peat is formed. The fermentation in these cases, however, seems to be of a different kind. Much more gaseous matter is evolved; and the neighborhood of morasses in which aquatic vegetables decompose is usually aguish and unhealthy; whilst that of the true peat, or peat formed on soils originally dry, is always salubrious.*

The earthy matter of peats is uniformly analogous to that of the stratum on which they repose; the plants which have formed them must have derived the earths that they contained from this stratum. Thus in Wiltshire and Berkshire, where the stratum below the peat is chalk, calcareous earth abounds in the ashes, and very little alumina and silica. They likewise contain much oxide of iron and gypsum, both of which may be derived from the decomposition of the pyrites, so abundant in chalk.

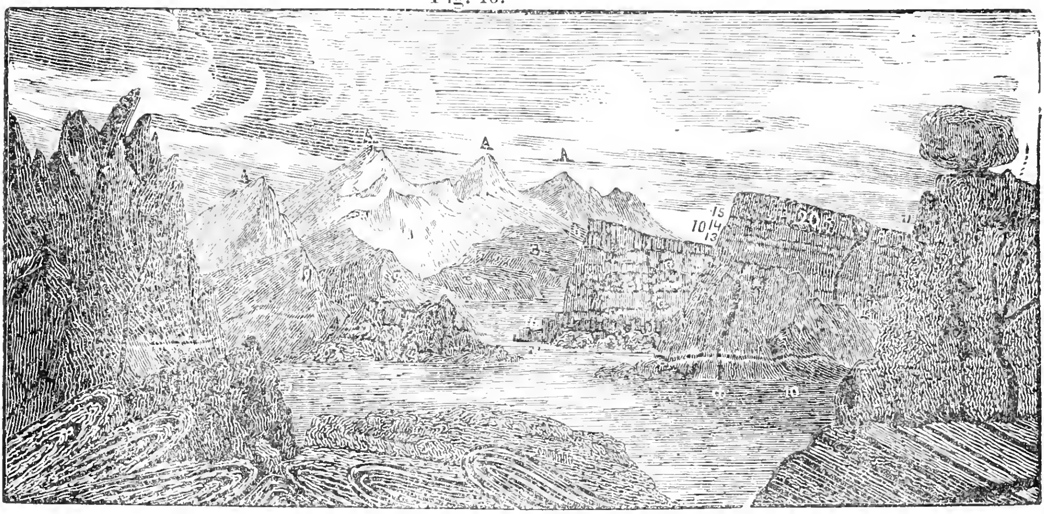
Different specimens of peat that I have burnt, from the granitic and schistose soils of different parts of these islands, have always given ashes, principally siliceous and aluminous; and a specimen of peat from the county of Antrim, gave ashes which afforded very nearly the same constituents as the great basaltic stratum of the county.

Poor and hungry soils, such as are produced from the decomposition of granitic and sandstone rocks, remain very often for ages with only a thin covering of vegetation. Soils from the decomposition of limestone, chalks, and basalts, are often clothed by nature with the perennial grasses; and afford, when ploughed up, a rich bed of vegetation for every species of cultivated plant.

Rocks and strata from which soils have been derived, and those which compose the more interior solid parts of the globe, are arranged in a certain order; and as it often happens that strata very different in their nature are associated together, and that the strata immediately beneath the soil contain materials which may be of use for improving it, a general view of the nature and position of rocks and strata in nature will not, I trust, be unacceptable to the scientific farmer.

Rocks are generally divided by geologists into

Fig. 16.



two grand divisions, distinguished by the names of *primary and secondary*.

The primary rocks are composed of pure crystalline matter, and contain no fragments of other rocks.

The secondary rocks, or strata, consist only partly of crystalline matter, contain fragments of other rocks or strata; often abound in remains of vegetables and marine animals; and sometimes contain the remains of land animals.

The primary rocks are generally arranged in large masses, or in layers, vertical or more or less inclined to the horizon.

The secondary rocks are usually disposed in strata or layers, parallel, or nearly parallel, to the horizon.

The number of primary rocks which are commonly observed in nature are eight.

First, *granite*, which, as has been mentioned, is composed of quartz, feldspar, and mica; when these bodies are arranged in regular layers in the rock, it is called *gneiss*.

Second, *micaceous schistus*, which is composed of quartz and mica, arranged in layers, which are usually curvilineal.

Third, *sienite*, which consists of the substance called hornblende and feldspar.

---

* In tropical climates no peat is formed; the temperature is too high. The dead vegetable matter rapidly decomposes, and is converted into gases; and this probably is one of the causes of these climates being so much more unhealthy and productive of malaria-fevers than temperate and cold climates.—J. D.

Fourth, *serpentine*, which is constituted by feldspar and a body named resplendent hornblende; and their separate crystals are often so small as to give the stone a uniform appearance: this rock abounds in veins of a substance called *steatite*, or *soap rock*.

Fifth, *porphyry*, which consists of crystals of feldspar, embedded in the same material; but usually of a different color.

Sixth, *granular marble*, which consists entirely of crystals of carbonate of lime; and which, when its color is white, and texture fine, is the substance used by statuaries.

Seventh, *chlorite schist*, which consists of chlorite, a green or gray substance, somewhat analogous to mica and feldspar.

Eighth, *quartzose rock*, which is composed of quartz in a granular form, sometimes united to small quantities of the crystalline elements, which have been mentioned as belonging to the other rocks.

The secondary rocks are more numerous than the primary; but twelve varieties include all that are usually found in these islands.

First, *grauwacke*, which consists of fragments of quartz, or chlorite schist, embedded in a cement, principally composed of feldspar.

Second, *siliceous sandstone*, which is composed of fine quartz or sand, united by a siliceous cement.

Third, *limestone*, consisting of carbonate of lime, more compact in its texture than in the granular marble; and often abounding in marine exuviæ.

Fourth, *aluminous schist* or *shale*, consisting of the decomposed materials of different rocks cemented by a small quantity of ferruginous or siliceous matter; and often containing the impressions of vegetables.

Fifth, *calcareous sandstone*, which is calcareous sand, cemented by calcareous matter.

Sixth, *ironstone*, formed of nearly the same materials as aluminous schist or shale; but containing a much larger quantity of oxide of iron.

Seventh, *basalt* or *whinstone*, which consists of feldspar and hornblende, with materials derived from the decomposition of the primary rocks; the crystals are generally so small as to give the rock a homogeneous appearance; and it is often disposed in very regular columns, having usually five or six sides.

Eighth, *bituminous* or *common coal*.

Ninth, *gypsum*, the substance so well known by that name, which consists of sulphate of lime; and often contains sand.

Tenth, *rock salt*.

Eleventh, *chalk*, which usually abounds in remains of marine animals, and contains horizontal layers of flints.

Twelfth, *plumb pudding stone*, consisting of pebbles cemented by a ferruginous or siliceous cement.

To describe more particularly the constituent parts of the different rocks and strata will be unnecessary; at any time, indeed, details on this subject are useless, unless the specimens are examined by the eye; and a close inspection and comparison of the different species will in a short time enable the most common observer to distinguish them.

The highest mountains in these islands, and indeed in the whole of the old continent, are constituted by granite; and this rock has likewise been found at the greatest depths to which the industry of man has yet been able to penetrate; micaceous schist is often found immediately upon granite; serpentine or marble upon micaceous schist; but the order in which the primary rocks are grouped together is various. Marble and serpentine are usually found uppermost; but granite, though it seems to form the foundation of the rocky strata of the globe, is yet sometimes discovered above micaceous schist.

The secondary rocks are always incumbent on the primary; the lowest of them is usually grauwacke; upon this limestone or sandstone is often found; coal generally occurs between sandstone or shale; basalt often exists above sandstone and limestone; rock salt almost always occurs associated with red sandstone and gypsum. Coal, basalt, sandstone, and limestone, are often arranged in different alternate layers, of no considerable thickness, so as to form a great extent of country. In a depth of less than 500 yards, 80 of these different alternate strata have been counted.

The veins which afford metallic substances, are fissures vertical or more or less inclined, filled with a material different from the rock in which they exist. This material is almost always crystalline; and usually consists of calcareous fluor spar, quartz, or heavy spar, either separate or together. The metallic substances are generally dispersed through, or confusedly mixed with these crystalline bodies. The veins in hard granite seldom afford much useful metal; but in the veins in soft granite and in gneiss tin, copper, and lead are found. Copper and iron are the only metals usually found in the veins in serpentine. Micaceous schist, sienite, and granular marble are seldom metalliferous rocks. Lead, tin, copper, iron, and many other metals, are found in the veins in chlorite schist. Grauwacke, when it contains few fragments, and exists in large masses, is often a metalliferous rock. The precious metals, likewise iron, lead, and antimony, are found in it: and sometimes it contains veins, or masses of *stone coal*, or coal free from bitumen. Limestone is the great metalliferous rock of the secondary family; and lead and copper are the metals most usually found in it. No metallic veins have ever been found in shale, chalk, or calcareous sandstone; and they are very rare in basalt and siliceous sandstone.*

In cases where veins in rocks are exposed to the atmosphere, indications of the metals they contain may be often gained from their superficial appearance. Whenever fluor spar is found in a vein, there is always strong reason to suspect that it is associated with metallic substances. A brown powder at the surface of a vein always indicates iron, and often tin; a pale yellow powder lead;

* Fig. 16. will give a general idea of the appearance and arrangement of rocks and veins.

and a green colour in a vein denotes the presence of copper.

It may not be improper to give a general description of the geological constitution of Great Britain and Ireland. Granite forms the great ridge of hills extending from Land's End through Dartmore into Devonshire. The highest rocky strata in Somersetshire are grauwacke and limestone. The Malvern hills are composed of granite, sienite, and porphyry. The highest mountains in Wales are chlorite schist, or grauwacke. Granite occurs at Mount Sorrel, in Leicestershire. The great range of the mountains in Cumberland and Westmoreland are prophyry, chlorite schist, and grauwacke; but granite is found as their western boundary. Throughout Scotland the most elevated rocks are granite, sienite, and micaceous schistus. No true secondary formations are found in South Britain, west of Dartmore; and no basalt south of the Severn. The chalk district extends from the western part of Dorsetshire to the eastern coast of Norfolk. The coal formations abound in the district between Glamorganshire and Derbyshire: and likewise in the secondary strata of Yorkshire, Durham, Westmorland, and Northumberland. Serpentine is found only in three places in Great Britain; near Cape Lizard in Cornwall, Portsoy in Aberdeenshire, and in Ayrshire. Black and gray granular marble is found near Padstow in Cornwall; and other colored primary marbles exist in the neighborhood of Plymouth. Colored primary marbles are abundant in Scotland: and white granular marble is found in the Isle of Sky, in Assynt, and on the banks of Loch Shin in Sutherland: the principal coal formations in Scotland are in Dumbartonshire, Ayrshire, Fifeshire, and on the banks of the Brora, in Sutherland. Secondary limestone and sandstone are found in most of the low countries north of the Mendip hills.

In Ireland there are five great associations of primary mountains; the mountains of Morne, in the county of Down; the mountains of Donegal; those of Mayo and Galway; those of Wicklow; and those of Kerry. The rocks composing the four first of these mountain chains are principally granite, gneiss, sienite, micaceous schist, and porphyry. The mountains of Kerry are chiefly constituted by granular quartz, and chlorite schist. Colored marble is found near Killarney; and white marble on the western coast of Donegal.

Limestone and sandstone are the common secondary rocks found south of Dublin. In Sligo, Roscommon, and Leitrim, limestone, sandstone, shale, ironstone, and bituminous coal are found. The secondary hills in these counties are of considerable elevation; and many of them have basaltic summits. The north coast of Ireland is principally basalt; this rock commonly reposes upon a white limestone, containing layers of flint, and the same fossils as chalk; but it is considerably harder than that rock. There are some instances, in this district, in which columnar basalt is found above sandstone and shale, alternating with coal. The stone-coal of Ireland is principally found in Kilkenny, associated with limestone and grauwacke.

It is evident from what has been said concerning the production of soils from rocks, that there must be at least as many varieties of soils as there are species of rocks exposed at the surface of the earth; in fact there are many more. Independent of the changes produced by cultivation and the exertions of human labor, the materials of strata have been mixed together and transported from place to place by various great alterations that have taken place in the system of our globe, and by the constant operation of water.

To attempt to class soils with scientific accuracy would be a vain labor; the distinctions adopted by farmers are sufficient for the purposes of agriculture; particularly if some degree of precision be adopted in the application of terms. The term sandy, for instance, should never be applied to any soil that does not contain at least $\frac{7}{8}$ of sand; sandy soils that effervesce with acids should be distinguished by the name of calcareous sandy soil, to distinguish them from those that are siliceous. The term clayey soil should not be applied to any land which contains less than $\frac{1}{6}$ of impalpable earthy matter, not considerably effervescing with acids: the word loam should be limited to soils containing at least one-third of impalpable earthy matter, copiously effervescing with acids. A soil, to be considered as peaty, ought to contain at least one-half of vegetable matter.

In cases where the earthy part of a soil evidently consists of a decomposed matter of one particular rock, a name derived from the rock may with propriety be applied to it. Thus, if a fine red earth be found immediately decomposing basalt, it may be denominated basaltic soil. If fragments of quartz and mica be found abundant in the materials of the soil, which is often the case, it may be denominated granitic soil; and the same principles may be applied to other like instances.

In general, the soils, the materials of which are the most various and heterogeneous, are those called alluvial, or which have been formed from the depositions of rivers; many of them are extremely fertile. I have examined some productive alluvial soils, which have been very different in their composition. The soil which has been mentioned before, as very productive, from the banks of the river Parret in Somersetshire, afforded me eight parts of finely divided earthy matter, and one part of siliceous sand; and an analysis of the finely divided matter gave the following results:—

360 parts of carbonate of lime.
25 — alumina.
20 — silica.
8 — oxide of iron.
19 — vegetable, animal, and saline matter.

A rich soil from the neighborhood of the Avon, in the valley of Evesham in Worcestershire, afforded me three-fifths of fine sand, and two-fifths of impalpable matter; the impalpable matter consisted of

35 Alumina.
41 Silica.
14 Carbonate of lime.
3 Oxide of iron.
7 Vegetable, animal, and saline matter.

A specimen of good soil from Tiviotdale, afforded five-sixths of fine siliceous sand, and one-sixth of impalpable matter; which consisted of

41 Alumina.
42 Silica.
4 Carbonate of lime.
5 Oxide of iron.
8 Vegetable, animal, and saline matter.

A soil yielding excellent pasture from the valley of the Avon, near Salisbury, afforded one-eleventh of coarse silicеous sand; and the finely divided matter consisted of

7 Alumina.
14 Silica.
63 Carbonate of lime.
2 Oxide of iron.
14 Vegetable, animal, and saline matter.

In all these instances the fertility seems to depend upon the state of division, and mixture of the earthy materials and the vegetable and animal matter; and may be easily explained on the principles which I have endeavored to elucidate in the preceding part of this Lecture.

In ascertaining the composition of steril soils with a view to their improvement, any particular ingredient which is the cause of their unproductiveness, should be particularly attended to; if possible. they should be compared with fertile soils in the same neighborhood, and in similar situations, as the difference of the composition may, in many cases, indicate the most proper methods of improvement. If on washing a steril soil it is found to contain the salt of iron, or any acid matter, it may be ameliorated by the application of quick-lime. A soil of good apparent texture from Lincolnshire, was put into my hands by Sir Joseph Banks as remarkable for sterility. On examining it, I found that it contained sulphate of iron: and I offered the obvious remedy of top-dressing with lime, which converts the sulphate into a manure If there be an excess of calcareous matter in the soil, it may be improved by the application of sand, or clay. Soils too abundant in sand are benefited by the use of clay or marl, or vegetable matter. A field belonging to Sir Robert Vaughan at Nannau, Merionethshire, the soil of which was a light sand, was much burnt up in the summer of 1805; I recommended to that gentleman the application of peat as a top-dressing. The experiment was attended with immediate good effects; and Sir Robert has informed me, that the benefit was permanent. A deficiency of vegetable or animal matter must be supplied by manure. An excess of vegetable matter is to be removed by burning, or to be remedied by the application of earthy materials. The improvement of peats, or bogs, or marsh lands, must be preceded by draining; stagnant water being injurious to all the nutritive classes of plants. Soft black peats, when drained, are often made productive by the mere application of sand or clay as a top-dressing. When peats are acid, or contain ferruginous salts, calcareous matter is absolutely necessary in bringing them into cultivation. When they abound in the branches and roots of trees, or when their surface entirely consists of living vegetables, the wood or the vegetables must either be carried off, or be destroyed by burning. In the last case their ashes afford earthy ingredients, fitted to improve the texture of the peat.

The best natural soils are those of which the materials have been derived from different strata; which have been minutely divided by air and water, and are intimately blended together: and in improving soils artificially, the farmer cannot do better than imitate the processes of nature.

The materials necessary for the purpose are seldom far distant: coarse sand is often found immediately on chalk; and beds of sand and gravel are common below clay. The labor of improving the texture or constitution of the soil is repaid by a great permanent advantage; less manure is required, and its fertility insured. And capital laid out in this way secures for ever the productiveness, and consequently the value, of the land.

LECTURE V.

ON THE NATURE AND CONSTITUTION OF THE ATMOSPHERE, AND ITS INFLUENCE ON VEGETABLES. OF THE GERMINATION OF SEEDS. OF THE FUNCTIONS OF PLANTS IN THEIR DIFFERENT STAGES OF GROWTH; WITH A GENERAL VIEW OF THE PROGRESS OF VEGETATION.

The constitution of the atmosphere has been already generally referred to in the preceding Lectures. Water, carbonic acid gas, oxygen, and azote, have been mentioned as the principal substances composing it; but more minute inquiries respecting their nature and agencies are necessary to afford correct views of the uses of the atmosphere in vegetation.

On these inquiries I now propose to enter; the pursuit of them, I hope, will offer some objects of practical use in farming; and present some philosophical illustrations of the manner in which plants are nourished, their organs unfolded, and their functions developed.

If some of the salt called muriate of lime that has been just heated red be exposed to the air, even in the driest and coldest weather, it will increase in weight and become moist; and in a certain time will be converted into a fluid. If put into a retort and heated, it will yield pure water; will gradually recover its pristine state; and, if heated red, its former weight: so that it is evident that the water united to it was derived from the air. And that it existed in the air in an invisible and elastic form, is proved by the circumstance, that if a given quantity of air be exposed to the salt, its volume and weight will diminish, provided the experiment be correctly made.

The quantity of water which exists in air, as vapor, varies with the temperature. In proportion as the weather is hotter, the quantity is greater. At 50° of Fahrenheit air contains about $\frac{1}{50}$ of its volume of vapor; and as the specific gravity of vapor is to that of air nearly as 10 to 15, this is about $\frac{1}{75}$ of its weight.

At 100°, supposing that there is a free communication with water, it contains about $\frac{1}{14}$ parts in volume, or $\frac{1}{21}$ in weight. It is the condensation of vapor by diminution of the temperature of the atmosphere, which is probably the principal cause of the formation of clouds, and of the deposition of dew, mist, snow, or hail.

The power of different substances to absorb aqueous vapor from the atmosphere by cohesive attraction was discussed in the last Lecture. The leaves of living plants appear to act upon the vapor likewise in its elastic form, and to absorb it. Some vegetables increase in weight from this cause, when suspended in the atmosphere and unconnected with the soil; such are the houseleek, and different species of the aloe. In very intense heats, and when the soil is dry, the life of plants seems to be preserved by the absorbent power of their leaves: and it is a beautiful circumstances in the economy of nature, that aqueous vapor is most abundant in the atmosphere when it is most needed for the purposes of life: and that when other sources of its supply are cut off, this is most copious.

The compound nature of water has been referred to. It may be proper to mention the experimental proofs of its decomposition into, and composition from, oxygen and hydrogen.

If the metal called potassium be exposed in a glass tube to a small quantity of water, it will act upon it with great violence; elastic fluid will be disengaged, which will be found to be hydrogen; and the same effects will be produced upon the potassium, as if it had absorbed a small quantity of oxygen; and the hydrogen disengaged, and the oxygen added to the potassium, are in weight as 2 to 15; and if two in volume of hydrogen, and one in volume of oxygen, which have the weights of 2 and 15, be introduced into a close vessel, and an electrical spark passed through them, they will inflame and condense into 17 parts of pure water.

It is evident from the statements given in the third lecture, that water forms by far the greatest part of the sap of plants; and that this substance, or its elements, enters largely into the constitution of their organs and solid productions.

Water is absolutely necessary to the economy of vegetation in its elastic and fluid state; and it is not devoid of use even in its solid form. Snow and ice are bad conductors of heat; and when the ground is covered with snow, or the surface of the soil or of water is frozen, the roots or bulbs of the plants beneath are protected by the congealed water from the influence of the atmosphere, the temperature of which in northern winters is usually very much below the freezing point; and this water becomes the first nourishment of the plant in early spring. The expansion of water during its congelation, at which time its volume increases one-twelfth, and its contraction of bulk during a thaw, tend to pulverise the soil; to separate its parts from each other, and to make it more permeable to the influence of the air.

If a solution of lime in water be exposed to the air, a pellicle will speedily form upon it, and a solid matter will gradually fall to the bottom of the water, and in a certain time the water will become tasteless; this is owing to the combination of the lime, which was dissolved in the water, with carbonic acid gas which existed in the atmosphere, as may be proved by collecting the film and the solid matter, and igniting them strongly in a little tube of platina or iron; they will give off carbonic acid gas, and will become quick-lime, which, added to the same water, will again bring it to the state of lime-water.

The quantity of carbonic acid gas in the atmosphere is very small. It is not easy to determine it with precision, and it must differ in different situations; but where there is a free circulation of air, it is probably never more than one-five hundredth, nor less than one-eight hundredth of the volume of air. Carbonic acid gas is nearly one-third heavier than the other elastic parts of the atmosphere in their mixed state: hence, at first view, it might be supposed that it would be most abundant in the lower regions of the atmosphere; but unless it has been immediately produced at the surface of the earth in some chemical process, this does not seem to be the case: elastic fluids of different specific gravities have a tendency to equable mixture by a species of attraction, and the different parts of the atmosphere are constantly agitated and blended together by winds or other causes. De Saussure found lime-water precipitated on Mount Blanc, the highest point of land in Europe; and carbonic acid gas has been always found, apparently in due proportion, in the air brought down from great heights in the atmosphere by aërostatic adventurers.

The experimental proofs of the composition of carbonic acid gas are very simple. If 13 grains of well burnt charcoal be inflamed by a burning-glass in 100 cubical inches of oxygen gas, the charcoal will entirely disappear; and, provided the experiment be correctly made, all the oxygen, except a few cubical inches, will be found converted into carbonic acid; and, what is very remarkable, the volume of the gas is not changed. On this last circumstance it is easy to found a correct estimation of the quantity of pure charcoal and oxygen in carbonic acid gas: the weight of 100 cubical inches of carbonic acid gas is to that of 100 cubical inches of oxygen gas, as 47 to 34: so that 47 parts in weight of carbonic acid gas must be composed of 34 parts of oxygen and 13 of charcoal, which correspond with the numbers given in the second lecture.

Carbonic acid is easily decomposed by heating potassium in it; the metal combines with the oxygen, and the charcoal is deposited in the form of a black powder.

The principal consumption of the carbonic acid in the atmosphere, seems to be in affording nourishment to plants; and some of them appear to be supplied with carbon chiefly from this source.

Carbonic acid gas is formed during fermentation, combustion, putrefaction, respiration, and a number of operations taking place upon the surface of the earth; and there is no other process known in nature by which it can be destroyed but by vegetation.

After a given portion of air has been deprived of aqueous vapor and carbonic acid gas, it appears little altered in its properties; it supports combustion and animal life. There are many modes of separating its principal constituents, oxygen, and azote, from each other. A simple one is by burning phosphorus in a confined volume of air: this absorbs the oxygen and leaves the azote; and 100 parts in volume of air, in which phosphorus has been burnt, yield 79 parts of azote; and by mixing this azote with 21 parts of fresh oxygen gas, artificially procured, a substance having the original characters of air is produced. To procure pure oxygen from air, quicksilver may be kept heated in it, at about 600°, till it becomes a red powder: this powder, when ignited, will be restored to the state of quicksilver by giving off oxygen.

Oxygen is necessary to some functions of vegetables, but its great importance in nature is in its relation to the economy of animals. It is absolutely necessary to their life. Atmospheric air taken into the lungs of animals, or passed in solution in water through the gills of fishes, loses oxygen; and for the oxygen lost, about an equal volume of carbonic acid appears.

The effects of azote in vegetation are not distinctly known. As it is found in some of the products of vegetation, it may be absorbed by certain plants from the atmosphere. It prevents the action of oxygen from being too energetic, and serves as a medium in which the more essential parts of the air act: nor is this circumstance unconformable to the analogy of nature; for the elements most abundant on the solid surface of the globe, are not those which are the most essential to the existence of the living beings belonging to it.

The action of the atmosphere on plants differs at different periods of their growth, and varies with the various stages of the developement and decay of their organs. Some general idea of its influence may have been gained from circumstances already mentioned: I shall now refer to it more particularly, and endeavor to connect it with a general view of the progress of vegetation.

If a healthy seed be moistened and exposed to air at a temperature not below 45°, it soon germinates; it shoots forth a plume which rises upwards, and a radicle which descends.

If the air be confined, it is found that in the process of germination the oxygen, or a part of it, is absorbed. The azote remains unaltered; no carbonic acid is taken away from the air; on the contrary, some is added.

Seeds are incapable of germinating, except when oxygen is present. In the exhausted receiver of the air-pump, in pure azote, in pure carbonic acid, when moistened they swell, but do not vegetate; and if kept in these gases, lose their living powers, and undergo putrefaction.

If a seed be examined before germination, it will be found more or less insipid, at least not sweet; but after germination it is always sweet. Its coagulated mucilage, or starch, is converted into sugar in the process; a substance difficult of solution is changed into one easily soluble; and the sugar carried through the cells or vessels of the cotyledons, is the nourishment of the infant plant. It is easy to understand the nature of the change, by referring to the facts mentioned in the third lecture; and the production of carbonic acid renders probable the idea, that the principal chemical difference between sugar and mucilage depends upon the sugar containing a larger proportion of the elements of water, and upon a slight difference in the proportions of their carbon.

The absorption of oxygen by the seed in germination, has been compared to its absorption in producing the evolution of fœtal life in the egg; but this analogy is only remote. All animals, from the most to the least perfect classes, require a supply of oxygen.* From the moment the heart begins to pulsate till it ceases to beat, the aëration of the blood is constant, and the function of respiration invariable; carbonic acid is given off in the process, but the chemical change produced in the blood is unknown; nor is there any reason to suppose the formation of any substance similar to sugar. In the production of a plant from a seed, some reservoir of nourishment is needed before the root can supply sap; and this reservoir is the cotyledon, in which it is stored up in an insoluble form, and protected, if necessary, during the winter, and rendered soluble by agents which are constantly present on the surface. The change of starch into sugar, connected with the absorption of oxygen, may be rather compared to a process of fermentation than to that of respiration; it is a change effected upon unorganized matter, and can be artificially imitated; and in most of the chemical changes that occur when vegetable compounds are exposed to air, oxygen is absorbed, and carbonic acid formed or evolved.

It is evident, that in all cases of tillage the seeds should be sown so as to be fully exposed to the influence of the air. And one cause of the unproductiveness of cold clayey adhesive soils is, that the seed is coated with matter impermeable to air.

In sandy soils the earth is always sufficiently penetrable by the atmosphere; but in clayey soils there can scarcely be too great a mechanical division of parts in the process of tillage. Any seed not fully supplied with air, always produces a weak and diseased plant.

The process of malting, which has been already referred to, is merely a process in which germination is artificially produced; and in which the starch of the cotyledon is changed into sugar; which sugar is afterwards, by fermentation, converted into spirit.

It is very evident from the chemical principles of germination, that the process of malting should be carried on no further than to produce the sprouting of the radicle, and should be checked as soon as this has made its distinct appearance. If it is pushed to such a degree as to occasion the perfect developement of the radicle and the plume, a considerable quantity of saccharine matter will have been consumed in producing their expansion, and there will be less spirit formed in fermentation, or produced in distillation.

As this circumstance is of some importance, I made in October, 1806, an experiment relating to it. I ascertained by the action of alcohol, the relative proportions of saccharine matter in two equal quantities of the same barley; in one of which the germination had proceeded so far as to occasion a protrusion of the radicle to nearly a-quarter of an inch beyond the grain in most of the specimens, and in the other of which it had been checked before the radicle was a line in length; the quantity of sugar afforded by the last was to that in the first nearly as six to five.

The saccharine matter in the cotyledons at the time of their change into seed-leaves, renders them exceedingly liable to the attacks of insects:

* The impregnated eggs of insects, and even of fishes, do not produce young ones, unless they are supplied with air, that is, unless the fœtus can respire. I have found that the eggs of moths did not produce larvæ when confined in pure carbonic acid; and when they were exposed in common air, the oxygen partly disappeared, and carbonic acid was formed. The fish in the egg or spawn gains its oxygen from the air dissolved in water; and those fishes that spawn in spring and summer in still water, such as the pike, carp, perch, and bream, deposit their eggs upon subaquatic vegetables, the leaves of which, in performing their healthy functions, supply oxygen to the water. The fish that spawn in winter, such as the salmon and trout, seek spots where there is a constant supply of fresh water, as near the sources of streams as possible, and in the most rapid currents, where all stagnation is prevented, and where the water is saturated with air, to which it has been exposed during its deposition from clouds. It is the instinct leading these fish to seek a supply of air for their eggs which carries them from seas or lakes into the mountain country, which induces them to move against the stream, and to endeavor to overleap weirs, mill-dams, and cataracts.

this principle is at once a nourishment of plants and animals, and the greatest ravages are committed upon crops in this first stage of their growth.

The turnip fly, an insect of the colyoptera genus, fixes itself upon the seed-leaves of the turnip at the time that they are beginning to perform their functions; and when the rough leaves of the plume are thrown forth, it is incapable of injuring the plant to any extent.

Several methods have been proposed for destroying the turnip fly, or for preventing it from injuring the crop. It has been proposed to sow radish-seed with the turnip seed, on the idea that the insect is fonder of the seed-leaves of the radish than those of the turnip: it is said that this plan has not been successful, and that the fly feeds indiscriminately on both.

There are several chemical menstrua which render the process of germination much more rapid, when the seeds have been steeped in them. As in these cases the seed-leaves are quickly produced, and more speedily perform their functions, I proposed it as a subject of experiment to examine whether such menstrua might not be useful in raising the turnip more speedily to that state in which it would be secure from the fly; but the result proved that the practice was inadmissible; for seeds so treated, though they germinated much quicker, did not produce healthy plants, and often died soon after sprouting.

I steeped radish-seeds in September, 1807, for 12 hours, in a solution of chlorine, and similar seeds in very diluted nitric acid, in very diluted sulphuric acid, in weak solution of oxysulphate of iron, and some in common water. The seeds in solutions of chlorine and oxysulphate of iron threw out the germ in two days, those in nitric acid in three days, in sulphuric acid in five, and those in water in seven days. But in the cases of premature germination, though the plume was very vigorous for a short time, yet it became at the end of a fortnight weak and sickly; and at that period less vigorous in its growth than the sprouts which had been naturally developed, so that there can be scarcely any useful application of these experiments. Too rapid growth and premature decay seem invariably connected in organized structures: and it is only by following the slow operations of natural causes, that we are capable of making improvements.

There is a number of chemical substances which are very offensive and even deadly to insects, which do not injure, and some of which even assist vegetation. Several of these mixtures have been tried with various success, a mixture of sulphur and lime, which is very destructive to slugs, does not prevent the ravages of the fly on the young turnip crop. His Grace the Duke of Bedford, at my suggestion, was so good as to order the experiment to be tried on a considerable scale at Woburn farm: the mixture of lime and sulphur was strewed over one part of a field sown with turnips; nothing was applied to the other part, but both were attacked nearly in the same manner by the fly.

Mixtures of soot and quick-lime, and urine and quick-lime, will probably be more efficacious. The volatile alkali given off by these mixtures is offensive to insects; and they afford nourishment to the plant. Mr. T. A. Knight* informs me, that he has tried the method by ammoniacal fumes with success; but more extensive trials are necessary to establish its general efficacy. It may, however, be safely adopted; for if it should fail in destroying the fly, it will at least be a useful manure to the land.

After the roots and leaves of the infant plant are formed, the cells and tubes throughout its structure become filled with fluid, which is usually supplied from the soil, and the function of nourishment is performed by the action of its organs upon the external elements. The constituent parts of the air are subservient to this process; but, as it might be expected, they act differently under different circumstances.

When a growing plant, the roots of which are supplied with proper nourishment, is exposed in the presence of solar light to a given quantity of atmospherical air, containing its due proportion of carbonic acid, the carbonic acid after a certain time is destroyed, and a certain quantity of oxygen is found in its place. If new quantities of carbonic acid gas be supplied, the same result occurs; so that carbon is added to plants from the air by the process of vegetation in sunshine; and oxygen is added to the atmosphere.

This circumstance is proved by a number of experiments made by Drs. Priestley, Ingenhousz, and Woodhouse, and M. T. de Saussure; many

---

* Mr. Knight has been so good as to furnish me with the following note on this subject.

"The experiment which I tried the year before last, and last year, to preserve turnips from the fly, has not been sufficiently often repeated to enable me to speak with any degree of decision; and last year all my turnips succeeded perfectly well. In consequence of your suggestion, when I had the pleasure to meet you some years ago at Holkham, that lime slaked with urine might possibly be found to kill, or drive off, the insects from a turnip crop, I tried that preparation in mixture with three parts of soot, which was put into a small barrel, with gimlet holes round it, to permit a certain quantity of the composition, about four bushels to an acre, to pass out, and to fall into the drills with the turnip seeds. Whether it was by affording highly stimulating food to the plant, or giving some flavor which the flies did not like, I cannot tell; but in the year 1811, the adjoining rows were eaten away, and those to which the composition was applied, as above described, were scarcely at all touched. It is my intention in future to drill my crop in, first, with the composition on the top of the ridge; and then to sow at least a pound of seed, broad-cast, over the whole ground. The expense of this will be very trifling, not more than 2s. per acre; and the horse-hoe will instantly sweep away all the supernumeraries between the rows, should those escape the flies, to which, however, they will be chiefly attracted; because it will always be found that those insects prefer turnips growing in poor to those in rich ground. One advantage seems to be the acceleration given to the growth of the plants, by the highly stimulative effects of the food they instantly receive, as soon as their growth commences, and long before their radicals have reached the dung. The directions above given apply only to turnips sowed upon ridges, with the manure immediately under them; and I am quite certain, that in all soils turnips should be thus cultivated. The close vicinity of the manure, and the consequent short time required to carry the food into the leaf, and return the organizable matter to the roots, are, in my hypothesis, points of vast importance; and the results in practice are correspondent."

of which I have repeated with similar results. The absorption of carbonic acid gas and the production of oxygen are performed by the leaf; and leaves recently separated from the tree effect the change, when confined in portions of air containing carbonic acid; and absorb carbonic acid and produce oxygen, even when immersed in water holding carbonic acid in solution.

The carbonic acid is probably absorbed by the fluids in the cells of the green or parenchymatous part of the leaf; and it is from this part that oxygen gas is produced during the presence of light. M. Sennebier found that the leaf, from which the epidermis was stripped off, continued to produce oxygen when placed in water containing carbonic acid gas, and the globules of air rose from the denuded parenchyma; and it is shown both from the experiments of Sennebier and Woodhouse, that the leaves most abundant in parenchymatous parts produce most oxygen in water impregnated with carbonic acid.

Some few plants* will vegetate in an artificial atmosphere, consisting principally of carbonic acid, and many will grow for some time in air containing from one-half to one-third; but they are not so healthy as when supplied with smaller quantities of this elastic substance.

Plants exposed to light have been found to produce oxygen gas in an elastic medium and in water containing no carbonic acid gas; but in quantities much smaller than when carbonic acid gas was present.

In the dark, no oxygen gas is produced by plants, whatever be the elastic medium to which they are exposed; and no carbonic acid absorbed. In most cases, on the contrary, oxygen gas, if it be present, is absorbed, and carbonic acid gas is produced.

In the changes that take place in the composition of the organized parts it is probable that saccharine compounds are principally formed during the absence of light: gum, woody fibre, oils, and resins, during its presence; and the evolution of carbonic acid gas, or its formation during the night, may be necessary to give greater solubility to certain compounds in the plant. I once suspected that all the carbonic acid gas, produced by plants in the night, or in shade, might be owing to the decay of some part of the leaf, or epidermis; but the recent experiments of Mr. D. Ellis are opposed to this idea; and I found that a perfectly healthy plant of celery, placed in a given portion of air for a few hours only, occasioned a production of carbonic acid gas, and an absorption of oxygen.

Some persons have supposed that plants exposed in the free atmosphere to the vicissitudes of sunshine and shade, light and darkness, consume more oxygen than they produce, and that their permanent agency upon air is similar to that of animals; and this opinion is espoused by the writer on the subject I have just quoted, in his ingenious researches on vegetation. But all experiments brought forwards in favor of this idea, and particularly his experiments, have been made under circumstances unfavorable to accuracy of result. The plants have been confined and supplied with food in an unnatural manner; and the influence of light upon them has been very much diminished by the nature of the media through which it passed. Plants confined in limited portions of atmospheric air soon become diseased; their leaves decay, and by their decomposition they rapidly destroy the oxygen of the air. In some of the early experiments of Dr. Priestley, before he was acquainted with the agency of light upon leaves, air that had supported combustion and respiration, was found purified by the growth of plants when they were exposed in it for successive days and nights; and his experiments are the more unexceptionable, as the plants, in many of them, grew in their natural states; and shoots, or branches from them, only were introduced through water into the confined atmosphere.

I have made some few researches on this subject, and I shall describe their results. On the 12th of July, 1800, I placed a turf four inches square, clothed with grass, principally meadow fox-tail, and white clover, in a porcelain dish, standing in a shallow tray filled with water; I then covered it with a jar of flint glass, containing 380 cubical inches of common air in its natural state. It was exposed in a garden, so as to be liable to the same changes with respect to light as in the common air. On the 20th of July the results were examined. There was an increase of the volume of the gas, amounting to fifteen cubical inches; but the temperature had changed from 64° to 71°; and the pressure of the atmosphere, which on the 12th had been equal to the support of 30.1 inches of mercury, was now equal to that of 30.2. Some of the leaves of the white clover, and of the fox-tail were yellow, and the whole appearance of the grass less healthy than when it was first introduced. A cubical inch of the gas, agitated in lime-water, gave a slight turbidness to the water; and the absorption was not quite $\frac{1}{150}$ of its volume: 100 parts of the residual gas exposed to a solution of green sulphate of iron, impregnated with nitrous gas, a substance which rapidly absorbs oxygen from air, occasioned a diminution to 80 parts; 100 parts of the air of the garden occasioned a diminution to 79 parts.

If the results of this experiment be calculated upon, it will appear that the air had been slightly deteriorated by the action of the grasses. But the weather was unusually cloudy during the progress of the experiment; the plants had not been supplied in a natural manner with carbonic acid gas; and the quantity formed during the night, and by the action of the faded leaves, must have been partly dissolved by the water; and that this was actually the case, I proved by pouring lime-water into the water, when an immediate precipitation was occasioned. The increase of azote I am inclined to attribute to common air disengaged from the water.

The following experiment I consider as conducted under circumstances more analogous to those existing in nature. A turf four inches square, from an irrigated meadow, clothed with common meadow grass, meadow fox-tail grass, and vernal meadow grass, was placed in a porcelain dish, which swam on the surface of water impregnated with carbonic acid gas. A vessel of thin flint glass, of the capacity of 230 cubical inches, having a funnel furnished with a stop-cock inserted in the top, was made to cover the grass; and the apparatus was exposed in an open place;

* I found the Arenaria tenuifolia to produce oxygen in carbonic acid, which was nearly pure.

a small quantity of water was daily supplied to the grass by means of the stop-cock.* Every day likewise a certain quantity of water was removed by a syphon, and water saturated with carbonic acid gas was supplied in its place; so that it may be presumed that a small quantity of carbonic acid gas was constantly present in the receiver. On the 7th of July, 1807, the first day of the experiment, the weather was cloudy in the morning, but fine in the afternoon; the thermometer at 67, the barometer 30.2: towards the evening of this day a slight increase of the gas was perceived: the next three days were bright; but in the morning of the 11th the sky was clouded; a considerable increase of the volume of the gas was now observed: the 12th was cloudy, with gleams of sunshine; there was still an increase, but less than in the bright days: the 13th was bright. About nine o'clock A. M. on the 14th, the receiver was quite full; and considering the original quantity in the jar, it must have been increased by at least 30 cubical inches of elastic fluid: at times during this day globules of gas escaped. At ten on the morning of the 15th, I examined a portion of the gas; it contained less than $\frac{1}{50}$ of carbonic acid gas; 100 parts of it exposed to the impregnated solution left only 75 parts; so that the air was four per cent. purer than the air of the atmosphere.

I shall detail another similar experiment made with equally decisive results. A shoot from a vine, having three healthy leaves belonging to it, attached to its parent tree, was bent so as to be placed under the receiver which had been used in the last experiment; the water confining the common air was kept in the same manner impregnated with carbonic acid gas: the experiment was carried on from August 6th, till August 14th, 1807; during this time, though the weather had been generally clouded, and there had been some rain, the volume of elastic fluid continued to increase. Its quality was examined on the morning of the 15th; it contained $\frac{1}{17}$ of carbonic acid gas, and 100 parts of it afforded 23.5 of oxygen gas.

These facts confirm the popular opinion, that when the leaves of vegetables perform their healthy functions, they tend to purify the atmosphere in the common variations of weather, and changes from light to darkness.

In germination, and at the time of the decay of the leaf, oxygen must be absorbed; but when it is considered how large a part of the surface of the earth is clothed with perennial grasses, and that half of the globe is always exposed to the solar light it appears by far the most probable opinion, that more oxygen is produced than consumed during the process of vegetation; and that it is this circumstance which is the principal cause of the uniformity of the constitution of the atmosphere.

Animals produce no oxygen gas during the exercise of any of their functions, and they are constantly consuming it; but the extent of the animal, compared to that of the vegetable kingdom, is very small; and the quantity of carbonic acid gas produced in respiration, and in various processes of combustion and fermentation, bears a proportion extremely minute to the whole volume of the atmosphere: if every plant during the progress of its life makes a very small addition of oxygen to the air, and occasions a very small consumption of carbonic acid, the effect may be conceived adequate to the wants of nature.

It may occur as an objection to these views, that if the leaves of plants purify the atmosphere, towards the end of autumn, and through the winter, and early spring, the air in our climates must become impure, the oxygen in it diminish, and the carbonic acid gas increase, which is not the case; but there is a very satisfactory answer to this objection. The different parts of the atmosphere are constantly mixed together by winds, which, when they are strong, move at the rate of from 60 to 100 miles in an hour. In our winter, the southwest gales convey air which has been purified by the vast forests and savannahs of South America, and which passing over the ocean, arrives in an uncontaminated state. The storms and tempests which often occur at the beginning, and towards the middle of our winter, and which generally blow from the same quarter of the globe, have a salutary influence. By constant agitation and motion, the equilibrium of the constituent parts of the atmosphere is preserved; it is fitted for the purposes of life; and those events which the superstitious formerly referred to the wrath of Heaven, or the agency of evil spirits, and in which they saw only disorder and confusion, are demonstrated, by science, to be ministrations of Divine Intelligence, and connected with the order and harmony of our system.

I have reasoned, in a former part of this lecture, against the close analogy which some persons have assumed between the absorption of oxygen and the formation of carbonic acid gas in germination, and in the respiration of the fœtus. Similar arguments will apply against the pursuit of this analogy, between the functions of the leaves of the adult plant, and those of the lungs of the adult animal. Plants grow vigorously only when supplied with light; and most species die if deprived of it. It cannot be supposed that the production of oxygen from the leaf, which is known to be connected with its natural color, is the exertion of a diseased function, or that it can acquire carbon in the day-time, when it is in most vigorous growth, when the sap is rising, when all its powers of obtaining nourishment are exerted, merely for the purpose of giving it off again in the night, when its leaves are closed, when the motion of the sap is imperfect, and when it is in a state approaching to that of quiescence. Many plants that grow upon rocks, or soils, containing no carbonic matter, can only be supposed to acquire their charcoal from the carbonic acid gas in the atmosphere; and the leaf may be considered at the same time as an organ of absorption, and an organ in which the sap may undergo different chemical changes.

When pure water only is absorbed by the roots of plants, the fluid, in passing into the leaves, will probably have greater power to absorb carbonic acid from the atmosphere. When the water is saturated with carbonic acid gas, some of this substance, even in the sunshine, may be given off by the leaves; but a part of it likewise will be always decomposed, which has been proved by the experiments of M. Sennebier.

When the fluid taken up by the roots of plants contains much carbonaceous matter, it is probable that plants may give off carbonic acid from their leaves even in the sunshine. In short, the func-

* See Fig. 17.

Fig. 17.

tion of the leaf must vary according to the composition of the sap passing through it, and according to the nature of the products which are formed from it. When sugar is to be produced, as in early spring at the time of the developement of buds and flowers, it is probable that less oxygen will be given off than at the time of the ripening of the seed, when starch, or gums, or oils, are formed; and the process of ripening the seed usually takes place when the agency of the solar light is most intense. When the acid juices of fruits become saccharine in the natural process of vegetation, more oxygen, there is every reason to believe, must be given off, or newly combined, than at other times; for, as it was shown in the third lecture, all the vegetable acids contain more oxygen than sugar. It appears probable, that in some cases in which oily and resinous bodies are formed in vegetation, water may be decomposed; its oxygen set free, and its hydrogen absorbed.

Mr. Berard, of Montpellier, has shown that fruits in ripening convert the oxygen of the air into carbonic acid; and that the process of ripening may be suspended by the exclusion of the fruit from oxygen gas, and that it will go on again after a certain interval of time. Unripe peaches, plums, and apricots, may be preserved in close bottles, filled with air deprived of oxygen, for from twenty days to a month; and pears and apples about three months, when they will afterward ripen perfectly by exposure to air.

I have already mentioned, that some plants produce oxygen in pure water. Dr. Ingenhousz found this to be the case with species of the confervæ. I have tried the leaves of many plants, particularly those that produce volatile oils. When such leaves are exposed in water saturated with oxygen gas, oxygen is given off in the solar light; but the quantity is very small, and always limited; nor have I been able to ascertain with certainty whether the vegetative powers of the leaf were concerned in the operation, though it seems probable. I obtained a considerable quantity of oxygen in an experiment made fifteen years ago, in which vine leaves were exposed to pure water; but on repeating the trials often since, the quantities have always been very much smaller. I am ignorant whether this difference is owing to the peculiar state of the leaves, or to some confervæ which might have adhered to the vessel, or to other sources of fallacy.

The most important and most common products of vegetables, mucilage, starch, sugar, and woody fibre, are composed of water, or the elements of water in their due proportion, and charcoal; and these, or some of them, exist in all plants: and the decomposition of carbonic acid, and the combination of water in vegetable structures, are processes which must occur almost universally.

When glutinous and albuminous substances exist in plants, the azote they contain may be suspected to be derived from the atmosphere: but no experiments have been made which prove this; they might easily be instituted upon mushrooms and funguses.

In cases in which buds are formed, or shoots thrown forth from roots, oxygen appears to be uniformly absorbed, as in the germination of seeds. I exposed a small potato, moistened with common water, to 24 cubical inches of atmospherical air, at a temperature of 59°. It began to throw forth a shoot on the third day; when it was half an inch long I examined the air; nearly a cubical inch of oxygen was absorbed, and about three-fourths of a cubical inch of carbonic acid formed. The juices in a shoot separated from the potato had a sweet taste; and the absorption of oxygen, and the production of carbonic acid, were probably connected with the conversion of a portion of starch into sugar. When potatoes that have been frozen are thawed, they become sweet; probably oxygen is absorbed in this process; if so, the change may be prevented by thawing them out of the contact of air; under water, for instance, that has been recently boiled.

In the tillering of corn, that is, the production of new stalks round the original plume, there is every reason to believe that oxygen must be absorbed; for the stalk at which the tillering takes place always contains sugar, and the shoots arise from a part deprived of light. The drill husbandry favors this process; for loose earth is thrown by hoing round the stalks: they are preserved from light, and yet supplied with oxygen. I have counted from 40 to 120 stalks produced from a grain of wheat, in a moderately good crop of drilled wheat. And we are informed by Sir Kenelm Digby, in 1660, that there was in the possession of the Fathers of the Christian Doctrine at Paris, a plant of barley, which they, at that time, kept by them as a curiosity, and which consisted of 249 stalks springing from one root, or grain; and in which they counted above 18,000 grains or seeds of barley.

The great increase which takes place in the transplantation of wheat depends upon the circumstance, that each layer thrown out in tillering may be removed, and treated as a distinct plant. In the Philosophical Transactions, vol. lviii. page 203, the following statement may be found: Mr. C. Miller, of Cambridge, sowed some wheat on the 2d of June, 1766; and on the 8th of August, a plant was taken and separated into 18 parts, and replanted; these plants were again taken up, and divided in the months of September and October, and planted separately to stand the winter, which division produced 67 plants. They were again taken up in March and April, and produced 500 plants: the number of ears thus formed from one grain of wheat was 21,109, which gave three pecks and three quarters of corn that weighed 47 lbs. 7 oz., and that were estimated at 576,840 grains.

It is evident from the statements just given, that the change which takes place in the juices of the leaf by the action of the solar light, must tend to increase the proportion of inflammable matter to their other constituent parts. And the leaves of the plants that grow in darkness or in shady places are uniformly pale; their juices are watery and saccharine, and they do not afford oils or resinous substances. I shall detail an experiment on this subject.

I took an equal weight, 400 grains, of the leaves of two plants of endive; one bright green, which had grown fully exposed to light, and the other almost white, which had been secluded from light by being covered with a box; after being both acted upon for some time by boiling water, in the state of pulp, the undissolved matter was dried, and exposed to the action of warm alcohol. The matter from the green leaves gave it a tinge of olive; that from the pale leaves did not alter its color. Scarcely any solid matter was produced by evaporation of the alcohol that had been digested on the pale leaves: whereas, by the evaporation of that from the green leaves a considerable residuum was obtained; five grains of which were separated from the vessel in which the evaporation was carried on; they burnt with flame, and appeared partly matter analogous to resin: 53 grains of woody fibre were obtained from the green leaves, and only 31 from the pale leaves.

It has been mentioned in the third lecture, that the sap probably, in common cases, descends from the leaves into the bark; the bark is usually so loose in its texture, that the atmosphere may possibly act upon it in the cortical layers; but the changes taking place in the leaves appear sufficient to explain the difference between the products obtained from the bark and from the alburnum; the first of which contains more carbonaceous matter than the last.

When the similarity of the elements of different vegetable products is considered according to the views given in the third lecture, it is easy to conceive how the different organized parts may be formed from the same sap, according to the manner in which it is acted on by heat, light, and air. By the abstraction of oxygen, the different inflammable products, fixed and volatile oils, resins, camphor, woody fibre, &c., may be produced from saccharine or mucilaginous fluids; and by the abstraction of carbon and hydrogen, starch, sugar, the different vegetable acids and substances soluble in water, may be formed with highly combustible and insoluble substances. Even the limpid volatile oils which convey the fragrance of the flower, consist of different proportions of the same essential elements as the dense woody fibre; and both are formed by different changes in the same organs, from the same materials, and at the same time.

M. Vauquelin has lately attempted to estimate the chemical changes taking place in vegetation, by analyzing some of the organized parts of the horse-chestnut in their different stages of growth. He found in the buds collected, March 7, 1812, tanning principle, and albuminous matter capable of being obtained separately, but, when obtained, combining with each other. In the scales surrounding the buds, he found the tanning principle, a little saccharine matter, resin, and a fixed oil. In the leaves fully developed, he discovered the same principles as in the buds; and in addition, a peculiar green resinous matter. The petals of the flower yielded a yellowish resin, saccharine matter, albuminous matter, and a little wax: the stamina afforded sugar, resin, and tannin.

The young chestnuts examined immediately after their formation, afforded a large quantity of a matter which appeared to be a combination of albuminous matter and tannin. All the parts of the plant afforded saline combinations of the acetic and phosphoric acids.

M. Vauquelin could not obtain a sufficient quantity of the sap of the horse-chestnut for examination, a circumstance much to be regretted; and he has not stated the relative quantities of the different substances in the buds, leaves, flowers, and seeds. It is probable, however, from his unfinished details, that the quantity of resinous matter is increased in the leaf, and that the white fibrous pulp of the chestnut is formed by the mutual action of albuminous and astringent matter, which probably are supplied by different cells or vessels. I have already mentioned that the cambium, from which the new parts in the trunk and branches appear to be formed, probably owes its power of consolidation to the mixture of two different kinds of sap, one of which flows upwards from the roots, and the other of which probably descends from the leaves. I attempted, in May, 1804, at the time the cambium was forming in the oak, to ascertain the nature of the action of the sap of the alburnum upon the juices of the bark. By perforating the alburnum in a young oak, and applying an exhausting syringe to the aperture, I easily drew out a small quantity of sap. I could not, however, in the same way obtain sap from the bark. I was obliged to recur to the solution of its principles in water, by infusing a small quantity of fresh bark in warm water; the liquid obtained in this way was highly colored and astringent; and produced an immediate precipitate in the alburnous sap, the taste of which was sweetish, and slightly astringent, and which was colorless.

The increase of trees and plants must depend upon the quantity of sap which passes into their organs; upon the quality of this sap; and on its modification by the principles of the atmosphere. Water, as it is the vehicle of the nourishment of the plant, is the substance principally given off by the leaves. Dr. Hales found that a sunflower, in one day of twelve hours, transpired by its leaves one pound fourteen ounces of water, all of which must have been imbibed by its roots.

The powers which cause the ascent of the sap have been slightly touched upon in the second and third lectures. The roots imbibe fluids from the soil by capillary attraction; but this power alone is insufficient to account for the rapid elevation of the sap into the leaves. This is fully proved by the following fact, detailed by Dr.

Hales, vol. i. of the Vegetable Statics, page 114: A vine branch, four or five years old, was cut through, and a glass tube carefully attached to it; this tube was bent as a syphon, and filled with quicksilver; so that the force of the ascending sap could be measured by its effect in elevating the quicksilver. In a few days it was found that the sap had been propelled forwards with so much force as to raise the quicksilver to 38 inches, which is a force considerably superior to that of the usual pressure of the atmosphere. Capillary attraction can only be exerted by the surfaces of small vessels, and can never raise a fluid into tubes above the vessels themselves.

I referred, in the beginning of the third lecture, to Mr. Knight's opinion, that the contractions and expansions of the silver grain in the alburnum are the most efficient cause of the ascent of the fluids contained in its pores and vessels. The views of this excellent physiologist are rendered extremely probable by the facts he has brought forward in support of them. Mr. Knight found that a very small increase of temperature was sufficient to cause the fibres of the silver grain to separate from each other, and that a very slight diminution of heat produced their contraction. The sap rises most vigorously in spring and autumn, at the time the temperature is variable; and if it be supposed that, in expanding and contracting, the elastic fibres of the silver grain exercise a pressure upon the cells and tubes containing the fluid absorbed by the capillary attraction of the roots, this fluid must constantly move upwards towards the points where a supply is needed.

The experiments of Montgolfier, the celebrated inventor of the balloon, have shown that water may be raised almost to an indefinite height by a very small force, provided its pressure be taken off by continued divisions in the column of fluid. This principle, there is great reason to suppose, must operate in assisting the ascent of the sap in the cells and vessels of plants which have no rectilineal communication, and which every where oppose obstacles to the perpendicular pressure of the sap.

The changes taking place in the leaves and buds, and the degree of their power of transpiration, must be intimately connected likewise with the motion of the sap upwards. This is shown by several experiments of Dr. Hales.

A branch from an apple-tree was separated and introduced into water, and connected with a mercurial gauge. When the leaves were upon it, it raised the mercury by the force of the ascending juices to four inches; but a similar branch, from which the leaves were removed, scarcely raised it a quarter of an inch.

Those trees, likewise, whose leaves are soft and of a spongy texture, and porous at their upper surfaces, displayed by far the greatest powers with regard to the elevation of the sap.

The same accurate philosopher whom I have just quoted found that the pear, quince, cherry, walnut, peach, gooseberry, water-elder, and sycamore, which have all soft and unvarnished leaves, raised the mercury under favorable circumstances from three to six inches. Whereas the elm, oak, chestnut, hazel, sallow, and ash, which have firmer and more glossy leaves, raised the mercury only from one to two inches. And the evergreens, and trees bearing varnished leaves, scarcely at all affected it; particularly the laurel and the laurustinus.

It will be proper to mention the facts which show that in many cases fluids descend through the bark. Mr. Knight has shown, in the Philosophical Transactions, that long strips of bark, every where detached from the alburnum of the tree, except at their upper ends, deposited as much alburnum as they could have done, if they had retained their natural position. In these cases, the sap must have descended through the bark wholly.

M. Baisse placed branches of different trees in an infusion of madder, and kept them there for a long time. He found, in all cases, that the wood became red before the bark; and that the bark began to receive no tinge till the whole of the wood was colored, and till the leaves were affected; and that the coloring matter first appeared above, in the bark immediately in contact with the leaves.

Similar experiments were made by M. Bonnet, and with analogous results, though not so perfectly distinct as those of M. Baisse.

Du Hamel found, that in different species of the pine and other trees, when strips of bark were removed, the upper part of the wound only emitted fluid, whilst the lower part remained dry.

This may likewise be observed in the summer in fruit trees, when the bark is wounded, the alburnum remaining untouched.

The motion of the sap through the bark seems principally to depend upon gravitation. When the watery particles have been considerably dissipated by the transpiring functions of the leaves, and the mucilaginous, inflammable, and astringent constituents, increased by the agency of heat, light, and air, the continued impulse upwards from the alburnum forces the remaining inspissated fluid into the cortical vessels, which receive no other supply. In these, from its weight, its natural tendency must be to descend; and the rapidity of the descent must depend upon the general consumption of the fluids of the bark in the living processes of vegetation; for there is every reason to believe that no fluid passes into the soil through the roots; and it is impossible to conceive a free lateral communication between the absorbent vessels of the alburnum in the roots, and the transporting or carrying vessels of the bark; for if such a communication existed, there is no reason why the sap should not rise through the bark as well as through the alburnum; for the same physical powers would then operate upon both.

Some authors have supposed that the sap rises in the alburnum, and descends through the bark, in consequence of a power similar to that which produces the circulation of the blood in animals; a force analogous to the muscular force in the sides of the vessels.

This analogy has, however, in general, been too much insisted upon and too loosely stated; there are undoubtedly resemblances more or less remote in every part of created nature; but the irritability of the muscular fibre in animals and the contractibility of the vascular system in plants appear to depend upon entirely different causes.

In crystallization, or the regular arrangement of inorganic substances, there is a constant increase of matter from the attraction and juxta-position of like parts or molecules. In vegetation a germ expands by the assimilation of a variety of new aliments, and by powers entirely different from those of common inorganic matter; but there seems to be no system of nerves, as in animals, which is essential to irritability. We know so little of the refined powers and properties of matter, that we can give little more than vague hypotheses as to the cause of the movement of the fluids in the vegetable cells or tubes; yet it is impossible not to allow common material agents a much greater share in producing this phenomenon, than they exercise in animal life.

Whoever will peruse any considerable part of the Vegetable Statics of Hales, must receive a deep impression of the dependence of the motion of the sap upon physical causes. In the same tree, this sagacious person observed that in a cold cloudy morning, when no sap ascended, a sudden change was produced by a gleam of sunshine of half an hour, and a vigorous motion of the fluid. The alteration of the wind from south to the north immediately checked the effect. On the coming on of a cold afternoon after a hot day, the sap that had been rising began to fall. A warm shower and a sleet storm produced opposite effects.

Many of his observations likewise show that the different powers which act on the adult tree, produce different effects at different seasons.

Thus, in the early spring, before the buds expand, the variations of the temperature, and changes of the state of the atmosphere with regard to moisture and dryness, exert their great effects upon the expansions and contractions of the vessels; and then the tree is in what is called by gardeners its bleeding season.

When the leaves are fully expanded, the great determination of the sap is to these new organs. And hence a tree which emits sap copiously from a wound whilst the buds are opening, will no longer emit it in summer when the leaves are perfect; but in the variable weather, towards the end of autumn, when the leaves are falling, it will again possess the power of bleeding in a very slight degree in the warmest days: but at no other times.

In all these circumstances there is nothing truly analogous to the irritable action of animal systems.

In animal systems the heart and arteries are in constant pulsation. Their functions are unceasingly performed in all climates, and in all seasons; in winter, as well as in spring; upon the arctic snows, and under the tropical suns. They neither cease in the periodical nocturnal sleep, common to most animals; nor in the long sleep of winter, peculiar to a few species. The power is connected with animation, is limited to beings possessing the means of voluntary locomotion; it co-exists with the first appearance of vitality; it disappears only with the last spark of life.

As the operation of the different physical agents upon the sap vessels of plants ceases, and the fluid becomes quiescent, the materials dissolved in it by heat are deposited in the cells of the alburnum; and in consequence of this deposition, a nutritive matter is provided for the first wants of the plant in early spring, to assist the opening of the buds, and their expansion, when the motion from the want of leaves is as yet feeble.

This beautiful principle in the vegetable economy was first pointed out by Dr. Darwin; and Mr. Knight has given a number of experimental elucidations of it.

Mr. Knight made numerous incisions into the alburnum of the sycamore and the birch at different heights; and in examining the sap that flowed from them, he found it more sweet and mucilaginous in proportion as the aperture from which it flowed was elevated; which he could ascribe to no other cause than to its having dissolved sugar and mucilage, which had been stored up through the winter.

He examined the alburnum in different poles of oak in the same forest; of which some had been felled in winter, and others in summer; and he always found most soluble matter in the wood felled in winter, and its specific gravity was likewise greater.

In all perennial trees this circumstance takes place; and likewise in grasses and shrubs. The joints of the perennial grasses contain more saccharine and mucilaginous matter in winter than at any other season; and this is the reason why the fiorin or agrostis alba, which abounds in these joints, affords so useful a winter food.

The roots of shrubs contain the largest quantity of nourishing matter in the depth of winter; and the bulb in all plants possessing it is the receptacle in which nourishment is hoarded up during winter.

In annual plants the sap seems to be fully exhausted of all its nutritive matter by the production of flowers and seeds; but if parts of annual plants, having leaves and buds, be detached and kept so that they do not expend themselves by affording blossoms or seeds, the same individual life may be preserved through many years. It appears, therefore, as Mr. Knight observes, to be habit only, not life, that is annual in such plants.

When perennial grasses are cropped very close by feeding cattle late in autumn, it has been often observed by farmers that they never rise vigorously in the spring; and this is owing to the removal of that part of the stalk which would have afforded them concrete sap, their first nourishment.

Ship-builders prefer for their purposes that kind of oak timber afforded by trees that have had their bark stripped off in spring, and which have been cut in the autumn or winter following. The reason of the superiority of this timber is, that the concrete sap is expended in the spring in the sprouting of the leaf; and the circulation being destroyed, it is not formed anew; and the wood having its pores free from saccharine matter, is less liable to undergo fermentation from the action of moisture and air.

In perennial trees a new alburnum, and consequently a new system of vessels is annually produced, and the nutriment for the next year deposited in them; so that the new buds, like the plume of the seed, are supplied with a reservoir of matter essential to their first developement.

The old alburnum gradually loses its vascular structure, and, being constantly pressed upon by the expansive force of the new fibres, becomes harder, denser, and at length becomes heart-wood; and in a certain time obeys the common laws of dead matter, decays, decomposes, and it is converted into aëriform and carbonic elements; into those principles from which it was originally formed.

The decay of the heart-wood seems to constitute the great limit to the age and size of trees.—And in young branches from old trees, it is much more liable to decompose than in similar branches from seedlings. This is likewise the case with grafts. The graft is only nourished by the sap of the tree to which it is transferred; its properties are not changed by it: the leaves, blossoms, and fruits are of the same kind as if it had vegetated upon its parent stock. The only advantage to be gained in this way, is the affording to a graft from an old tree a more plentiful and healthy food than it could have procured in its natural state; it is rendered for a time more vigorous, and produces fairer blossoms and richer fruits. But it partakes not merely of the obvious properties, but likewise of the infirmities and disposition to old age and decay of the tree whence it sprung.

This seems to be distinctly shown by the observations and experiments of Mr. Knight. He has, in a number of instances, transferred the young scions and healthy shoots from old esteemed fruit-bearing trees to young seedlings. They flourished for two or three years; but they soon became diseased and sickly, like their parent trees.

It is from this cause that so many of the apples formerly celebrated for their taste and their uses in the manufacture of cider are gradually deteriorating, and many will soon disappear. The red streak, and the moil, so excellent in the beginning of the last century, are now in the extremest stage of their decay; and however carefully they are ingrafted, they merely tend to multiply a sickly and exhausted variety.*

The tress possessing the firmest and the least porous heart-wood are the longest in duration.

In general, the quantity of charcoal afforded by woods offers a tolerably accurate indication of their durability: those most abundant in charcoal and earthy matter are most permanent; and those that contain the largest proportion of gaseous elements are the most destructible.

Amongst our own trees, the chestnut and the oak are pre-eminent as to durability; and the chestnut affords rather more carbonaceous matter than the oak.

In old Gothic buildings these woods have been sometimes mistaken one for the other; but they may be easily known by this circumstance, that the pores in the alburnum of the oak are much larger and more thickly set, and are easily distinguished; whilst the pores in the chestnut require glasses to be seen distinctly.

In consequence of the slow decay of the heart-wood of the oak and chestnut, these trees, under favorable circumstances, attain an age which cannot be much short of 1000 years.

The beech, the ash, and the sycamore, most likely never live half as long. The duration of the apple-tree is not, probably, much more than 200 years; but the pear-tree, according to Mr. Knight, lives through double this period. Most of our best apples are supposed to have been introduced into Britain by a fruiterer of Henry the Eighth, and they are now in a state of old age.

The oak and chestnut decay much sooner in a moist situation than in a dry and sandy soil; and their timber is less firm. The sap vessels in such cases are more expanded, though less nourishing matter is carried into them; and the general texture of the formations of wood necessarily less firm. Such wood splits more easily, and is more liable to be affected by variations in the state of the atmosphere.

The same trees, in general, are much longer-lived in the northern than in the southern climates. The reason seems to be, that all fermentation and decomposition are checked by cold; and at very low temperatures both animal and vegetable matters altogether resist putrefaction: and in the northern winter, not only vegetable life, but likewise vegetable decay, must be at a stand.

The anti-putrescent quality of cold climates is fully illustrated in the instances of the rhinoceros and mammoth, lately found in Siberia, entire beneath the frozen soil, in which they must probably have existed from the time of the deluge. I examined a part of the skin of the mammoth sent to this country, on which there was some coarse hair; it had all the chemical characters of recently dried skin.

Trees that grow in situations much exposed to winds, have harder and firmer wood than such as are considerably sheltered. The dense sap is determined by the agitation of the smaller branches to the trunk and larger branches, where the new alburnum formed is consequently thick and firm. Such trees abound in the crooked limbs fitted for forming knee-timber, which is necessary for joining the decks and the sides of ships. The gales in elevated situations gradually act so as to give the tree the form best calculated to resist their effects. And the mountain oak rises robust and sturdy; fixed firmly in the soil, and able to oppose the full force of the tempest.

The decay of the best varieties of fruit-bearing trees which have been distributed through the country by grafts, is a circumstance of great importance. There is no mode of preserving them; and no resource, except that of raising new varieties by seeds.

Where a species has been ameliorated by culture, the seeds it affords, other circumstances being similar, produce more vigorous and perfect plants; and in this way the great improvements in the production of our fields and gardens seem to have been occasioned.

Wheat, in its indigenous state, as a natural production of the soil, appears to have been a very small grass; and the case is still more remarkable with the apple and the plum. The crab seems to have been the parent of all our apples. And two fruits can scarcely be conceived more different, in color, size, and appearance, than the wild plum and the rich magnum bonum.

The seeds of plants exalted by cultivation always furnish large and improved varieties; but the flavor, and even the color of the fruit, seems to be a matter of accident. Thus a hundred seeds

* This opinion relative to the loss of varieties of fruit-bearing trees is not in accordance with the views of M. De Candolle on the subject of the length of life of trees; viz. that, excluding accidents and disease, it is unlimited. Much deference is due to so high an authority; and, assuredly, the doctrine of Mr. Knight, referred to above, should not be received and acted on by practical men, unless clearly demonstrated to be true, because, if taken for granted, it will necessarily lead to the neglect of old varieties of fruit-trees, on the idea that they are in the decline and decrepitude of age, and about to die. *Vide* Physiologie Végétale, liv. 4, chap. xi., where the subject is most ingeniously discussed.—J. D.

of the golden pippin will 'all produce fine large-leaved apple trees, bearing fruit of a considerable size; but the tastes and colors of the apples from each will be different, and none will be the same in kind as those of the pippin itself. Some will be sweet, some sour, some bitter, some mawkish, some aromatic; some yellow, some green, some red, and some streaked. All the apples will, however, be much more perfect than those from the seeds of a crab, which produce trees all of the same kind, and all bearing sour and diminutive fruit.

The power of the horticulturist extends only to the multiplying excellent varieties by grafting. They cannot be rendered permanent; and the good fruits at present in our gardens are the produce of a few seedlings, selected probably from hundreds of thousands; the results of great labor and industry, and multiplied experiments.

The larger and thicker the leaves of a seedling, and the more expanded its blossoms, the more it is likely to produce a good variety of fruit. Short-leaved trees should never be selected; for these approach nearer to the original standard: whereas the other qualities indicate the influence of cultivation.

In the general selection of seeds, it would appear that those arising from the most highly cultivated varieties of plants, are such as give the most vigorous produce; but it is necessary from time to time to change, and, as it were, to cross the breed.

By applying the pollen, or dust of the stamina, from one variety to the pistil of another of the same species, a new variety may be easily produced; and Mr. Knight's experiments seem to warrant the idea that great advantages may be derived from this method of propagation.

Mr. Knight's large peas, produced by crossing two varieties, are celebrated amongst horticulturists, and will, I hope, soon be cultivated by farmers.

I have seen several of his crossed apples, which promise to rival the best of those which are gradually dying away in the cider countries.

And his experiments on the crossing of wheat, which is very easily effected, merely by sowing the different kinds together, lead to a result which is of considerable importance. He says, in the Philosophical Transactions for 1799, "In the years 1795 and 1796, when almost the whole crop of corn in the island was blighted, the varieties obtained by crossing *alone* escaped, though sown in several soils, and in very different situations."

The processes of gardening for increasing the number of fruit-bearing branches, and for improving the fruit upon particular branches, will all admit of elucidation from the principles that have been advanced in this lecture.

By making trees espaliers, the force of gravity is particularly directed towards the lateral parts of the branches, and more sap determined towards the fruit buds: and hence they are more likely to bear when in a horizontal than when in a vertical position.

The twisting of a wire, or tying a thread round a branch, has been often recommended as a means of making it produce fruit. In this case the descent of the sap in the bark must be impeded above the ligature; and more nutritive matter consequently retained and applied to the expanding parts.

In engrafting, the vessels of the bark of the stock and the graft cannot so perfectly come in contact as the alburnous vessels, which are much more numerous, and equally distributed; hence the circulation downwards is probably impeded, and the tendency of the graft to evolve its fruit-bearing buds increased.

In transplanting trees, if their size is at all considerable, they should be stripped of a portion of their branches and leaves by cutting; for they must in the process of removal from the soil lose a great part of their roots and fine radical fibres; and supposing all their leaves remaining, they would die from exhaustion of their moisture by the great evaporating surface.

By lopping trees more nourishment is supplied to the remaining parts; for the sap flows laterally as well as perpendicularly. The same reasons will apply to explain the increase of the size of fruits by diminishing the number upon a tree.

As plants are capable of amelioration by peculiar methods of cultivation, and of having the natural term of their duration extended; so, in conformity to the general law of change, they are rendered unhealthy by being exposed to peculiarly unfavorable circumstances, and liable to permature old age and decay.

The plants of warm climates transported into cold ones, or of cold ones transported into warm ones, if not absolutely destroyed by the change of situation, are uniformly rendered unhealthy.

Few of the tropical plants, as is well known, can be raised in this country, except in hot houses. The vine during the whole of our summer may be said to be in a feeble state with regard to health; and its fruit, except in very extraordinary cases, always contains a superabundance of acid. The gigantic pine of the north, when transported into the equatorial climates, becomes a degenerated dwarf; and a great number of instances of the same kind might be brought forward.

Much has been written, and many very ingenious remarks have been made by different philosophers, upon what have been called the habits of plants. Thus in transplanting a tree, it dies or becomes unhealthy, unless its position with respect to the sun is the same as before. The seeds brought from warm climates germinate here much more early in the season than the same species brought from cold climates. The apple-tree from Siberia, where the short summer of three months immediately succeeds the long winter, in England, usually puts forth is blossoms in the first year of its transplantation, on the appearance of mild weather; and is often destroyed by the late frosts of the spring.

It is not difficult to explain this principle so intimately connected with the healthy or diseased state of plants. The organization of the germ, whether in seeds or buds, must be different, according as more or less heat or alternations of heat and cold have affected it during its formation; and the nature of its expansion must depend wholly on this organization. In a changeable climate the formations will have been interrupted, and in different successive layers. In an equal temperature they will have been uniform; and the operation of new and sudden causes will of course be severely felt.

The disposition of trees may, however, be changed gradually in many instances; and the operation of a new climate in this way be made supportable. The myrtle, a native of the south of Europe, inevitably dies if exposed in the early state of its growth to the frosts of our winter; but if kept in a green-house during the cold season for successive years, and gradually exposed to low temperatures, it will, in an advanced stage of growth, resist even a very severe cold. And in the south and west of England the myrtle flourishes, produces blossoms and seeds, in consequence of this process, as an unprotected standard tree; and the layers from such trees are much more hardy than the layers from myrtles reared within doors.

The arbutus, probably originally from similar cultivation, has become the principal ornament of the lakes of the south of Ireland. It thrives even in bleak mountain situations; and there can be little doubt but that the offspring of this tree, inured to a temperate climate, might be easily spread in Britain.

The same principles that apply to the effects of heat and cold will likewise apply to the influence of moisture and dryness. The layers of a tree habituated to a moist soil will die in a dry one; even though such a soil is more favorable to the general growth of the species. And, as was already stated, trees that have been raised in the centre of woods are sooner or later destroyed, if exposed in their adult state to blasts, in consequence of the felling of the surrounding timber.

Trees, in all cases in which they are exposed in high and open situations to the sun, the winds, and the rain, as I just now noticed, become low and robust, exhibiting curved limbs, but never straight and graceful trunks. Shrubs and trees, on the contrary, which are too much sheltered, too much secluded from the sun and wind, extend exceedingly in height, but present at the same time slender and feeble branches; their leaves are pale and sickly, and in extreme cases they do not bear fruit. The exclusion of light alone is sufficient to produce this species of disease, as would appear from the experiments of Bonnet. This ingenious physiologist sowed three seeds of the pea in the same kind of soil: one he suffered to remain exposed to the free air; the other he inclosed in a tube of glass; and the third in a tube of wood. The pea in the tube of glass sprouted, and grew in a manner scarcely at all different from that under usual circumstances; but the plant in the tube of wood, deprived of light, became white and slender, and grew to a much greater height.

The plants growing in a soil incapable of supplying them with sufficient manure, or dead organized matter, are very generally low, having brown or dark green leaves; and their woody fibre abounds in earth.* Those vegetating in peaty soils, or in lands too copiously supplied with animal or vegetable matter, rapidly expand, produce large bright green leaves, abound in sap, and generally blossom prematurely.

Where a land is too rich for corn, it is not an uncommon practice to cut down the first stalks, as by these means its exuberance is corrected, and it is less likely to fall before the grain is ripe; excess of poverty, or of richness, is almost equally fatal to the hopes of the farmer; and the true constitution of the soil for the best crop is that in which the earthy materials, the moisture and manure, are properly associated; and in which the decomposable vegetable or animal matter does not exceed one-fourth of the weight of the earthy constituents.

The canker, or erosion of the bark and wood, is a disease produced often in trees by a poverty of soil; and it is invariably connected with old age. The cause seems to be an excess of alkaline and earthy matter in the descending sap. I have often found carbonate of lime on the edges of the canker in apple trees; and ulmin, which contains fixed alkali, is abundant in the canker of the elm. The old age of a tree, in this respect, is faintly analogous to the old age of animals, in which the secretions of solid bony matter are always in excess, and the tendency to ossification great.

The common modes of attempting to cure the canker are by cutting the edges of the bark, binding new bark upon it, or laying on a plaster of earth; but these methods, though they have been much extolled, probably do very little in producing a regeneration of the part. Perhaps the application of a weak acid to the canker might be of use; or where the tree is of great value, it may be watered occasionally with a very diluted acid. The alkaline and earthy nature of the morbid secretion warrants the trial; but circumstances that cannot be foreseen may occur to interfere with the success of the experiment.

Besides the diseases having their source in the constitution of the plant, or in the unfavorable operation of external elements, there are many others perhaps more injurious, depending upon the operations and powers of other living beings; and such are the most difficult to cure, and the most destructive to the labors of the husbandman.

Parasitical plants of different species, which attach themselves to trees and shrubs, feed on their juices, destroy their health, and finally their life, abound in all climates; and are, perhaps, the most formidable of the enemies of the superior and cultivated vegetable species.

The mildew, which has often occasioned great havoc in our wheat crops, and which was particularly destructive in 1804, is a species of fungus, so small as to require glasses to render its form distinct, and rapidly propagated by its seeds.

This has been shown by various botanists; and the subject has received a full illustration from the researches of the late ever to be lamented Sir Joseph Banks.

The fungus rapidly spreads from stalk to stalk, fixes itself in the cells connected with the common tubes, and carries away and consumes that nourishment which should have been appropriated to the grain.

Various remedies have been proposed for this disease. The Rev. Dr. Cartwright states that he

* This is very strikingly illustrated in many of the plants which grow out of the soft free-stone rock of Malta: their growth is stunted; their roots large, branches and leaves small; and their leaves as well as branches abound in lime. From what I have witnessed in that island, I am disposed to believe that plants are instrumental in effecting cavities in calcareous rocks, and that many perforations which have been referred to the operation of boring salt-water mollusca are owing to vegetable growth and decay.—J. D.

has successfully treated it, by the application of a solution of salt, by a common gardening pot, to the stalks of the corn. This is a subject worthy of the most minute investigation; and all methods should be tried which promise to eradicate so great an evil. As the fungus increases by the diffusion of its seeds, great care should be taken that no mildewed straw is carried in the manure used for corn; and in the early crop, if mildew is observed upon any of the stalks of corn, they should be carefully removed, and treated as weeds.

The popular notion amongst farmers, that a barberry-tree in the neighborhood of a field of wheat often produces the mildew, deserves examination. This tree is frequently covered with a fungus, which, if it should be shown to be capable of degenerating into the wheat fungus, would offer an easy explanation of the effect.

There is some reason to believe, from the researches of Sir Joseph Banks, that the smut in wheat likewise is produced by a very small fungus which fixes on the grain; the products that it affords by analysis are similar to those afforded by the puff-ball; and it is difficult to conceive, that without the agency of some organized structure, so complete a change should be effected in the constitution of the grain.

The misletoe and the ivy, the moss and the lichen, in fixing upon trees, uniformly injure their vegetative processes, though in very different degrees. They are supported from the lateral sap-vessels, and deprive the branches above of a part of their nourishment.

The insect tribes are scarcely less injurious than the parasitical plants.

To enumerate all the animal destroyers and tyrants of the vegetable kingdom, would be to give a catalogue of the greater number of the classes in zoology. Every species of plant almost is the peculiar resting-place or dominion of some insect tribe; and from the locust, the caterpillar, and snail, to the minute aphis, a wonderful variety of the inferior insects are nourished, and live by their ravages upon the vegetable world.

I have already referred to the insect which feeds on the seed-leaf of the turnip.

The Hessian fly, still more destructive to wheat, has, in some seasons, threatened the United States with a famine. And the French government, in 1813, issued decrees with a view to occasion the destruction of the larvæ of the grasshopper.

In general, wet weather is most favorable to the propagation of mildew, funguses, rust, and the small parasitical vegetables; dry weather to the increase of the insect tribes. Nature, amidst all her changes, is continually directing her resources towards the production and multiplication of life; and in the wise and grand economy of the whole system, even the agents that appear injurious to the hopes, and destructive to the comforts of man, are, in fact, ultimately connected with a more exalted state of his powers and his condition. His industry is awakened, his activity kept alive, even by the defects of climates and season. By the accidents which interfere with his efforts, he is made to exert his talents, to look farther into futurity, and to consider the vegetable kingdom not as a secure and unalterable inheritance, spontaneously providing for his wants; but as a doubtful and insecure possession, to be preserved only by labor, and extended and perfected by ingenuity.

LECTURE VI.

ON MANURES OF VEGETABLE AND ANIMAL ORIGIN. OF THE MANNER IN WHICH THEY BECOME THE NOURISHMENT OF THE PLANT. OF FERMENTATION AND PUTREFACTION. OF THE DIFFERENT SPECIES OF MANURES OF VEGETABLE ORIGIN; OF THE DIFFERENT SPECIES OF ANIMAL ORIGIN. OF MIXED MANURES. GENERAL PRINCIPLES WITH RESPECT TO THE USE AND APPLICATION OF SUCH MANURES.

That certain vegetable and animal substances introduced into the soil accelerate vegetation and increase the product of crops, is a fact known since the earliest period of agriculture; but the manner in which manures act, the best modes of applying them, their relative value and durability, are still subjects of discussion. In this lecture, I shall endeavor to lay down some settled principles on these objects; they are capable of being materially elucidated by the recent discoveries in chemistry; and I need not dwell on their great importance to farmers.

The pores in the fibres of the roots of plants are so small, that it is with difficulty they can be discovered by the microscope; it is not, therefore, probable that solid substances can pass into them from the soil. I tried an experiment on this subject: some impalpable powdered charcoal, procured by washing gunpowder, and dissipating the sulphur by heat, was placed in a phial containing pure water in which a plant of peppermint was growing; the roots of the plant were pretty generally in contact with the charcoal. The experiment was made in the beginning of May, 1805; the growth of the plant was very vigorous during a fortnight, when it was taken out of the phial: the roots were cut through in different parts; but no carbonaceous matter could be discovered in them, nor were the smallest fibrils blackened by charcoal, though this must have been the case had the charcoal been absorbed in a solid form.

No substance is more necessary to plants than carbonaceous matter; and if this cannot be introduced into the organs of plants except in a state of solution, there is every reason to suppose that other substances less essential will be in the same case.

I found by some experiments made in 1804, that plants introduced into strong fresh solutions of sugar, mucilage, tanning principle, jelly, and other substances, died: but that plants lived in the same solutions after they had fermented. At that time, I supposed that fermentation was necessary to prepare the food of plants; but I have since found that the deleterious effect of the recent vegetable solutions was owing to their being too concentrated; in consequence of which the vegetable organs were probably clogged with solid matter, and the transpiration by the leaves prevented. In the beginning of June, in the next year, I used solutions of the same substances; but so much diluted, that there was only about one-two hundredth part of solid vegetable or animal matter in the solutions. Plants of mint grow luxuriantly in all these solutions; but least so in that of the astringent matter. I watered some spots of grass in a garden with the different solutions separately, and a spot with common water: the grass watered with solutions of jelly, sugar, and mucilage, grew most vigorously; and that watered with the solution of the tanning principle grew better than that watered with common water.

I endeavored to ascertain whether soluble vegetable substances passed in an unchanged state into the roots of plants, by comparing the products of the analysis of the roots of some plants of mint which had grown, some in common water, some in a solution of sugar: 120 grains of the roots of the mint which grew in the solution of sugar afforded five grains of pale green extract, which had a sweetish taste, but which slightly coagulated by the action of alcohol: 120 grains of the roots of the mint which had grown in common water yielded three grains and a half of extract, which was of a deep olive color; its taste was sweetish, but more astringent than that of the other extract, and it coagulated more copiously with alcohol.

These results, though not quite decisive, favor the opinion that soluble matters pass unaltered into the roots of plants; and the idea is confirmed by the circumstances that the radical fibres of plants made to grow in infusions of madder are tinged red; and it may be considered as almost proved by the fact, that substances which are even poisonous to vegetables are absorbed by them. I introduced the roots of a primrose into a weak solution of oxide of iron in vinegar, and suffered it to remain in it till the leaves became yellow; the roots were then carefully washed in distilled water, bruised, and boiled in a small quantity of the same fluid: the decoction of them passed through a filter was examined by the test of infusion of nutgalls; the decoction gained a strong tint of purple, which proves that solution of iron had been taken up by the vessels or pores in the roots.

Vegetable and animal substances deposited in the soil, as is shown by universal experience, are consumed during the process of vegetation; and they can only nourish the plant by affording solid matters capable of being dissolved by water, or gaseous substances capable of being absorbed by the fluids in the leaves of vegetables; but such parts of them as are rendered gaseous, and that pass into the atmosphere, must produce a comparatively small effect; for gases soon become diffused through the mass of the surrounding air. The great object in the application of manure should be to make it afford as much soluble matter as possible to the roots of the plant: and that in a slow and gradual manner, so that it may be entirely consumed in forming its sap and organized parts.

Mucilaginous, gelatinous, saccharine, oily and extractive fluids, and solution of carbonic acid and water are substances that in their unchanged states contain almost all the principles necessary for the life of plants; but there are few cases in which they can be applied as manures, in their pure forms; and vegetable manures, in general, contain a great excess of fibrous and insoluble matter, which must undergo chemical changes before they can become the food of plants.

It will be proper to take a scientific view of the nature of these changes; of the causes which occasion them, and which accelerate or retard them; and of the products they afford.

If any fresh vegetable matter which contains sugar, mucilage, starch, or other of the vegetable compounds soluble in water, be moistened and exposed to air, at a temperature from 55° to 80°, oxygen will soon be absorbed, and carbonic acid formed; heat will be produced, and elastic fluids, principally carbonic acid, gaseous oxide of carbon, and hydro-carbonate will be evolved; a dark-colored liquid, of a slightly sour or bitter taste, will likewise be formed; and if the process be suffered to continue for a time sufficiently long, nothing solid will remain, except earthy and saline matter, colored black by charcoal.

The dark-colored fluid formed in the fermentation always contains acetic acid; and when albumen or gluten exists in the vegetable substance, it likewise contains volatile alkali.

In proportion as there is more gluten, albumen, or matters soluble in water, in the vegetable substances exposed to fermentation, so in proportion, all other circumstances being equal, will the process be more rapid. Pure woody fibre alone undergoes a change very slowly; but its texture is broken down, and it is easily resolved into new elements when mixed with substances more liable to change, containing more oxygen and hydrogen. Volatile and fixed oils, resins and wax, are more susceptible of change than woody fibre when exposed to air and water, but much less liable than the other vegetable compounds; and even the most inflammable substances, by the absorption of oxygen, become gradually soluble in water.

Animal matters in general are more liable to decompose than vegetable substances; oxygen is absorbed, and carbonic acid and ammonia formed in the process of their putrefaction. They produce fœtid compound elastic fluids, and likewise azote: they afford dark-colored acid, and oily fluids and leave a residuum of salts and earths mixed with carbonaceous matter.

The principal substances which constitute the different parts of animals, or which are found in their blood, their secretions, or their excrements, are gelatine, fibrine, mucus, fatty or oily matter, albumen, urea, uric acid, and different acid, saline, and earthy matters.

Of these *gelatine* is the substance which when combined with water forms jelly. It in very liable to putrefaction. According to MM. Gay Lussac and Thenard, it is composed of

47·88 of carbon.
27·207—oxygen.
7·914—hydrogen.
16·998—azote.

These proportions cannot be considered as definite, for they do not bear to each other the ratios of any simple multiples of the number representing the elements; the case seems to be the same with other animal compounds: and even in vegetable substances in general, as appears from the statements given in the third lecture, the proportions are far from having the same simple relations as in the binary compounds capable of being made artificially; such as acids, alkalies, oxides, and in salts.

Fibrine constitutes the basis of the muscular fibre of animals, and a similar substance may be obtained from recent fluid blood; by stirring it with a stick the fibrine will adhere to the stick. It is not soluble in water; but by the action of acids, as Mr. Hatchett has shown, it becomes soluble, and analogous to gelatine. It is less disposed to putrefy than gelatine.* According to MM. Gay Lussac and Thenard, 100 parts of fibrine contain

Of carbon	- -	53·360
— oxygen	- -	19·685
— hydrogen	- -	7 021
— azote	- -	19·934

Mucus is very analogous to vegetable *gum* in its characters; and as Dr. Bostock has stated, it may be obtained by evaporating saliva. No experiments have been made upon its analysis; but it is probably similar to gum in composition. It is capable of undergoing putrefaction, but less rapidly than fibrine.

Animal fat and *oils* have not been accurately analyzed; but there is great reason to suppose that their composition is analogous to that of similar substances from the vegetable kingdom.

Albumen has been already referred to, and its analysis stated in the third lecture.

Urea may be obtained by the evaporation of human urine till it is of the consistence of a syrup, and the action of alcohol on the crystalline substance which forms when the evaporated matter cools. In this way a solution of urea in alcohol is procured, and the alcohol may be separated from the urea by heat.† Urea is very soluble in water, and is precipitated from water by diluted nitric acid in the form of bright pearl-colored crystals; this property distinguishes it from all other animal substances.

According to Fourcroy and Vauquelin, 100 parts of urea, when distilled, yield

92·027 parts of carbonate of ammonia.
4·608 carburetted hydrogen gas.
3·225 of charcoal.‡

Urea, particularly when mixed with albumen or gelatine, readily undergoes putrefaction.

Uric acid, as has been shown by Dr. Egan, may be obtained from human urine by pouring an acid into it; and it often falls down from urine in the form of brick-colored crystals. It consists of carbon, hydrogen, oxygen, and azote; but their proportions have not yet been determined. Uric acid is one of the animal substances least liable to undergo the process of putrefaction.§

According to the different proportions of these principles in animal compounds, so are the changes they undergo different. When there is much saline or earthy matter mixed or combined with them, the progress of their decomposition is less rapid than when they are principally composed of fibrine, albumen, gelatine, or urea.

The ammonia given off from animal compounds in putrefaction may be conceived to be formed at the time of their decomposition by the combination of hydrogen and azote; except this matter, the other products of putrefaction are analogous to those afforded by the fermentation of vegetable substances; and the soluble substances formed abound in the elements, which are the constituent parts of vegetables, in carbon, hydrogen, and oxygen.

Whenever manures consist principally of matter soluble in water, it is evident that their fermentation or putrefaction should be prevented as much as possible; and the only cases in which these processes can be useful are when the manure consists principally of vegetable or animal fibre. The circumstances necessary for the putrefaction of animal substances are similar to those required for the fermentation of vegetable substances: a temperature above the freezing point; the presence of water, and the presence of oxygen, at least in the first stage of the process.

To prevent manures from decomposing, they should be preserved dry, defended from the contact of air, and kept as cool as possible.

Salt and alcohol appear to owe their powers of preserving animal and vegetable substances to their attraction for water, by which they prevent its decomposing action, and likewise to their excluding air. The use of ice in preserving animal substances is owing to its keeping their temperature low. The efficacy of M. Appert's method of preserving animal and vegetable substances, an account of which has been lately published, entirely depends upon the exclusion of air. This method is by filling a vessel of tin plate or glass with the meat or vegetables; soldering or cementing the top so as to render the vessel air tight; and then keeping it half immersed in a vessel of boiling water for a sufficient time to render the meat or vegetables proper for food. In this last process it is probable that the small quantity of oxygen remaining in the vessel is absorbed; for on opening a tinned iron cannister which had been filled with raw beef, and exposed to hot water the day before, I found that the minute quantity of elastic fluid which could be procured from it, was a mixture of carbonic acid gas and azote.

Where meat or vegetable food is to be preserved on a large scale, for the use of the navy or army, for instance, I am inclined to believe, that by forcibly throwing a quantity of carbonic acid, hydrogen, or azote, into the vessel, by means of a compressing pump, similar to that used for making artificial Seltzer water, any change in the substance would be more effectually prevented. No elastic fluid in this case would have room to form by the decomposition of the meat; and the tightness and strength of the vessel would be proved by the process. No putrefaction or fermentation can go on without the generation of elastic fluid; and pressure would probably act with as much efficacy as cold in the preservation of animal or vegetable food.

* Fibrine, especially of the blood, according to my experience, putrefies more readily than any other animal substance. In a few hours, at the temperature of 80° Fahrenheit, exposed to the air, by putrefacion it is reduced from a solid to a liquid: the change is accompanied by a considerable disengagement of heat, and formation of ammonia and carbonic acid.—J. D.

† It is best obtained from the nitrate of urea, by means of carbonate of potash and alcohol, according to Dr. Prout's method. Pure urea is colorless, crystallizes in four-sided prisms, and its solution in water resists change for many weeks or even months. It is the only animal compound (or proximate principle) which hitherto has been formed artificially.—J. D.

‡ According to the analysis of Dr. Prout, it consists of

Carbon	- - -	12·24
Nitrogen	- - -	22·3
Hydrogen	- - -	4
Oxygen	- - -	16—J. D.

§ It has lately been analysed by Liebig, and found to consist of

Carbon	- - -	36·11
Hydrogen	- - -	2 34
Nitrogen	- - -	33·36
Oxygen	- - -	28·10

When pure, it is colorless, tasteless, and without odor.—J. D.

As different manures contain different proportions of the elements necessary to vegetation, so they require a different treatment to enable them to produce their full effects in agriculture. I shall therefore describe in detail the properties and nature of the manures in common use, and give some general views respecting the best modes of preserving and applying them.

All *green succulent plants* contain saccharine or mucilaginous matter, with woody fibre, and readily ferment. They cannot, therefore, if intended for manure, be used too soon after their death.

When *green crops* are to be employed for enriching a soil, they should be ploughed in, if it be possible, when in flower, or at the time the flower is beginning to appear; for it is at this period that they contain the largest quantity of easily soluble matter, and that their leaves are most active in forming nutritive matter. Green crops, pond weeds, the paring of hedges or ditches, or any kind of fresh vegetable matter, require no preparation to fit them for manure. The decomposition slowly proceeds beneath the soil; the soluble matters are gradually dissolved, and the slight fermentation that goes on, checked by the want of a free communication of air, tends to render the woody fibre soluble without occasioning the rapid dissipation of elastic matter.

When old pastures are broken up and made arable, not only has the soil been enriched by the death and slow decay of the plants which have left soluble matters in the soil; but the leaves and roots of the grasses living at the time and occupying so large a part of the surface, afford saccharine, mucilaginous, and extractive matters, which become immediately the food of the crop, and the gradual decomposition affords a supply for successive years.

Rape cake, which is used with great success as a manure, contains a large quantity of mucilage, some albuminous matter, and a small quantity of oil. This manure should be used recent, and kept as dry as possible before it is applied. It forms an excellent dressing for turnip crops; and is most economically applied by being thrown into the soil at the same time with the seed. Whoever wishes to see this practice in its highest degree of perfection, should attend Mr. Coke's annual sheep-shearing at Holkham.

Malt dust consists chiefly of the infant radicle separated from the grain. I have never made any experiment upon this manure; but there is great reason to suppose it must contain saccharine matter; and this will account for it powerful effects. Like rape cake, it should be used as dry as possible, and its fermentation prevented.

Linseed cake is too valuble as a food for cattle to be much employed as a manure; the analysis of linseed was referred to in the third lecture. The *water* in which *flax* and *hemp* are steeped for the purpose of obtaining the pure vegetable fibre, has considerable fertilizing powers. It appears to contain a substance analogous to albumen, and likewise much vegetable extractive matter. It putrefies very readily. A certain degree of fermentation is absolutely necessary to obtain the flax and hemp in a proper state; the water to which they have been exposed should therefore be used as a manure as soon as the vegetable fibre is removed from it.

Sea weeds, consisting of different species of fuci, algæ, and confervæ, are much used as a manure on the sea-coasts of Britain and Ireland. By digesting the common fucus, which is the sea-weed usually most abundant on the coast, in boiling water, I obtained from it one-eighth of a gelatinous substance which had characters similar to mucilage. A quantity distilled gave nearly four-fifths of its weight of water, but no ammonia; the water had an empyreumatic and slightly sour taste; the ashes contained sea salt, carbonate of soda, and carbonaceous matter. The gaseous matter afforded was small in quantity, principally carbonic acid and gaseous oxide of carbon, with a little hydro-carbonate. This manure is transient in this effects, and does not last for more than a single crop, which is easily accounted for from the large quantity of water, or the elements of water, it contains. It decays without producing heat when exposed to the atmosphere, and seems as it were to melt down and dissolve away. I have seen a large heap entirely destroyed in less than two years, nothing remaining but a little black fibrous matter.

I suffered some of the firmest part of a fucus to remain in a close jar containing atmospheric air for a fortnight: in this time it had become very much shrivelled; the sides of the jar were lined with dew. The air examined was found to have lost oxygen, and contained carbonic acid gas.

Sea-weed is sometimes suffered to ferment before it is used; but this process seems wholly unnecessary, for there is no fibrous matter rendered soluble in the process, and a part of the manure is lost.

The best farmers in the west of England use it as fresh as it can be procured; and the practical results of this mode of applying it are exactly conformable to the theory of its operation. The carbonic acid formed by its incipient fermentation must be partly dissolved by the water set free in the same process; and thus become capable of absorption by the roots of plants.

The effects of the sea-weed as manure must principally depend upon this carbonic acid, and upon the soluble mucilage the weed contains; and I found that some fucus which had fermented so as to have lost about half its weight, afforded less than $\frac{1}{12}$ of mucilaginous matter; from which it may be fairly concluded that some of this substance is destroyed in fermentation.

Dry straw of wheat, oats, barley, beans and peas, and spoiled hay, or any other similar kind of dry vegetable matter, is, in all cases, useful manure. In general, such substances are made to ferment before they are employed, though it may be doubted whether the practice should be indiscriminately adopted.

From 400 grains of dry barley straw I obtained eight grains of matter soluble in water, which had a brown color, and tasted like mucilage. From 400 grains of wheaten straw I obtained five grains of a similar substance.

There can be no doubt that the straw of different crops immediately ploughed into the ground affords nourishment to plants; but there is an objection to this method of using straw, from the difficulty of burying long straw, and from its rendering the husbandry foul.

When straw is made to ferment, it becomes a more manageable manure; but there is likewise on the whole a great loss of nutritive matter. More manure is perhaps supplied for a single crop; but the land is less improved than it would be, supposing the whole of the vegetable matter could be finely divided and mixed with the soil.

It is usual to carry straw that can be employed for no other purpose to the dunghill to ferment and decompose, but it is worth experiment, whether it may not be more economically applied when chopped small by a proper machine, and kept dry till it is ploughed in for the use of a crop. In this case, though it would decompose much more slowly, and produce less effect at first, yet its influence would be much more lasting.

Mere woody fibre seems to be the only vegetable matter that requires fermentation to render it nutritive to plants. Tanners' *spent bark* is a substance of this kind. Mr. Young, in his excellent Essay on Manures, which gained him the Bedfordian medal of the Bath Agricultural Society, states, "that spent bark seemed rather to injure than assist vegetation;" which he attributes to the astrigent matter that it contains. But in fact it is freed from all soluble substances, by the operation of water in the tan-pit; and if injurious to vegetation, the effect is probably owing to its agency upon water, or to its mechanical effects. It is a substance very absorbent and retentive of moisture, and yet not penetrable by the roots of plants.

Inert peaty matter is a substance of the same kind. It remains for years exposed to water and air without undergoing change; and in this state yields little or no nourishment to plants.

Woody fibre will not ferment unless some substances are mixed with it which act the same part as the mucilage, sugar, and extractive or albuminous matters, with which it is usually associated in herbs and succulent vegetables. Lord Meadowbank has judiciously recommended a mixture of common farm-yard dung for the purpose of bringing peas into fermentation; any putrescible or fermentable substance will answer the end; and the more a substance heats, and the more readily it ferments, the better will it be fitted for the purpose.

Lord Meadowbank states, that one part of dung is sufficient to bring three or four parts of peat into a state in which it is fitted to be applied to land; but of course the quantity must vary according to the nature of the dung and of the peat. In cases in which some living vegetables are mixed with the peat, the fermentation will be more readily effected.

Tanners' spent bark, shavings of wood and sawdust, will probably require as much dung to bring them into fermentation, as the worst kind of peat.

Woody fibre may be likewise prepared so as to become a manure by the action of lime. This subject I shall discuss in the next lecture, as it follows naturally another series of facts relating to the effects of lime in the soil.

It is evident from the analysis of woody fibre by MM. Gay Lussac and Thenard, (which shows that it consists principally of the elements of water and carbon, the carbon being in larger quantity than in the other vegetable compounds), that any process which tends to abstract carbonaceous matter from it must bring it nearer in composition to the soluble principles; and this is done in fermentation by the absorption of oxygen and production of carbonic acid; and a similar effect, it will be shown, is produced by lime.

Wood-ashes imperfectly formed, that is, wood-ashes containing much charcoal, are said to have been used with success as a manure. A part of their effects may be owing to the slow and gradual consumption of the charcoal, which seems capable, under other circumstances than those of actual combustion, of absorbing oxygen so as to become carbonic acid.

In April, 1803, I inclosed some well burnt charcoal in a tube half filled with pure water, and half with common air; the tube was hermetically sealed. I opened the tube under pure water in the spring of 1804, at a time when the atmospheric temperature and pressure were nearly the same as at the commencement of the experiment. Some water rushed in; and on expelling a little air by heat from the tube, and analyzing it, it was found to contain only seven per cent. of oxygen. The water in the tube, when mixed with lime-water, produced a copious precipitate; so that carbonic acid had evidently been formed and dissolved by the water.

Manures from animal substances, in general, require no *chemical* preparation to fit them for the soil. The great object of the farmer is to blend them with the earthy constituents in a proper state of division, and to prevent their too rapid decomposition.

The entire parts of the muscles of land animals are not commonly used as a manure, though there are many cases in which such an application might be easily made. Horses, dogs, sheep, deer, and other quadrupeds that have died accidentally, or of disease, after their skins are separated are often suffered to remain exposed to the air, or immersed in water, till they are destroyed by birds or beasts of prey, or entirely decomposed; and in this case most of their organized matter is lost for the land in which they lie, and a considerable portion of it employed in giving off noxious gases to the atmosphere.

By covering dead animals with five or six times their bulk of soil, mixed with one part of lime, and suffering them to remain for a few months, their decomposition would impregnate the soil with soluble matters, so as to render it an excellent manure, and by mixing a little fresh quicklime with it at the time of its removal the disagreeable effluvia would be in a great measure destroyed; and it might be applied in the same way as any other manure to crops.

Fish forms a powerful manure, in whatever state it is applied; but it cannot be ploughed in too fresh, though the quantity should be limited. Mr. Young records an experiment, in which herrings spread over a field and ploughed in for wheat, produced so rank a crop that it was entirely laid before harvest.

The refuse pilchards in Cornwall are used throughout the county as a manure, with excellent effects. They are usually mixed with sand or soil, and sometimes with sea-weed, to prevent them from raising too luxuriant a crop. The effects are perceived for several years.

In the fens of Lincolnshire, Cambridgeshire, and Norfolk, the little fish called sticklebacks, are caught in the shallow waters in such quantities, that they form a great article of manure in the land bordering on the fens.

It is easy to explain the operation of fish as a manure. The skin is principally gelatine; which from its slight state of cohesion is readily soluble in water: fat or oil is always found in fishes, either under the skin or in some of the viscera; and their fibrous matter contains all the essential elements of vegetable substances.

Amongst oily substances, *blubber* has been employed as manure. It is most useful when mixed with clay, sand, or any common soil, so as to expose a large surface to the air, the oxygen of which produces soluble matter from it. Lord Somerville used blubber with great success at his farm in Surrey. It was made into a heap with soil, and retained its powers of fertilizing for several successive years.

The carbon and hydrogen abounding in oily substances fully account for their effects; and their durability is easily explained from the gradual manner in which they change by the action of air and water.

Bones are much used as a manure in the neighborhood of London. After being broken and boiled for grease, they are sold to the farmer. The more divided they are, the more powerful are their effects. The expense of grinding them in a mill would probably be repaid by the increase of their fertilizing powers; and in the state of powder they might be used in the drill husbandry, and delivered with the seed in the same manner as rape cake.

Bone dust and bone shavings, the refuse of the turning manufacture, may be advantageously employed in the same way.

The basis of bone is constituted by earthy salts, principally phosphate of lime, with some carbonate of lime and phosphate of magnesia; the easily decomposable substances in bone are fat, gelatine, and cartilage, which seem of the same nature as coagulated albumen.

According to the analysis of Fourcroy and Vauquelin, ox bones are composed,

Of decomposable animal matter	51
— phosphate of lime	37·7
— carbonate of lime	10
— phosphate of magnesia	1·3
	100

M. Merat Guillot has given the following estimate of the composition of the bones of different animals:—

	Phosphate of Lime.	Carbonate of Lime.
Bone of Calf	54	
—— Horse	67·5	1·25
—— Sheep	70	5
—— Elk	90	1
—— Hog	52	1
—— Hare	85	1
—— Pullet	72	1·5
—— Pike	64	1
—— Carp	45	5
Horses' teeth	85·5	25
Ivory	64	1

The remaining parts of the hundred must be considered as decomposable animal matter.

Horn is a still more powerful manure than bone, as it contains a larger quantity of decomposable animal matter. From 500 grains of ox horn Mr. Hatchett obtained only 1·5 grains of earthy residuum, and not quite half of this was phosphate of lime. The shavings or turnings of horn form an excellent manure, though they are not sufficiently abundant to be in common use. The animal matter in them seems to be of the nature of coagulated albumen, and it is slowly rendered soluble by the action of water. The earthy matter in horn, and still more that in bones, prevents the too rapid decomposition of the animal matter, and renders it very durable in its effects.

Hair, *woollen rags*, and *feathers*, are all analogous in composition, and principally consist of a substance similar to albumen, united to gelatine. This is shown by the ingenious researches of Mr. Hatchett. The theory of their operation is similar to that of bone and horn shavings.

The *refuse* of the different manufactures of *skin* and *leather* form very useful manures; such as the shavings of the currier, furriers' clippings, and the offals of the tan-yard and of the glue-maker. The gelatine contained in every kind of skin is in a state fitted for its gradual solution or decomposition; and when buried in the soil, it lasts for a considerable time, and constantly affords a supply of nutritive matter to the plants in its neighborhood.

Blood contains certain quantities of all the principles found in other animal substances, and is consequently a very good manure. It has been already stated that it contains fibrine; it likewise contains albumen: the red particles in it, which have been supposed by many foreign chemists to be colored by iron in a particular state of combination with oxygen and acid matter, Mr. Brande considers as formed of a peculiar animal substance, containing very little iron.

The scum taken from the boilers of the sugar bakers, and which is used as manure, principally consists of bullock's blood, which has been employed for the purpose of separating the impurities of common brown sugar, by means of the coagulation of its albuminous matter by the heat of the boiler.

The different species of *corals*, *corallines*, and *sponges*, must be considered as substances of animal origin. From the analysis of Mr. Hatchett, it appears that all these substances contain considerable quantities of a matter analogous to coagulated albumen; the sponges afford likewise gelatine.

According to Merat Guillot, white coral contains equal parts of animal matter and carbonate of lime; red coral 46·5 of animal matter, and 53·5 of carbonate of lime; articulated coralline 51 of animal matter, and 49 of carbonate of lime.

These substances are, I believe, never used as manure in this country, except in cases when they are accidentally mixed with sea-weed; but it is probable that the corallines might be advantageously employed, as they are found in considerable quantity on the rocks and bottoms of the rocky pools in many parts of our coast, where the land gradually declines towards the sea; and they might be detached by hoes, and collected without much trouble.

Amongst excrementitious animal substances used as manures, *urine* is the one upon which the greatest number of chemical experiments have been made, and the nature of which is best understood.

The urine of the crow contains, according to the experiments of Mr. Brande,

Of water	65
— phosphate of lime	3
— muriates of potassa and ammonia	15
— sulphate of potassa	6
— carbonates of potassa, and ammonia	4
— urea	4

The urine of the horse, according to Fourcroy and Vauquelin, contains

Of carbonate of lime	11
— carbonate of soda	9
— benzoate of soda	24
— muriate of potassa	9
— urea	7
— water and mucilage	940

In addition to these substances, Mr. Brande found in it phosphate of lime.*

The urine of the ass, the camel, the rabbit, and domestic fowls has been submitted to different experiments, and the constitution has been found similar. In the urine of the rabbit, in addition to most of the ingredients above mentioned, Vauquelin detected gelatine; and the same chemist discovered uric acid in the urine of domestic fowls.†

Human urine contains a greater variety of constituents than any other species examined.

Urea, uric acid, and another acid similar to it in nature, called rosacic acid, acetic acid, albumen, gelatine, a resinous matter, and various salts, are found in it.

The human urine differs in composition according to the state of the body, and the nature of the food and drink made use of. In many cases of disease there is a much larger quantity of gelatine and albumen than usual in the urine; and in diabetes it contains sugar.

It is probable that the urine of the same animal must likewise differ according to the different nature of the food and drink used; and this will account for discordances in some of the analyses that have been published on the subject.

Urine is very liable to change and to undergo the putrefactive process; and that of carnivorous animals more rapidly than that of graminivorous animals. In proportion as there is more gelatine and albumen in urine, so in proportion does it putrefy more quickly.

The species of urine that contain most albumen, gelatine, and urea, are the best as manures; and all urine contains the essential elements of vegetables in a state of solution.

During the putrefaction of urine the greatest part of the soluble animal matter that it contains is destroyed; it should consequently be used as fresh as possible; but if not mixed with solid matter, it should be diluted with water, as when pure it contains too large a quantity of animal matter to form a proper fluid nourishment for absorption by the roots of plants.

Putrid urine abounds in ammoniacal salts; and though less active than fresh urine, is a very powerful manure.

* This has not been confirmed by Chevreul. In trials made expressly for the purpose, he was not able to detect phosphate of lime, either in the urine of the horse or of the camel.

† The urine of the mammalia generally abounds most in urea; of birds and reptiles, in uric acid: the urine of the frog and toad, however, are exceptions; their urine is fluid, and not in part solid, like that of birds and reptiles, and contains a large proportion of urea. —J. D.

According to a recent analysis published by Berzelius, 1000 parts of urine are composed of

Water	933
Urea	30.1
Uric acid	1
Muriate of ammonia, free lactic acid, lactate of ammonia, and animal matter	17·14

The remainder different salts, phosphates, sulphates, and muriates.

Amongst excrementitious solid substances used as manures, one of the most powerful is the *dung* of *birds* that feed on *animal food*, particularly the dung of sea birds. The *guano*, which is used to a great extent in South America, and which is the manure that fertilizes the steril plains of Peru, is a production of this kind. It exists abundantly, as we are informed by M. Humboldt, on the small islands in the South Sea, at Chinche, Ilo, Iza, and Arica. Fifty vessels are laden with it annually at Chinche, each of which carries from 1500 to 2000 cubical feet. It is used as a manure only in very small quantities; and particularly for crops of maize. I made some experiments on specimens of guano sent from South America to the Board of Agriculture in 1805. It appeared as a fine brown powder; it blackened by heat, and gave off strong ammoniacal fumes: treated with nitric acid, it afforded uric acid. In 1806 MM. Fourcroy and Vauquelin published an elaborate analysis of guano. They state that it contains a fourth part of its weight of uric acid, partly saturated with ammonia, and partly with potassa; some phosphoric acid combined with the same bases, and likewise with lime, small quantities of sulphate and muriate of potassa, a little fatty matter, and some quartzose sand.

It is easy to explain its fertilizing properties: from its composition it might be supposed to be a very powerful manure. It requires water for the solution of its soluble matter, to enable it to produce its full beneficial effect on crops.

The dung of sea birds has, I believe, never been used as a manure in this country: but it is probable that even the soil of the small islands on our coast much frequented by them would fertilize. Some dung of sea birds brought from a rock on the coast of Merionethshire produced a powerful but transient effect on grass. It was tried, at my request, by Sir Robert Vaughan at Nannau.

The rains in our climate must tend very much to injure this species of manure, where it is exposed to them, soon after its deposition; but it may probably be found in great perfection in caverns or clefts in rocks, haunted by cormorants and gulls. I examined some recent cormorant's dung which I found on a rock near Cape Lizard in Cornwall. It had not at all the appearance of the guano; was of a grayish-white color; had a very fœtid smell, like that of putrid animal matter; when acted on by quicklime, it gave abundance of ammonia; treated with nitric acid, it yielded uric acid.

Night-soil, it is well known is a very powerful manure, and very liable to decompose. It differs in its composition; but always abounds in substances composed of carbon, hydrogen, azote, and oxygen. From the analysis of Berzelius, it appears that a part of it is always soluble in water; and in whatever state it is used, whether recent or fermented, it supplies abundance of food to plants.

The disagreeable smell of night-soil may be destroyed by mixing it with quicklime; and if exposed to the atmosphere in thin layers strewed over with quicklime in fine weather, it speedily dries, is easily pulverized, and in this state may be used in the same manner as rape-cake, and delivered into the furrow with the seed.

The Chinese, who have more practical knowledge of the use and application of manures than any other people existing, mix their night-soil with one-third of its weight of a fat marl, make it into cakes, and dry it by exposure to the sun. These cakes, we are informed by the French missionaries, have no disagreeable smell, and form a common article of commerce of the empire.

The earth, by its absorbent powers, probably prevents, to a certain extent, the action of moisture upon the dung, and likewise defends it from the effects of air.

After night-soil, *pigeons' dung* comes next in order, as to fertilizing power. I digested 100 grains of pigeons' dung in hot water for some hours, and obtained from it 23 grains of soluble matter; which afforded abundance of carbonate of ammonia by distillation; and left carbonaceous matter, saline matter principally common salt, and carbonate of lime, as a residuum. Pigeons' dung, when moist, readily ferments, and after fermentation contains less soluble matter than before: from 100 parts of fermented pigeons' dung, I obtained only eight parts of soluble matter, which gave proportionally less carbonate of ammonia in distillation than recent pigeons' dung.

It is evident that this manure should be applied as new as possible; and when dry, it may be employed in the same manner as the other manures capable of being pulverized.

The soil in woods where great flocks of wood-pigeons roost is often highly impregnated with their dung, and, it cannot be doubted, would form a valuable manure. I have found such soil yield ammonia when distilled with lime. In the winter, likewise, it usually contains abundance of vegetable matter, the remains of decayed leaves; and the dung tends to bring the vegetable matter into a state of solution.

The dung of *domestic fowls* approaches very nearly in its nature to pigeons' dung. Uric acid has been found in it. It gives carbonate of ammonia by distillation, and immediately yields soluble matter to water. It is very liable to ferment.

The dung of fowls is employed in common with that of pigeons by tanners to bring on a slight degree of putrefaction in skins that are to be used for making soft leather; for this purpose the dung is diffused through water. In this state, it rapidly undergoes putrefaction, and brings on a similar change in the skin. The excrements of dogs are employed by the tanner with similar effects. In all cases, the contents of the *grainer*, as the pit is called in which soft skins are prepared by dung, must form a very useful manure.

Rabbits' dung has never been analyzed. It is used with great success as a manure by Mr. Fane, who finds it profitable to keep rabbits in such a manner as to preserve their dung. It is laid on as fresh as possible, and is found better the less it has fermented.

The *dung* of *cattle*, *oxen*, and *cows*, has been chemically examined by MM. Einhof and Thaer. They found that it contained matter soluble in water; and that it gave in fermentation nearly the same products as vegetable substances, absorbing oxygen, and producing carbonic acid gas.

The recent *dung* of *sheep* and of *deer*, afford, when long boiled in water, soluble matters, which equal from two to three per cent. of their weight. I have examined these soluble substances procured by solution and evaporation: they contain a very small quantity of matter analogous to animal mucus; and are principally composed of a bitter extract soluble both in water and in alcohol. They give ammoniacal fumes by distillation; and appear to differ very little in composition.

I watered some blades of grass for several successive days with a solution of these extracts; they evidently became greener in consequence, and grew more vigorously than grass in other respects under the same circumstances.

The part of the dung of cattle, sheep and deer, not soluble in water; appears to be mere woody fibre, and precisely analogous to the residuum of those vegetables that form their food after they have been deprived of all their soluble materials.

The dung of horses gives a brown fluid, which, when evaporated, yields a bitter extract, which affords ammoniacal fumes more copiously than that from the dung of oxen.

If the pure dung of cattle is to be used as manure, like the other species of dung which have been mentioned, there seems no reason why it should be made to ferment, except in the soil; or if suffered to ferment, it should be only in a very slight degree. The grass in the neighborhood of recently voided dung is always coarse and dark green; some persons have attributed this to a noxious quality in unfermented dung; but it seems to be rather the result of an excess of food furnished to the plants.

The question of the proper mode of the application of the dung of horses and cattle, however, properly belongs to the subject of *composite manures*, for it is usually mixed in the farm-yard with straw, offal, chaff, and various kinds of litter; and itself contains a large proportion of fibrous vegetable matter.

A slight incipient fermentation is undoubtedly of use in the dunghill; for by means of it a disposition is brought on in the woody fibre to decay and dissolve, when it is carried to the land, or ploughed into the soil; and woody fibre is always in great excess in the refuse of the farm.

Too great degree of fermentation is, however, very prejudicial to the composite manure in the dunghill; it is better that there should be no fermentation at all before the manure is used, than that it should be carried too far. This must be obvious from what has been already stated in this lecture. The excess of fermentation tends to the destruction and dissipation of the most useful part of the manure; and the ultimate results of this process are like those of combustion.

It is a common practice amongst farmers to suffer the farm-yard dung to ferment till the fibrous texture of the vegetable matter is entirely broken down, and till the manure becomes perfectly cold, and so soft as to be easily cut by the spade.

Independent of the general theoretical views unfavorable to this practice founded upon the nature and composition of vegetable substances, there are many arguments and facts which show that it is prejudicial to the interests of the farmer.

During the violent fermentation which is necessary for reducing farm-yard manure to the state in which it is called *short muck*, not only a large quantity of fluid, but likewise of gaseous matter, is lost; so much so, that the dung is reduced one-half, or two-thirds in weight; and the principal elastic matter disengaged is carbonic acid, with some ammonia; and both these, if retained by the moisture in the soil, as has been stated before, are capable of becoming a useful nourishment of plants.

In October, 1808, I filled a large retort, capable of containing three pints of water, with some hot fermenting manure, consisting principally of the litter and dung of cattle; I adapted a small receiver to the retort, and connected the whole with a mercurial pneumatic apparatus, so as to collect the condensible and elastic fluids which might rise from the dung. The receiver soon became lined with dew, and drops began in a few hours to trickle down the sides of it. Elastic fluid likewise was generated; in three days 35 cubical inches had been formed, which, when analyzed, were found to contain 21 cubical inches of carbonic acid; the remainder was hydrocarbonate mixed with some azote, probably no more than existed in the common air in the receiver. The fluid matter collected in the receiver at the same time amounted to nearly half an ounce. It had a saline taste, and a disagreeable smell, and contained some acetate and carbonate of ammonia.

Finding such products given off from fermenting litter, I introduced the beak of another retort, filled with similar dung very hot at the time, into the soil amongst the roots of some grass in the border of a garden; in less than a week a very distinct effect was produced on the grass; upon the spot exposed to the influence of the matter disengaged in fermentation, it grew with much more luxuriance than the grass in any other part of the garden.

Besides the dissipation of gaseous matter when fermentation is pushed to the extreme, there is another disadvantage in the loss of *heat*, which, if excited in the soil, is useful in promoting the germination of the seed, and in assisting the plant in the first stage of its growth, when it is most feeble and most liable to disease: and the fermentation of manure in the soil must be particularly favorable to the wheat crop in preserving a genial temperature beneath the surface late in autumn, and during winter.

Again, it is a general principle in chemistry, that in all cases of decomposition, substances combine much more readily at the moment of their disengagement, than after they have been perfectly formed. And in fermentation beneath the soil, the fluid matter produced is applied instantly, even whilst it is warm, to the organs of the plant, and consequently, is more likely to be efficient than in manure that has gone through the process, and of which all the principles have entered into new combinations.

In the writings of scientific agriculturists, a great mass of facts may be found in favor of the application of farm-yard dung in a recent state. Mr. Young, in the essay on manures, which I have already quoted, adduces a number of excellent authorities in support of the plan. Many who doubted have been lately convinced; and perhaps there is no subject of investigation in which there is such a union of theoretical and practical evidence. I have myself within the last ten years witnessed a number of distinct proofs on the subject. I shall content myself with quoting that which ought to have, and which I am sure will have, the greatest weight among agriculturists. Within the last seven years, Mr. Coke has entirely given up the system formerly adopted on his farm, of applying fermented dung; and he informs me that his crops have been since as good as they ever were, and that his manure goes nearly twice as far.

A great objection against slightly fermented dung, is, that weeds spring up more luxuriantly where it is applied. If there are seeds carried out in the dung, they certainly will germinate; but it is seldom that this can be the case to any extent; and if the land is not cleansed of weeds, any kind of manure fermented or unfermented will occasion their rapid growth. If slightly fermented farm-yard dung is used as a top-dressing for pastures, the long straws and unfermented vegetable matter remaining on the surface should be removed as soon as the grass begins to rise vigorously by raking, and carried back to the dunghill: in this case no manure will be lost, and the husbandry will be at once clean and economical.

In cases when farm-yard dung cannot be immediately applied to crops, the destructive fermentation of it should be prevented as much as possible: the principles on which this may be effected have been already alluded to.

The surface should be defended as much as possible from the oxygen of the atmosphere; a compact marl, or a tenacious clay, offers the best protection against the air; and before the dung is covered over, or, as it were, sealed up, it should be dried as much as possible. If the dung is found at any time to heat strongly, it should be turned over, and cooled by exposure to air.

Watering dunghills is sometimes recommended for checking the progress of fermentation; but this practice is inconsistent with just chemical views. It may cool the dung for a short time; but moisture, as I have before stated, is a principal agent in all processes of decomposition. Dry fibrous matter will never ferment. Water is as necessary as air to the process; and to supply it to fermenting dung, is to supply an agent which will hasten its decay.

In all cases when dung is fermenting, there are simple tests by which the rapidity of the process, and consequently the injury done, may be discovered.

If a thermometer plunged into the dung does not rise to above 100 degrees of Fahrenheit, there is little danger of much aëriform matter flying off. If the temperature is higher, the dung should be immediately spread abroad.

When a piece of paper, moistened in muriatic acid, held over the steams arising from a dunghill, gives dense fumes, it is a certain test that the decomposition is going too far; for this indicates that volatile alkali is disengaged.

When dung is to be preserved for any time, the situation in which it is kept is of importance. It should, if possible, be defended from the sun. To preserve it under sheds would be of great use; or to make the site of a dunghill on the north side of a wall. The floor on which the dung is heaped should, if possible, be paved with flat stones; and there should be a little inclination from each side towards the centre, in which there should be drains connected with a small well, furnished with a pump, by which any fluid matter may be collected for the use of the land. It too often happens that a dense mucilaginous and extractive fluid is suffered to drain away from the dunghill, so as to be entirely lost to the farm.*

Street and *road dung*, and the *sweepings of houses*, may be all regarded as composite manures; the constitution of them is necessarily various, as they are derived from a number of different substances. These manures are usually applied in a proper manner, without being fermented.

Soot, which is principally formed from the combustion of pit-coal or coal, generally contains likewise substances derived from animal matters. This is a very powerful manure. It affords ammoniacal salts by distillation, and yields a brown extract to hot water, of a bitter taste. It likewise contains an empyreumatic oil. Its basis is charcoal, in a state in which it is capable of being rendered soluble by the action of oxygen and water.

This manure is well fitted to be used in the dry state, thrown into the ground with the seed, and requires no preparation.

The doctrine of the proper application of manures from organized substances offers an illustration of an important part of the economy of nature, and of the happy order in which it is arranged.

The death and decay of animal substances tend to resolve organized forms into chemical constituents; and the pernicious effluvia disengaged in the process seem to point out the propriety of burying them in the soil, where they are fitted to become the food of vegetables. The fermentation and putrefaction of organized substances in the free atmosphere are noxious processes; beneath the surface of the ground, they are salutary operations. In this case the food of plants is prepared where it can be used; and that which would offend the senses and injure the health, if exposed, is converted by gradual processes into forms of beauty and of usefulness; the fœtid gas is rendered a constituent of the aroma of the flower, and what might be poison becomes nourishment to animals and to man.

LECTURE VII.

ON MANURES OF MINERAL ORIGIN, OR FOSSIL MANURES; THEIR PREPARATION, AND THE MANNER IN WHICH THEY ACT. OF LIME IN ITS DIFFERENT STATES; OPERATION OF LIME AS A MANURE AND A CEMENT; DIFFERENT COMBINATIONS OF LIME. OF GYPSUM; IDEAS RESPECTING ITS USE. OF OTHER NEUTRO-SALINE COMPOUNDS, EMPLOYED AS MANURES. OF ALKALIES AND ALKALINE SALTS; OF COMMON SALT.

The whole tenor of the preceding lectures shows that a great variety of substances contributes to the growth of plants, and supplies the materials of their nourishment. The conversion of matter that has belonged to living structures into organized forms is a process than can be easily understood; but it is more difficult to follow those operations by which earthy and saline matters are consolidated in the fibre of plants, and by which they are made subservient to their functions. Some inquirers, adopting that sublime generalization of the ancient philosophers that matter is the same in essence, and that the different substances considered as elements by chemists are merely different arrangements of the same indestructible particles, have endeavored to prove that all the varieties of the principles found in plants may be formed from the substances in the atmosphere; and that vegetable life is a process in which bodies that the analytical philosopher is unable to change or to form are constantly composed and decomposed. These opinions have not been advanced merely as hypotheses; attempts have been made to support them by experiments. M. Schrader and Mr. Braconnot, from a series of distinct investigations, have arrived at the same conclusions. They state that different seeds sown in fine sand, sulphur, and metallic oxides, and supplied only with atmospherical air and water, produced healthy plants, which by analysis yielded various earthy and saline matters, which either were not contained in the seeds or the material in which they grew, or which were contained only in much smaller quantities in the seeds: and hence they conclude that they must have been formed from air or water, in consequence of the agencies of the living organs of the plant.

The researches of these two gentlemen were conducted with much ingenuity and address; but there were circumstances which interfered with their results, which they could not have known, as at the time their labors were published they had not been investigated.

I have found that common distilled water is far from being free from saline impregnations. In analyzing it by Voltaic electricity, I procured from it alkalies and earths; and many of the combinations of metals with chlorine are extremely volatile substances. When distilled water is supplied in an unlimited manner to plants, it may furnish to them a number of different substances, which, though in quantities scarcely perceptible in the water, may accumulate in the plant, which probably perspires only absolutely pure water.

In 1801 I made an experiment on the growth of oats, supplied with a limited quantity of distilled water in a soil composed of pure carbonate of lime. The soil and the water were placed in a vessel of iron, which was included in a large jar, connected with the free atmosphere by a tube, so curved as to prevent the possibility of any dust, or fluid, or solid matter from entering into the jar. My object was to ascertain whether any siliceous earth

* The state in which farm-yard manure should be used is still a *questio vexata*; and is likely to remain so, till an extensive series of judicious experiments shall have been made on the subject by competent persons, equally qualified by theoretical and practical knowledge to arrive at precise results, and to be able to communicate them. The question, in all its relations, is necessarily one of extreme difficulty, as well as of importance. Probably composts, or mixtures of stable and farm-yard manure, with marl, clay, or lime, according to circumstances, will prove most advantageous of all, if kept well covered with earth, so as to allow of a certain degree of fermentation, and yet prevent any material loss of gaseous matter.—J. D.

would be formed in the process of vegetation; but the oats grew very feebly, and began to be yellow before any flowers formed: the entire plants were burnt, and their ashes compared with those from an equal number of grains of oat. Less siliceous earth was given by the plants than by the grains; but their ashes yielded much more carbonate of lime. That there was less siliceous earth, I attribute to the circumstance of the husk of the oat being thrown off in germination; and this is the part which most abounds in silica. Healthy green oats, taken from a growing crop, in a field of which the soil was a fine sand, yielded siliceous earth in a much greater proportion than an equal weight of the corn artificially raised.

The general results of this experiment are very much opposed to the idea of the composition of the earths, by plants, from any of the elements found in the atmosphere, or in water; and there are other facts contradictory to the idea. Jacquin states that the ashes of glass wort (*salsola soda*,) when it grows in inland situations, afford the vegetable alkali; when it grows on the sea-shore, where compounds which afford the fossil or marine alkali are more abundant, it yields that substance. Du Hamel found that plants which usually grow on the sea-shore, made small progress when planted in soils containing little common salt. The sun-flower, when growing in lands containing no nitre, does not afford that substance; though when watered by a solution of nitre, it yields nitre abundantly. The tables of De Saussure, referred to in the third lecture, show that the ashes of plants are similar in constitution to the soils in which they have vegetated.

De Saussure made plants grow in solutions of different salts, and he ascertained that in all cases certain portions of the salts were absorbed by the plant, and found unaltered in their organs.

Even animals do not appear to possess the power of forming the alkaline and earthy substances. Dr. Fordyce found, that when canary birds, at the time they were laying eggs, were deprived of access to carbonate of lime, their eggs had soft shells; and if there is any process for which nature may be conceived most likely to supply resources of this kind, it is that connected with the reproduction of the species.

As the evidence on the subject now stands, it seems fair to conclude, that the different earths and saline substances found in the organs of plants are supplied by the soils in which they grow; and in no cases composed by new arrangements of the elements in air or water. What may be our ultimate view of the laws of chemistry, or how far our ideas of elementary principles may be simplified, it is impossible to say. We can only reason from facts. We cannot imitate the powers of composition belonging to vegetable structures; but at least we can understand them: and, as far as our researches have gone, it appears that in vegetation compound forms are uniformly produced from simpler ones; and the elements in the soil, the atmosphere, and the earth, absorbed and made parts of beautiful and diversified structures.

The views which have been just developed lead to correct ideas of the operation of these manures, which are not necessarily the result of decayed organized bodies, and which are not composed of different proportions of carbon, hydrogen, oxygen, and azote. They must produce their effect, either by becoming a constituent part of the plant, or by acting upon its more essential food, so as to render it more fitted for the purposes of vegetable life.

The only substances which can with propriety be called fossil manures, and which are found unmixed with the remains of any organized beings, are certain alkaline earths, or alkalies, and their combinations.

The only alkaline earths which have been hitherto applied in this way, are lime and magnesia. Potassa and soda, the two fixed alkalies, are both used in certain of their chemical compounds. I shall state in succession such facts as have come to my knowledge respecting each of these bodies in their applications to the purposes of agriculture; but I shall enlarge most upon the subject of lime; and if I should enter into some details which may be tedious and minute, I trust, my excuse will be found in the importance of the inquiry; and it is one which has been greatly elucidated by late discoveries.

The most common form in which lime is found on the surface of the earth, is in a state of combination with carbonic acid or fixed air. If a piece of limestone, or chalk, be thrown into a fluid acid, there will be an effervescence. This is owing to the escape of the carbonic acid gas. The lime becomes dissolved in the liquor.

When limestone is strongly heated, the carbonic acid gas is expelled, and then nothing remains but the pure alkali earth: in this case there is a loss of weight; and if the fire has been very high, it approaches to one-half the weight of the stone; but in common cases, limestones, if well dried before burning, do not lose much more than from 30 to 40 per cent., or from seven to eight parts out of 20.

I mentioned, in discussing the agencies of the atmosphere upon vegetables, in the beginning of the fifth lecture, that air always contains carbonic acid gas, and that lime is precipitated from water by this substance. When burnt lime is exposed to the atmosphere, in a certain time it becomes mild, and is the same substance as that precipitated from lime-water; it is combined with carbonic acid gas. Quicklime, when first made, is caustic and burning to the tongue, renders vegetable blues green, and is soluble in water; but when combined with carbonic acid it loses all these properties, its solubility, and its taste: it regains its power of effervescing, and becomes the same chemical substance as chalk or limestone.

Very few limestones or chalks consist entirely of lime and carbonic acid. The statuary marbles or certain of the rhomboidal spars, are almost the only pure species; and the different properties of limestones, both as manures and cements, depend upon the nature of the ingredients mixed in the limestone; for the true calcareous element, the carbonate of lime, is uniformly the same in nature, properties, and effects, and consists of one proportion of carbonic acid 41·4, and one of lime 55.

When a limestone does not copiously effervesce in acids, and is sufficiently hard to scratch glass, it contains siliceous, and probably aluminous earth. When it is deep brown or red, or strongly colored of any of the shades of brown or yellow, it contains oxide of iron. When it is not sufficiently hard to scratch glass, but effervesces slowly, and makes the acid in which it effervesces milky, it contains magnesia. And when it is black and emits a fœtid smell if rubbed, it contains coally or bituminous matter.

The analysis of limestones is not a difficult matter; and the proportions of their constituent parts may be easily ascertained by the process described in the lecture on the analysis of soils; and usually with sufficient accuracy for all the purposes of the farmer, by the fifth process.

Before any opinion can be formed of the manner in which the different ingredients in limestones modify their properties, it will be necessary to consider the operation of the pure calcareous element as a manure, and as a cement.

Quicklime in its pure state, whether in powder or dissolved in water, is injurious to plants. I have in several instances killed grass by watering it with lime-water. But lime, in its state of combination with carbonic acid, as is evident from the analysis given in the fourth lecture, is a useful ingredient in soils. Calcareous earth is found in the ashes of the greater number of plants; and exposed to the air lime cannot long continue caustic, for the reasons that were just now assigned, but soon becomes united to carbonic acid.

When newly burnt lime is exposed to air, it soon falls into powder; in this case it is called slacked-lime; and the same effect is immediately produced by throwing water upon it, when it heats violently, and the water dissappears.

Slacked-lime is merely a combination of lime with about one-third of its weight of water; *i. e.* 55 parts of lime absorb 17 parts of water; and in this case it is composed of a definite proportion of lime to a definite proportion of water, and is called by chemists *hydrate of lime;* and when hydrate of lime becomes carbonate of lime by long exposure to air, the water is expelled, and the carbonic acid gas takes its place.

When lime, whether freshly burnt or slacked, is mixed with any moist fibrous vegetable matter, there is a strong action between the lime and the vegetable matter, and they form a kind of compost together, of which a part is usually soluble in water.

By this kind of operation, lime renders matter which was before comparatively inert nutritive; and as charcoal and oxygen abound in all vegetable matters, it becomes at the same time converted into carbonate of lime.

Mild lime, powdered limestone, marls or chalks, have no action of this kind upon vegetable matter; by their action they prevent the too rapid decomposition of substances already dissolved; but they have no tendency to form soluble matters

It is obvious from these circumstances, that the operation of quicklime, and marl or chalk, depends upon principles altogether different. Quicklime, in being applied to land, tends to bring any hard vegetable matter that it contains into a state of more rapid decomposition and solution, so as to render it a proper food for plants. Chalk, and marl, or carbonate of lime, will only improve the texture of the soil, or its relation to absorption: it acts merely as one of its earthy ingredients. Quicklime, when it becomes mild, operates in the same manner as chalk; but in the act of becoming mild, it prepares soluble out of insoluble matter.

It is upon this circumstance that the operation of lime in the preparation for wheat crops depends; and its efficacy in fertilizing peats, and in bringing into a state of cultivation all soils abounding in hard roots, or dry fibres, or inert vegetable matter.

The solution of the question, whether quicklime ought to be applied to a soil, depends upon the quantity of inert vegetable matter that it contains. The solution of the question, whether marl, mild lime, or powdered limestone, ought to be applied, depends upon the quantity of calcareous matter already in the soil. All soils are improved by mild lime, and ultimately by quicklime, which do not effervesce with acids; and sands more than clays.

When a soil, deficient in calcareous matter, contains much *soluble* vegetable manure, the application of quicklime should always be avoided, as it either tends to decompose the soluble matters by uniting to their carbon and oxygen so as to become mild lime, or it combines with the soluble matters, and forms compounds, having less attraction for water than the pure vegetable substance.

The case is the same with respect to most animal manures; but the operation of the lime is different in different cases, and depends upon the nature of the animal matter. Lime forms a kind of insoluble soap with oily matters, and then gradually decomposes them by separating from them oxygen and carbon. It combines likewise with the animal acids; and probably assists their decomposition by abstracting carbonaceous matter from them combined with oxygen: and consequently it must render them less nutritive. It tends to diminish likewise the nutritive powers of albumen from the same causes; and always destroys to a certain extent the efficacy of animal manures, either by combining with certain of their elements, or by giving to them new arrangements. Lime should never be applied with animal manures, unless they are too rich, or for the purpose of preventing noxious effluvia, as in certain cases mentioned in the last lecture. It is injurious when mixed with any common dung, and tends to render the extractive matter insoluble.

I made an experiment on this subject: I mixed a quantity of the brown soluble extract, which was procured from sheep's dung, with five times its weight of quicklime. I then moistened them with water; the mixture heated very much; it was suffered to remain for 14 hours, and was then acted on by six or seven times its bulk of pure water: the water, after being passed through a filter, was evaporated to dryness; the solid matter obtained was scarcely colored, and was lime mixed with a little saline matter.

In those cases in which fermentation is useful to produce nutriment from vegetable substances, lime is always efficacious. I mixed some moist tanners' spent bark with one-fifth of its weight of quicklime, and suffered them to remain together in a close vessel for three months; the lime had become colored, and was effervescent: when water was boiled upon the mixture, it gained a tint of fawn-color, and by evaporation furnished a fawn-colored powder, which must have consisted of lime united to vegetable matter, for it burnt when strongly heated, and left a residuum of mild lime.*

* The manner in which lime acts in agriculture requires further and minute investigation, and is a most important subject for inquiry. From the experiments

The limestones containing alumina and silica are less fitted for the purposes of manure than pure limestones; but the lime formed from them has no noxious quality. Such stones are less efficacious, merely because they furnish a smaller quantity of quicklime.

I mentioned bituminous limestones. There is very seldom any considerable portion of coally matter in these stones; never as much as five parts in 100; but such limestones make very good lime. The carbonaceous matter can do no injury to the land, and may, under certain circumstances, become a food of the plant, as is evident from what was stated in the last lecture.

The subject of the application of the magnesian limestone is one of great interest.

It had been long known to farmers in the neighborhood of Doncaster, that lime made from a certain limestone applied to the land often injured the crops considerably, as I mentioned in the introductory lecture. Mr. Tennant, in making a series of experiments upon this peculiar calcareous substance, found that it contained magnesia; and on mixing some calcined magnesia with soil in which he sowed different seeds, he found that they either died, or vegetated in a very imperfect manner, and the plants were never healthy. And with great justice and ingenuity he referred the bad effects of the peculiar limestone to the magnesian earth it contains.

In making some inquiries concerning this subject, I found that there were cases in which this magnesian limestone was used with good effect.

Amongst some specimens of limestone which Lord Somerville put into my hands, two marked as peculiarly good proved to be magnesian limestones. And lime made from the Breedon limestone is used in Leicestershire, where it is called hot lime; and I have been informed by farmers in the neighborhood of the quarry, that they employ it advantageously in small quantities, seldom more than 25 or 30 bushels to the acre. And that they find it may be used with good effect in larger quantities upon rich land.

A minute chemical consideration of this question will lead to its solution.

Magnesia has a much weaker attraction for carbonic acid than lime, and will remain in the state of caustic or calcined magnesia for many months, though exposed to the air. And as long as any caustic lime remains, the magnesia cannot be combined with carbonic acid, for lime instantly attracts carbonic acid from magnesia.

When a magnesian limestone is burnt, the magnesia is deprived of carbonic acid much sooner than the lime; and if there is not much vegetable or animal matter in the soil to supply by its decomposition carbonic acid, the magnesia will remain for a long while in the caustic state; and in this state acts as a poison to certain vegetables. And that more magnesian lime may be used upon rich soils, seems to be owing to the circumstance, that the decomposition of the manure in them supplies carbonic acid. And magnesia in its mild state, *i. e.* fully combined with carbonic acid, seems to be always a useful constituent of soils. I have thrown carbonate of magnesia (procured by boiling the solution of magnesia in super-carbonate of potassa) upon grass, and upon growing wheat and barley, so as to render the surface white: but the vegetation was not injured in the slightest degree. And one of the most fertile parts of Cornwall, the Lizard, is a district in which the soil contains mild magnesian earth.

The Lizard Downs bear a short and green grass; which feeds sheep, producing excellent mutton; and the cultivated parts are amongst the best corn lands in the country.

That the theory which I have ventured to give of the operation of magnesian lime is not unfounded, is shown by an experiment which I made expressly for the purpose of determining the true nature of the operation of this substance. I took four portions of the same soil: with one I mixed $\frac{1}{20}$ of its weight of caustic magnesia, with another I mixed the same quantity of magnesia and a proportion of a fat decomposing peat equal to one-fourth of the weight of the soil. One portion of soil remained in its natural state: and another was mixed with peat without magnesia. The mixtures were made in December 1806, and in April 1807 barley was sown in all of them. It grew very well in the pure soil; but better in the soil containing the magnesia and peat, and nearly as well in the soil containing peat alone: but in the soil containing the magnesia alone, it rose very feeble, and looked yellow and sickly.

I repeated this experiment in the summer of 1810 with similar results; and I found that the magnesia in the soil mixed with peat became strongly effervescent, whilst the portion in the unmixed soil gave carbonic acid in much smaller quantities. In the one case the magnesia had assisted in the formation of a manure, and had become mild; in the other case it had acted as a poison.

It is obvious, from what has been said, that lime from the magnesian limestone may be applied in large quantities to peats; and that where lands have been injured by the application of too large a quantity of magnesian lime, peat will be a proper and efficient remedy.

I mentioned that magnesian limestones effervesced little when plunged into an acid. A simple test of magnesia in a limestone is this circumstance, and its rendering diluted nitric acid or aqua fortis milky.

From the analysis of Mr. Tennant, it appears that the magnesian limestones contain from

20·3 to 22·5 magnesia.
29·5 to 31·7 lime.
47·2 carbonic acid.
0·8 clay and oxide of iron.

Magnesian limestones are usually colored brown or a pale yellow. They are found in Somersetshire, Leicestershire, Derbyshire, Shropshire, Durham, and Yorkshire. I have never met with any in other counties in England; but they abound in many parts of Ireland, particularly near Belfast.

The use of lime as a cement is not a proper subject for extensive discussion in a course of lectures

---

I have made, I have satisfied myself that it arrests equally vinous and the putrid fermentation, and that in close vessels it may be used for preserving both animal and vegetable substances. When it promotes the solution of vegetable substances, it is probably owing either to forming with them soluble compounds, as in the instance of ulmin, (before mentioned,) or in promoting the production of proximate principles from their elements, capable of entering into union with it, and with which it forms such soluble compounds.—J. D.

on the chemistry of agriculture; yet as the theory of the operation of lime in this way is not fully stated in any elementary book that I have perused, I shall say a very few words on the applications of this part of chemical knowledge.

There are two modes in which lime acts as a cement; in its combination with water, and in its combination with carbonic acid.

The hydrate of lime has been already mentioned. When quicklime is rapidly made into a paste with water, it soon loses its softness, and the water and the lime form together a solid coherent mass, which consists, as has been stated before, of 17 parts of water to 55 parts of lime. When hydrate of lime whilst it is consolidating is mixed with red oxide of iron, alumina, or silica, the mixture becomes harder and more coherent than when lime alone is used; and it appears that this is owing to a certain degree of chemical attraction between hydrate of lime and these bodies; and they render it less liable to decompose by the action of the carbonic acid in the air, and less soluble in water.

The basis of all cements that are used for works which are to be covered with water must be formed from hydrate of lime; and the lime made from impure limestones answers this purpose very well. Puzzolana is composed principally of silica, alumina, and oxide of iron; and it is used mixed with lime, to form cements intended to be employed under water. Mr. Smeaton, in the construction of the Eddystone lighthouse, used a cement composed of equal parts by weight of slacked lime and puzzolana. Puzzolana is a decomposed lava. Tarras, which was formerly imported in considerable quantities from Holland, is a mere decomposed basalt: two parts of slacked lime and one part of tarras form the principal part of the mortar used in the great dikes of Holland. Substances which will answer all the ends of puzzolana and tarras are abundant in the British islands. An excellent red tarras may be procured in any quantities from the Giants' Causeway in the north of Ireland; and decomposing basalt is abundant in many parts of Scotland, and in the northern districts of England in which coal is found.

Parker's cement, and cements of the same kind made at the alum works of Lord Dundas and Lord Mulgrave, are mixtures of calcined ferruginous, siliceous, and aluminous matter, with hydrate of lime.

The cements which act by combining with carbonic acid, or the common mortars, are made by mixing together slacked lime and sand. These mortars at first solidify as hydrates, and are slowly converted into carbonate of lime by the action of the carbonic acid of the air. Mr. Tennant found that a mortar of this kind in three years and a quarter had regained 63 per cent. of the quantity of carbonic acid gas which constitutes the definite proportion in carbonate of lime. The rubbish of mortar from houses owes its power to benefit lands principally to the carbonate of lime it contains, and the sand in it; and its state of cohesion renders it particularly fitted to improve clayey soils.

The hardness of the mortar in very old buildings depends upon the perfect conversion of all its parts into carbonate of lime. The purest limestones are the best adapted for making this kind of mortar; the magnesian limestones make excellent water cements, but act with too little energy upon carbonic acid gas to make good common mortar.

The Romans, according to Pliny, made their best mortar a year before it was used; so that it was partially combined with carbonic acid gas before it was employed.*

In burning lime there are some particular precautions required for the different kinds of limestones. In general, one bushel of coal is sufficient to make four or five bushels of lime. The magnesian limestone requires less fuel than the common limestone. In all cases in which a limestone containing much aluminous or siliceous earth is burnt, great care should be taken to prevent the fire from becoming too intense; for such lime easily vitrifies, in consequence of the affinity of lime for silica and alumina. And as in some places there are no other limestones than such as contain other earths, it is important to attend to this circumstance. A moderately good lime may be made at a low red heat; but it will melt into a glass at a white heat. In lime-kilns for burning such lime, there should be always a damper.

In general, when limestones are not magnesian, their purity will be indicated by their loss of weight in burning; the more they lose, the larger is the quantity of calcareous matter they contain. The magnesian limestones contain more carbonic acid than the common limestones; and I have found all of them lose more than half their weight by calcination.

Besides being used in the forms of lime and carbonate of lime, calcareous matter is applied for the purposes of agriculture in other combinations. One of these bodies is *gypsum* or sulphate of lime. This substance consists of sulphuric acid (the same body that exists combined with water in oil of vitriol) and lime; and when dry it is composed of 55 parts of lime and 75 parts of sulphuric acid. Common gypsum or selenite, such as that found at Shotover Hill near Oxford, contains, besides sulphuric acid and lime, a considerable quantity of water; and its composition may be thus expressed:—

Sulphuric acid, one proportion	-	75
Lime, one proportion - - -	-	55
Water, two proportions -	-	34

The nature of gypsum is easily demonstrated: if oil of vitriol be added to quicklime, there is a violent heat produced; when the mixture is ignited, water is given off, and gypsum alone is the result, if the acid has been used in sufficient quantity; and gypsum mixed with quicklime, if the quantity has been deficient. Gypsum free from water is sometimes found in nature, when it is called anhydrous selenite. It is distinguished from common gypsum by giving off no water when heated.

When gypsum, free from water, or deprived of water by heat, is made into a paste with water, it rapidly sets by combining with that fluid. Plaster of Paris is powdered dry gypsum,† and its property as a cement, and in its use in making casts, depends upon its solidifying a certain quan-

* Pliny, speaking of the qualities of mortars, says, "Intrita quoque quo vetustior eo melior. In antiquarum edium legibus invenitur, ne recentiore trima uteretur redemptor." Nat. Hist. lib. xxxvi. cap. 23.—J. D.

† Anhydrous gypsum.

tity of water, and making with it a coherent mass. Gypsum is soluble in about 500 times its weight of cold water, and is more soluble in hot water; so that when water has been boiled in contact with gypsum, crystals of this substance are deposited as the water cools. Gypsum is easily distinguished when dissolved by its properties of affording precipitates to solutions of oxalates and barytic salts.

Great difference of opinion has prevailed amongst agriculturists with respect to the uses of gypsum. It has been advantageously used in Kent, and various testimonies in favor of its efficacy have been laid before the Board of Agriculture by Mr. Smith. In America it is employed with signal success; but in most counties of England it has failed, though tried in various ways and upon different crops.

Very discordant notions have been formed as to the mode of operation of gypsum. It has been supposed by some persons to act by its power of attracting moisture from the air; but this agency must be comparatively insignificant. When *combined* with water, it retains that fluid too powerfully to yield it to the roots of the plant, and its adhesive attraction for moisture is inconsiderable; the small quantity in which it is used, likewise, is a circumstance hostile to this idea.

It has been said that gypsum assists the putrefaction of animal substances, and the decomposition of manure. I have tried some experiments on this subject, which are contradictory to the notion. I mixed some minced veal with about $\frac{1}{100}$ part of its weight of gypsum, and exposed some veal without gypsum under the same circumstances; there was no difference in the time in which they began to putrefy, and the process seemed to me most rapid in the case in which there was no gypsum present. I made other similar mixtures, employing in some cases larger and in some cases smaller quantities of gypsum; and I used pigeons' dung in one instance instead of flesh, and with precisely similar results. It certainly in no case increased the rapidity of putrefaction.

Though it is not generally known, yet a series of experiments has been carried on for a great length of time in this country upon the operation of gypsum as a manure. The Berkshire and the Wiltshire peat-ashes contain a considerable portion of this substance. In the Newbury peat-ashes I have found from one-fourth to one-third of gypsum; and a larger quantity in some peat-ashes from the neighborhood of Stockbridge: the other constituents of these ashes are calcareous, aluminous, and siliceous earth, with variable quantities of sulphate of potassa, a little common salt, and sometimes oxide of iron. The red ashes contain most of this last substance.

These peat-ashes are used as a top-dressing for cultivated grasses, particularly sainfoin and clover. In examining the ashes of sainfoin, clover, and rye grass, I found that they afforded considerable quantities of gypsum; and this substance, probably, is intimately combined as a necessary part of their woody fibre. If this be allowed, it is easy to explain the reason why it operates in such small quantities; for the whole of a clover crop, or sainfoin crop, on an acre, according to my estimation, would afford by incineration only three or four bushels of gypsum. In examining the soil in a field near Newbury, which was taken from below a footpath near the gate, where gypsum could not have been artificially furnished, I could not detect any of this substance in it; and at the very time I collected the soil, the peat-ashes were applied to the clover in the field. The reason why gypsum is not generally efficacious, is probably because most cultivated soils contain it in sufficient quantities for the use of the grasses. In the common course of cultivation, gypsum is furnished in the manure; for it is contained in stable dung, and in the dung of all cattle fed on grass; and it is not taken up in corn crops, or crops of peas and beans, and in very small quantities in turnip crops; but where lands are exclusively devoted to pasturage and hay, it will be continually consumed. I have examined four different soils, cultivated by a series of common courses of crops, for gypsum. One was a light sand from Norfolk; another a clay, bearing good wheat, from Middlesex; the third a sand from Sussex; the fourth a clay from Essex. I found gypsum in all of them; and in the Middlesex soil it amounted nearly to one per cent. Lord Dundas informs me, that having tried gypsum without any benefit on two of his estates in Yorkshire, he was induced to have the soil examined for gypsum, according to the process described in the fourth lecture, and this substance was found in both the soils.

Should these statements be confirmed by future inquiries, a practical inference of some value may be derived from them. It is possible that lands which have ceased to bear good crops of clover, or artificial grasses, may be restored by being manured with gypsum. I have mentioned that this substance is found in Oxfordshire; it is likewise abundant in many other parts of England; in Gloucestershire, Somersetshire, Derbyshire, Yorkshire, &c.; and requires only pulverisation for its preparation.*

Some very interesting documents upon the use of sulphate of iron or green vitriol, which is a salt produced from peat in Bedfordshire, have been laid before the Board by Dr. Pearson; and I have witnessed the fertilizing effects of a ferruginous water used for irrigating a grass meadow made by the Duke of Manchester, at Priestley Bog, near Woburn, an account of the produce of which has been published by the Board of Agriculture. I have no doubt that the peat salt and the vitriolic water acted chiefly by producing gypsum.

The soils on which both are efficacious are calcareous; and sulphate of iron is decomposed by the carbonate of lime in such soils. The sulphate of iron consists of sulphuric acid and oxide of iron, and is an acid and a very soluble salt: when a solution of it is mixed with carbonate of lime, the sulphuric acid quits the oxide of iron to unite to the lime, and the compounds produced are insipid and comparatively insoluble.

I collected some of the deposition from the ferruginous water on the soil in Priestley meadow. I found it consisted of gypsum, carbonate or iron,

* The manner in which gypsum acts in promoting the vegetation of the grasses, is still a disputed question. M. De Candolle rejects the opinion expressed in the text, and adopts that of M. Soquet, somewhat modified; he thinks that gypsum is not so much useful in the soil, if indeed it is at all, as when scattered on the surface, and that it acts chiefly by stimulating the leaves of the plants to which it adheres. (Vide Physiologie Végétale, p. 1273.—J. D.

and insoluble sulphate of iron. The principal grasses in Priestley meadow are, meadow fox-tail, cock's-foot, meadow fescue, fiorin, and sweet-scented vernal grass. I have examined the ashes of three of these grasses, meadow fox-tail, cock's-foot, and fiorin. They contained a considerable proportion of gypsum.

Vitriolic impregnations, in soils where there is no calcareous matter, as in a soil from Lincolnshire, to which I referred in the fourth lecture, are injurious; but it is probably in consequence of their supplying an excess of ferruginous matter to the sap. Oxide of iron in small quantities forms a useful part of soils; and, as is evident from the details in the third lecture, it is found in the ashes of plants; and probably, is hurtful only in its acid combinations.

I have just mentioned certain peats, the ashes of which afford gypsum; but it must not be inferred from this that all peats agree with them. I have examined various peat-ashes from Scotland, Ireland, Wales, and the northern and western parts of England, which contained no quantity that could be useful; and these ashes abounded in siliceous, aluminous earths, and oxide of iron.

Lord Charleville found in some peat-ashes from Ireland sulphate of potassa, *i. e.* the sulphuric acid combined with potassa.

Vitriolic matter is usually formed in peats; and if the soil or substratum is calcareous, the ultimate result is the production of gypsum. In general, when a recent peat-ash emits a strong smell resembling that of rotten eggs when acted upon by vinegar, it will furnish gypsum.

Phosphate of lime is a combination of phosphoric acid and lime, one proportion of each. It is a compound insoluble in pure water, but soluble in water containing any acid matter. It forms the greatest part of calcined bones. It exists in most excrementitious substances, and is found both in the straw and grain of wheat, barley, oats, and rye, and likewise in beans, peas, and tares. It exists in some places in these islands native; but only in very small quantities. Phosphate of lime is generally conveyed to the land in the composition of other manure; and it is probably necessary to corn crops and other white crops.

Bone-ashes ground to powder will probably be found useful on arable lands containing much vegetable matter, and may perhaps enable soft peats to produce wheat; but the powdered bone in an uncalcined state is much to be preferred in all cases when it can be procured.

The *saline compounds of magnesia* will require very little discussion as to their uses as manures. The most important relations of this subject to agriculture have been considered in the former part of this lecture, when the application of the magnesian limestone was examined. In combination with sulphuric acid magnesia forms a soluble salt. This substance, it is stated by some inquirers, has been found of use as a manure; but it is not found in nature in sufficient abundance, nor is it capable of being made artificially sufficiently cheap to be of useful application in the common course of husbandry.

Wood ashes consist principally of the vegetable alkali united to carbonic acid; and as this alkali is found in almost all plants, it is not difficult to conceive that it may form an essential part of their organs. The general tendency of the alkalies is to give solubility to vegetable matters; and in this way they may render carbonaceous and other substances capable of being taken up by the tubes in the radicle fibres of plants. The vegetable alkali, likewise, has a strong attraction for water, and even in small quantities may tend to give a due degree of moisture to the soil, or to other manures*; though this operation, from the small quantities used, or existing in the soil, can be only of a secondary kind.

The *mineral alkali or soda* is found in the ashes of sea-weed, and may be procured by certain chemical agencies from *common salt.* Common salt consists of the metal named sodium combined with chlorine; and pure soda consists of the same metal united to oxygen. When water is present which can afford oxygen to the sodium, soda may be obtained in several modes from salt.

The same reasoning will apply to the operation of the pure mineral alkali, or the carbonated alkali, as to that of the vegetable alkali; and when common salt acts as a manure, it is probably by entering into the composition of the plant in the same manner as gypsum, phosphate of lime, and the alkalies. Sir John Pringle has stated that salt in small quantities assists the decomposition of animal and vegetable matter. This circumstance may render it useful in certain soils. Common salt likewise is offensive to insects. That in small quantities it is sometimes a useful manure, I believe is fully proved; and it is probable that its efficacy depends upon many combined causes.

Some persons have argued against the employment of salt; because, when used in large quantities, it either does no good, or renders the ground steril; but this is a very unfair mode of reasoning. That salt in large quantities rendered land barren, was known long before any records of agricultural science existed. We read in the Scriptures, that Abimelech took the city of Shechem, "and beat down the city, and sowed it with salt," that the soil might be for ever unfruitful. Virgil reprobates a salt soil; and Pliny, though he recommends giving salt to cattle, yet affirms that when strewed over land it renders it barren. But these are not arguments against a proper application of it. Refuse salt in Cornwall, which, however, likewise contains some of the oil and exuviæ of fish, has long been known as an admirable manure. And the Cheshire farmers contend for the benefit of the peculiar produce of their country. It is not unlikely that the same causes influence the effects of salt as those which act in modifying the operation of gypsum. Most lands in this island, particularly those near the sea, probably contain a sufficient quantity of salt for all the purposes of vegetation; and in such cases the supply of it to the soil will not only be useless, but may be injurious. In great storms the spray of the sea has been carried more than 50 miles from the shore; so that from this source salt must be often supplied to the soil. I have found salt in all the sandstone rocks that I have examined, and it must

* This effect is well illustrated by the dampness of walls and floors impregnated with minute quantities of deliquescent salts, such as exist in sea-water. In further illustration, I may mention a striking instance of dampness, amounting to a constant dropping of water, from the ceiling of an uninhabited room impregnated with salt, from brine having been spilt on the floor of the room above some years previously.—J. D

exist in the soil derived from these rocks. It is a constituent, likewise, of almost every kind of animal and vegetable manure.

Besides these compounds of the alkaline earths and alkalies, many others have been recommended for the purpose of increasing vegetation; such as *nitre*, or the nitrous acid combined with potassa. Sir Kenelm Digby states, that he made barley grow very luxuriantly by watering it with a very weak solution of nitre; but he is too speculative a writer to awaken confidence in his results. This substance consists of one proportion of azote, six of oxygen, and one of potassium; and it is not unlikely that it may furnish azote to form albumen or gluten in those plants that contain them; but the nitrous salts are too valuable for other purposes to be used as manures.

Dr. Home states that *sulphate of potassa*, which as I just now mentioned is found in the ashes of some peats, is a useful manure. But Mr. Naismith* questions his results; and quotes experiments hostile to his opinion, and, as he conceives, unfavorable to the efficacy of any species of saline manure.

Much of the discordance of the evidence relating to the efficacy of saline substances depends upon the circumstance of their having been used in different proportions, and in general in quantities much too large.

I made a number of experiments in May and June, 1807, on the effects of different saline substances on barley and on grass growing in the same garden, the soil of which was a light sand, of which 100 parts were composed of 60 parts of siliceous sand, and 24 parts finely divided matter, consisting of 7 parts carbonate of lime, 12 parts alumina and silica, less than one part saline matter, principally common salt, with a trace of gypsum and sulphate of magnesia: the remaining 16 parts were vegetable matter.

The solutions of the saline substances were used twice a week in the quantity of two ounces, on spots of grass and corn, sufficiently remote from each other to prevent any interference of results. The substances tried were *super-carbonate, sulphate, acetate, nitrate* and *muriate of potassa; sulphate of soda, sulphate, nitrate, muriate*, and *carbonate of ammonia*. I found that in all cases when the quantity of the salt equalled $\frac{1}{30}$ part of the weight of the water, the effects were injurious; but least so in the instances of the carbonate, sulphate, and muriate of ammonia. When the quantities of the salts where $\frac{1}{300}$ part of the solution, the effects were different. The plants watered with the solutions of the sulphates grew just in the same manner as similar plants watered with rain water. Those acted on by the solution of nitre, acetate, and supercarbonate of potassa, and muriate of ammonia, grew rather better.—Those treated with the solution of carbonate of ammonia grew most luxuriantly of all. This last result is what might be expected, for carbonate of ammonia consists of carbon, hydrogen, azote, and oxygen. There was, however, another result which I had not anticipated; the plants watered with solution of nitrate of ammonia did not grow better than those watered with rain water. The solution reddened litmus paper; and probably the free acid exerted a prejudicial effect, and interfered with the result.

Soot doubtless owes a part of its efficacy to the ammoniacal salt it contains. The liquor produced by the distillation of coal contains carbonate and acetate of ammonia, and is said to be a very good manure.

In 1808, I found the growth of wheat in a field at Roehampton assisted by a very weak solution of acetate of ammonia.

Soapers' waste has been recommended as a manure, and it has been supposed that its efficacy depended upon the different saline matters it contains; but their quantity is very minute, indeed, and its principal ingredients are mild lime and quicklime. In the soapers' waste from the best manufactories, there is scarcely a trace of alkali. Lime moistened with sea-water affords more of this substance, and is said to have been used in some cases with more benefit than common lime.

Mr. Knight informs me, that he has found, in the two last seasons, that pond mud, of very poor quality, chiefly clay, having been mixed with coal dust, to afford fuel for his hot-houses, afforded a manure of considerable power. It acts, however, much more beneficially upon soils which are in tolerably good condition, and perhaps rather stimulates than feeds; for on very poor soil, where some was laid in the last winter, its effects can scarcely be perceived.

It is unnecessary to discuss to any greater extent the effects of saline substances on vegetation; except the ammoniacal compounds, or the compounds containing nitric, acetic, and carbonic acid, none of them can afford by their decomposition any of the common principles of vegetation, carbon, hydrogen, and oxygen.

The alkaline sulphates and the earthy muriates are so seldom found in plants, or are found in such minute quantities, that it can never be an object to apply them to the soil. It was stated in the beginning of this lecture, that the earthy and alkaline substances seem never to be formed in vegetation; and there is every reason likewise to believe that they are never decomposed; for after being absorbed they are found in their ashes.

The metallic bases of them cannot exist in contact with aqueous fluids; and these metallic bases, like other metals, have not as yet been resolved into any other forms of matter by artificial processes; they combine readily with other elements; but they remain undestructible, and can be traced undiminished in quantity, through their diversified combinations.

LECTURE VIII.

ON THE IMPROVEMENT OF LANDS BY BURNING; CHEMICAL PRINCIPLES OF THIS OPERATION. ON IRRIGATION AND ITS EFFECTS. ON FALLOWING; ITS DISADVANTAGES AND USES. ON THE CONVERTIBLE HUSBANDRY FOUNDED ON REGULAR ROTATIONS ON DIFFERENT CROPS. ON PASTURE; VIEWS CONNECTED WITH ITS APPLICATION. ON VARIOUS AGRICULTURAL OBJECTS CONNECTED WITH CHEMISTRY. CONCLUSION.

The improvement of steril lands by burning was known to the Romans. It is mentioned by

* Elements of Agriculture, p. 78.

Virgil in the first book of the Georgics: "Sæpe etiam steriles incendere profuit agros." It is a practice still much in use in many parts of these islands; the theory of its operation has occasioned much discussion, both among scientific men and farmers. It rests entirely upon chemical doctrines; and I trust I shall be able to offer you satisfactory elucidations on the subject.

The bases of all common soils, as I stated in the fourth lecture, are mixtures of the primitive earths and oxide of iron; and these earths have a certain degree of attraction for each other. To regard this attraction in its proper point of view, it is only necessary to consider the composition of any common siliceous stone. Feldspar, for instance, contains siliceous, aluminous, calcareous earths, fixed alkali, and oxide of iron, which exist in one compound, in consequence of their chemical attractions for each other. Let this stone be ground into impalpable powder, it then becomes a substance like clay: if the powder be heated very strongly it fuses, and on cooling forms a coherent mass similar to the original stone; the parts separated by mechanical division adhere again in consequence of chemical attraction. If the powder is heated less strongly, the particles only superficially combine with each other, and form a gritty mass, which, when broken into pieces, has the characters of sand.

If the power of the powdered feldspar to absorb water from the atmosphere, before and after the application of the heat, be compared, it is found much less in the last case.

The same effect takes place when the powder of other siliceous or aluminous stones is made the subject of experiment.

I found that two equal portions of basalt ground into impalpable powder, of which one had been strongly ignited, and the other exposed only to a temperature equal to that of boiling water, gained very different weights in the same time when exposed to air. In four hours the one had gained only two grains, whilst the other had gained seven grains.

When clay or tenacious soils are burnt, the effect is of the same kind; they are brought nearer to a state analogous to that of sands.

In the manufacture of bricks the general principle is well illustrated; if a piece of dry brick earth be applied to the tongue, it will adhere to it very strongly, in consequence of its power to absorb water; but after it has been burnt there will be scarcely a sensible adhesion.*

The process of burning renders the soil less compact, less tenacious and retentive of moisture; and when properly applied, may convert a matter that was stiff, damp, and in consequence cold, into one powdery, dry, and warm; and much more proper as a bed for vegetable life.

The great objection made by speculative chemists to paring and burning is, that it destroys vegetable and animal matter, or the manure in the soil; but in cases in which the texture of its earthy ingredients is permanently improved, there is more than a compensation for this temporary disadvantage. And in some soils where there is an excess of inert vegetable matter, the destruction of it must be beneficial: and the carbonaceous matter remaining in the ashes may be more useful to the crop than the vegetable fibre from which it was produced.

I have examined by a chemical analysis three specimens of ashes, from different lands that had undergone paring and burning. The first was a quantity sent to the board by Mr. Boys of Bellhanger, in Kent, whose treatise on paring and burning has been published. They were from a chalk soil, and 200 grains contained

80 Carbonate of lime.
11 Gypsum.
9 Charcoal.
15 Oxide of iron.
3 Saline matter; viz. sulphate of potash, muriate of magnesia, with a minute quantity of vegetable alkali.

The remainder alumina and silica.

Mr. Boys estimates that 2660 bushels are the common produce of an acre of ground, which, according to his calculation, would give 172900 lbs. containing

Carbonate of lime -	69160 *lbs.*
Gypsum - -	9509·5
Oxide of iron -	12967·5
Saline matter -	2593·5
Charcoal - -	7780·5

In this instance there was undoubtedly a very considerable quantity of matter capable of being active as manure produced in the operation of burning. The charcoal was very finely divided; and, exposed on a large surface on the field, must have been gradually converted into carbonic acid. And gypsum and oxide of iron, as I mentioned in the last lecture, seem to produce the very best effects when applied to lands containing an excess of carbonate of lime.

The second specimen was from a soil near Coleorton, in Leicestershire, containing only four per cent. of carbonate of lime, and consisting of three-fourths light siliceous sand, and about one-fourth clay. This had been turf before burning, and 100 parts of the ashes gave

6 Parts charcoal.
3 Muriate of soda and sulphate of potash, with a trace of vegetable alkali.
9 Oxide of iron.

And the remainder the earths.

In this instance, as in the other, finely divided charcoal was found; the solubility of which would be increased by the presence of the alkali.

The third instance was that of a stiff clay, from Mount's Bay, Cornwall. This land had been brought into cultivation from a heath by burning about ten years before; but having been neglected, furze was springing up in different parts of it, which gave rise to the second paring and burning: 100 parts of the ashes contained

8 Parts of charcoal.
2 Of saline matter, principally common salt, with a little vegetable alkali.
7 Oxide of iron.
2 Carbonate of lime.

Remainder alumina and silica.

Here the quantity of charcoal was greater than in the other instances. The salt, I suspect, was owing to the vicinity of the sea, it being but two miles off. In this land there was certainly an excess of dead vegetable fibre, as well as unprofita-

* Clay has the remarkable property of confining water; and therefore a thin layer of clay may have a very injurious effect, by preventing rain water from penetrating deeply and saturating the subsoil; an evil which may be corrected by paring and burning.—J. D.

ble living vegetable matter; and I have since heard that a great improvement took place.

Many obscure causes have been referred to for the purpose of explaining the effects of paring and burning; but I believe they may be referred entirely to the diminution of the coherence and tenacity of clays, and to the destruction of inert and useless vegetable matter, and its conversion into a manure.

Dr. Darwin, in his Phytologia, has supposed that clay during torrefaction may absorb some nutritive principles from the atmosphere that afterwards may be supplied to plants; but the earths are pure metallic oxides, saturated with oxygen; and the tendency of burning is to expel any other volatile principles that they may contain in combination. If the oxide of iron in soils is not saturated with oxygen, torrefaction tends to produce its further union with this principle; and hence in burning the color of clays changes to red. The oxide of iron containing its full proportion of oxygen has less attraction for acids than the other oxide, and is consequently less likely to be dissolved by any fluid acid in the soil; and it appears in this state to act in the same manner as the earths. A very ingenious author, whom I quoted at the end of the last lecture, supposes that the oxide of iron when combined with carbonic acid is poisonous to plants, and that one use of torrefaction is to expel the carbonic acid from it; but the carbonate of iron is not soluble in water, and is a very inert substance; and I have raised a luxuriant crop of cresses in a soil composed of one-fifth carbonate of iron, and four-fifths carbonate of lime. Carbonate of iron abounds in some of the most fertile soils in England, particularly the red hop soil. And there is no theoretical ground for supposing that carbonic acid, which is an essential food of plants, should in any of its combinations be poisonous to them; and it is known that lime and magnesia are both noxious to vegetation unless combined with this principle.

All soils that contain too much dead vegetable fibre, and which consequently lose from one-third to one-half of their weight by incineration, and all such as contain their earthy constituents in an impalpable state of division, *i. e.* the stiff clays and marls, are improved by burning; but in coarse sands, or rich soils containing a just mixture of the earths, and in all cases in which the texture is already sufficiently loose, or the organisable matter sufficiently soluble, the process of torrefaction cannot be useful.

All poor siliceous sands must be injured by it; and here practice is found to accord with theory. Mr. Young, in his Essay on Manures, states, "that he found burning injure sand;" and the operation is never performed by good agriculturists upon siliceous sandy soils, after they have once been brought into cultivation.

An intelligent farmer in Mount's Bay told me that he had pared and burned a small field several years ago, which he had not been able to bring again into good condition. I examined the spot; the grass was very poor and scanty, and the soil an arid siliceous sand.

Irrigation, or *watering land*, is a practice which, at first view, appears the reverse of torrefaction; and in general, in nature, the operation of water is to bring earthy substances into an extreme state of division. But in the artificial watering of meadows, the beneficial effects depend upon many different causes,—some chemical, some mechanical.

Water is absolutely essential to vegetation; and when land has been covered by water in the winter, or in the beginning of spring, the moisture that has penetrated deep into the soil, and even the sub-soil, becomes a source of nourishment to the roots of the plant in the summer, and prevents those bad effects that often happen in lands in their natural state, from a long continuance of dry weather.

When the water used in irrigation has flowed over a calcareous country, it is generally found impregnated with carbonate of lime; and in this state it tends, in many instances, to ameliorate the soil.*

Common river-water, also, generally contains a certain portion of organisable matter, which is much greater after rains than at other times; and which exists in the largest quantity when the stream rises in a cultivated country.

Even in cases when the water used for flooding is pure, and free from animal or vegetable substances, it acts by causing the more equable diffusion of nutritive matter existing in the land; and in very cold seasons it preserves the tender roots and leaves of the grass from being affected by frost.

Water is of greater specific gravity at 42° Fahrenheit, than at 32°; the freezing point; and hence in a meadow irrigated in winter, the water immediately in contact with the grass is rarely below 40°, a degree of temperature not at all prejudicial to the living organs of plants.

In 1804, in the month of March, I examined the temperature in a water meadow near Hungerford, in Berkshire, by a very delicate thermometer. The temperature of the air at seven in the morning was 29°. The water was frozen above the grass. The temperature of the soil below the water in which the roots of the grass were fixed was 43°.

In general those waters which breed the best fish are the best fitted for watering meadows; but most of the benefits of irrigation may be derived from any kind of water. It is, however, a general principle, that waters containing ferruginous impregnations, though possessed of fertilizing effects, when applied to a calcareous soil, are injurious on soils that do not effervesce with acids; and that calcareous waters, which are known by the earthy deposite they afford when boiled, are of most use on siliceous soils, or other soils containing no remarkable quantity of carbonate of lime.

The most important processes for improving land are those which have been already discussed, and that are founded upon the circumstance of removing certain constituents from the soil, or adding others, or changing their nature; but there is an operation of very ancient practice still much

* And, I may add, to counteract the effect of rain-water, to dissolve and remove carbonate of lime from the soil. In Malta, where irrigation is much employed, the water containing carbonate of lime, I have found no deficiency of this compound in the soil of the irrigated lands; but in this country, even in chalk districts, the superficial soil is often entirely destitute of carbonate of lime; it has been removed in process of time, supposing that it previously existed in the soil, by the solvent power of rain-water.—J. D.

employed, in which the soil is exposed to the air, and submitted to processes which are purely mechanical, namely, *fallowing*.

The benefits arising from fallows have been much overrated. A summer fallow, or a clean fallow, may be sometimes necessary in lands overgrown with weeds, particularly if they are sands which cannot be pared and burnt with advantage; but is certainly unprofitable as part of a general system in husbandry.

It has been supposed by some writers, that certain principles necessary to fertility are derived from the atmosphere, which are exhausted by a succession of crops, and that these are again supplied during the repose of the land, and the exposure of the pulverized soil to the influence of the air; but this, as was mentioned in the introductory lecture, is not a correct statement. Oxygen is absorbed by the vegetable film, and, perhaps, in certain cases, azote; but the earths, the great elements of soils, cannot be combined with new elements from the air; none of them unite to azote; and such of them as are capable of attracting carbonic acid, are always saturated with it in those soils on which the practice of fallowing is adopted. The vague ancient opinion of the use of nitre and of nitrous salts in vegetation, seems to have been one of the principal speculative reasons for the defence of summer fallows. Nitrous salts are produced during the exposure of soils containing vegetable and animal remains, and in greatest abundance in hot weather;* but it is probably by the combination of azote from these remains with oxygen in the atmosphere that the acid is formed, and at the expense of an element which otherwise would have formed ammonia; the compounds of which, as is evident from what is stated in the last lecture, are much more efficacious than the nitrous compounds in assisting vegetation.

When weeds are buried in the soil, by their absorption of oxygen and gradual decomposition they furnish a certain quantity of soluble matter, and a soil will certainly in consequence produce better crops at the end of a fallow; but the use of this practice must depend upon the quantity of vegetable fibre and its nature, and upon the quality of the soil. Carbonic acid gas is formed during the whole time by the action of the vegetable matter upon the oxygen of the air, and the greater part of it is lost to the soil in which it was formed, and dissipated in the atmosphere.

The action of the sun upon the surface of the soil tends to disengage the gaseous and the volatile fluid matters that it contains; and heat increases the rapidity of fermentation: and in the summer fallow, nourishment is rapidly produced, at a time when no vegetables are present capable of absorbing it.

Land, when it is not employed in preparing food for animals, should be applied to the purpose of the preparation of manure for plants; and this is effected by means of green crops, in consequence of the absorption of carbonaceous matter in the carbonic acid of the atmosphere. In a summer's fallow a period is always lost in which vegetables may be raised, either as food for animals, or as nourishment for the next crop; and the texture of the soil is not so much improved by it exposure as in winter, when the expansive powers of ice, the gradual dissolution of snows, and the alternations from wet to dry, tend to pulverize it, and to mix its different parts together.

In the drill husbandry the land is preserved clean by the extirpation of the weeds by hand, by raising the crops in rows, which renders the destruction of the weeds much more easy. Manure is supplied either by the green crops themselves, or from the dung of the cattle fed upon them; and the plants having large systems of leaves are made to alternate with those bearing grain.

It is a great advantage in the convertible system of cultivation, that the whole of the manure is employed; and that those parts of it which are not fitted for one crop remain as nourishment for another. Thus, in Mr. Coke's course of crops, the turnip is the first in the order of succession; and this crop is manured with recent dung, which immediately affords sufficient soluble matter for its nourishment; and the heat produced in fermentation assists the germination of the seed and the growth of the plant. After turnips, barley with grass seeds is sown; and the land, having been little exhausted by the turnip crop, affords the soluble parts of the decomposing manure to the grain. The grasses, rye-grass, and clover remain, which derive a small part only of their organized matter from the soil, and probably consume the gypsum in the manure, which would be useless to other crops: these plants, likewise, by their large systems of leaves, absorb a considerable quantity of nourishment from the atmosphere; and when ploughed in at the end of two years, the decay of their roots and leaves affords manure for the wheat crop: and at this period of the course, the woody fibre of the farm-yard manure, which contains the phosphate of lime and the other difficultly soluble parts, is broken down; and as soon as the most exhausting crop is taken, recent manure is again applied.

Mr. Gregg, whose ingenious system of cultivation has been published by the Board of Agriculture, and who has the merit of first adopting a plan similar to Mr. Coke's upon strong clays, suffers the ground after barley to remain at rest for two years in grass: sows peas and beans on the leys; ploughs in the pea or bean stubble for wheat; and in some instances follows his wheat crops by a course of winter tares and winter barley, which is eat off in the spring, before the land is sowed for turnips.

Peas and beans, in all instances, seem well adapted to prepare the ground for wheat; and in some rich lands, as in the alluvial soil of the Parret, mentioned in the fourth lecture, and at the foot of the South Downs in Sussex, they are raised in alternate crops for years together. Peas and beans contain, as appears from the analyses in the third lecture, a small quantity of matter analogous to albumen; but it seems that the azote, which forms a constituent part of this matter, is derived from the atmosphere. The dry bean leaf, when burnt, yields a smell approaching to that of decomposing animal matter; and in its decay in the

* Nitre and nitrate of lime are the two nitrous salts of most common occurrence; the presence of lime appears to be essential to the production of both. In situations, however favorable in other respects, in which there is no potash pre-existing, there nitre will not form; nitrate of lime will appear alone. Nitre, therefore, is chiefly confined to countries of primary rock formations, containing feldspar or some analogous mineral, which in decomposing yields potassa.—J. D.

soil, may furnish principles capable of becoming a part of the gluten in wheat.

In considering what vegetables are likely to be profitable on a particular *soil*, it is necessary always to attend, not only to the mean temperature of the climate, but likewise to the summer's heat and winter's cold. Thus, maize, or Indian corn, and the vine, require a very hot summer; and the olive would be destroyed by our winter. It is unnecessary, therefore, to say any thing of these plants, or similar plants, in relation to a British system of cultivation: but, in some of our colonies, particularly the Cape of Good Hope, almost all the vegetable productions of Italy, Portugal, or Spain, are or may be raised. The wines of the Cape may be doubtless improved by a proper selection of soils, and by employing peasants from the vine countries of France in cultivating the grape, and in the manufacture of wine. The flavor of the juice of the grape changes as the soil is different; and in selecting a place for a vineyard, much may be gained by analyses or chemical examination of the soil, and by comparing it with the best soils of the best wine provinces of France, Germany, and Spain. This is a subject not unworthy the attention of our government.

Though the general composition of plants is very analogous, yet the specific difference in the products of many of them, and the facts stated in the last lecture, prove that they must derive different materials from the soil; and though the vegetables having the smallest systems of leaves will proportionably most exhaust the soil of common nutritive matter, yet particular vegetables, when their produce is carried off, will require peculiar principles to be supplied to the land in which they grow. Strawberries and potatoes at first produce luxuriantly in virgin mould recently turned up from pasture; but in a few years they degenerate, and require fresh soil; and the organisation of these plants is such, as to be constantly producing the migration of their layers: thus the strawberry by its long shoots is constantly endeavoring to occupy a new soil; and the fibrous radicles of the potato produce bulbs at a considerable distance from the parent plant. Lands in a course of years often cease to afford good cultivated grasses; they become (as it is popularly said) tired of them; and one of the probable reasons for this was stated in the last lecture.

The most remarkable instance of the powers of vegetables to exhaust the soil of certain principles necessary to their growth, is found in certain funguses. Mushrooms are said never to rise in two successive seasons on the same spot, and the production of the phenomena called fairy wings has been ascribed by Dr. Wollaston to the power of the peculiar fungus which forms it to exhaust the soil of the nutriment necessary for the growth of the species. The consequence is, that the ring annually extends, for no seeds will grow where their parents grew before them, and the interior part of the circle has been exhausted by preceding crops; but where the fungus has died, nourishment is supplied for grass, which usually rises within the circle, coarse, and of a dark green color.*

When cattle are fed upon land not benefited by their manure, the effect is always an exhaustion of the soil; this is particularly the case where carrying horses are kept on estates; they consume the pasture during the night, and drop the greatest part of their manure during their labor in the day-time.

The exportation of grain from a country, unless some articles capable of becoming manure are introduced in compensation, must ultimately tend to exhaust the soil. Some of the spots now desert sands in northern Africa, and Asia Minor, were anciently fertile. Sicily was the granary of Italy; and the quantity of corn carried off from it by the Romans is probably a chief cause of its present sterility.* In this island, our commercial system at present has the effect of affording substances, which in their use and decomposition must enrich the land. Corn, sugar, tallow, oil, skins, furs, wine, silk, cotton, &c., are imported, and fish are supplied from the sea. Amongst our numerous exports, woollen, and linen, and leather goods are almost the only substances which contain any nutritive materials derived from the soil.

In all courses of crops it is necessary that every part of the soil should be made as useful as possible to the different plants; but the depth of the furrow in ploughing must depend upon the nature of the soil, and of the subsoil. In rich clayey soils the furrow can scarcely be too deep; and even in sands, unless the subsoil contains some principles noxious to vegetables, the same practice should be adopted. When the roots are deep, they are less liable to be injured, either by excess of rain, or drought; the layers shoot forth their radicles into every part of the soil; and the space from which the nourishment is derived is more considerable, than when the seed is superficially inserted in the soil.

There has been much difference of opinion with respect to permanent pasture; but the advantages or disadvantages can only be reasoned upon according to the circumstances of situation and climate. Under the circumstances of irrigation, lands are extremely productive, with comparatively little labor; and in climates where great quantites of rain fall, the natural irrigation produces the same effects as artificial. When hay is in great demand, as sometimes happens in the neighborhood of the metropolis, where manure

* Some effects attributed to exhaustion of soil may be owing to excretions from the roots, injurious to the plants which have yielded them, and yet beneficial to other kinds of plants: in one instance acting the part of a poison, in the other of a manure. *Vide* Physiologie Végétale, pp. 248 and 1474, for some curious information on this important subject, the investigation of which is only just begun.—J. D.

* Sicily is still abundant in corn, and produces more than is sufficient for the use of its inhabitants. If its fertility is diminished, which there is reason to believe is the case, since the best times of the Romans, it may be referred to a bad system of agriculture, connected with an oppressive government. The corn-lands of the adjoining little island of Malta, well cultivated, are wonderfully fertile, yielding often a return of fifteen fold of wheat, and sometimes of thirty-two fold of barley; whilst in the Ionian Islands, especially at Cerigo, where the soil is similar, but where manure is not used, and the same land is yearly under the plough, the produce of wheat seldom exceeds five fold; and in all these islands, from time immemorial, corn has been imported, the most fertile of them not yielding sufficient for six months' consumption.—J. D.

can be easily procured, the application of it to pasture is repaid by the increase of crop; but top-dressing grass land with animal or vegetable manure cannot be recommended as a general system. Dr. Coventry very justly observes, that there is a greater waste of the manure in this case than when it is ploughed into the soil for seed crops. The loss by exposure to the air and the sunshine offers reasons, in addition to those that have been already quoted in the sixth lecture, for the application of manure, even in this case, in a state of incipient and not completed fermentation.

Very little attention has been paid to the nature of the grasses best adapted for permanent pasture. The chief circumstance which gives value to a grass is the quantity of nutritive matter that the whole crop will afford; but the time and duration of its produce are likewise points of great importance; and a grass that supplies green nutriment throughout the whole of the year may be more valuable than a grass which yields its produce only in summer, though the whole quantity of food supplied by it should be much less.

The grasses that propagate themselves by layers, the different species of agrostis, supply pasture throughout the year; and, as it has been mentioned on a former occasion, the concrete sap stored up in their joints renders them a good food even in winter. I saw four square yards of fiorin grass cut in the end of January, this year, in a meadow exclusively appropriated to the cultivation of fiorin, by the Countess of Hardwicke, the soil of which is a damp stiff clay. They afforded 28 pounds of fodder; of which 1000 parts afforded 64 parts of nutritive matter, consisting nearly of one-sixth of sugar, and five-sixths of mucilage, with a little extractive matter. In another experiment, four square yards gave 27 pounds of grass. The quality of this grass is inferior to that of the fiorin referred to in the table, in the latter part of the third lecture, which was cultivated by Sir Joseph Banks in Middlesex, in a much richer soil, and cut in December.

The fiorin grass, to be in perfection, requires a moist climate or a wet soil; and it grows luxuriantly in cold clays unfitted for other grasses. In light sands and in dry situations its produce is much inferior as to quantity and quality.

The common grasses, properly so called, that afford most nutritive matter in early spring, are the vernal meadow grass and meadow fox-tail grass; but their produce, at the time of flowering and ripening the seed, is inferior to that of a great number of other grasses; their latter-math is, however, abundant.

Tall fescue grass stands highest, according to the experiments of the Duke of Bedford, of any grass properly so called, as to the quantity of nutritive matter afforded by the whole crop when cut at the time of flowering; and meadow cat's-tail grass affords most food when cut at the time the seed is ripe: the highest latter-math produce of the grasses examined in the Duke of Bedford's experiments is from the sea-meadow grass.

Nature has provided in all permanent pastures a mixture of various grasses, the produce of which differs at different seasons. Where pastures are to be made artificially, such a mixture ought to be imitated; and, perhaps, pastures superior to the natural ones may be made by selecting due proportions of those species of grasses fitted for the soil which afford respectively the greatest quantities of spring, summer, latter-math, and winter produce. A reference to the details in the appendix will show that such a plan of cultivation is very practicable.

The propagation of grasses by layers has lately given rise to a considerable improvement in the formation of pasture, by what has been called inocculation. A certain portion of old pasture is removed with the roots of the grasses and a part of the soil, and planted (as it were) in arable land at certain intervals. By the spreading of the layers, a surface of grasses is speedily formed; and the old pasture, if too much of it be not removed, soon recovers itself, in consequence of the operation of the same principle. This improvement has arisen in the same place where agriculture has so long been an object of unremitted and patriotic exertions. Mr. Coke's steward is the author.

In all lands, whether arable or pasture, weeds, of every description, should be rooted out before the seed is ripe; and if they are suffered to remain in hedge-rows, they should be cut when in flower, or before, and made into heaps for manure: in this case they will furnish more nutritive matter in their decomposition; and their increase by the dispersion of seeds will be prevented. The farmer, who suffers weeds to remain till their ripe seeds are shed, and scattered by the winds, is not only hostile to his own interests, but is likewise an enemy to the public: a few thistles neglected soon will stock a farm; and by the light down which is attached to their seeds, they may be distributed over a whole country. Nature has provided such ample resources for the continuance of even the meanest vegetable tribes, that it is very difficult to ensure the destruction of such as are hostile to the agriculturist, even with every precaution. Seeds excluded from the air will remain for years inactive in the soil*, and yet germinate under favorable circumstances; and the different plants, the seeds of which, like those of the thistle and dandelion, are furnished with beards or wings, may be brought from an immense distance. The flea-bane of Canada has only lately been found in Europe; and Linnæus supposes that it has been transported from America, by the very light downy plumes with which the seed is provided.

In feeding cattle with green food, there are many advantages in *soiling*, or supplying them with food, where their manure is preserved, out of the field: the plants are less injured when cut than when torn or jagged by the teeth of the cattle, and no food is wasted by being trodden down. They are likewise obliged to feed without making a selection; and in consequence the whole food is con-

*The appearance of seeds in places where their parent plants are not found may be easily accounted for from this circumstance, and other circumstances. Many seeds are carried from island to island by currents in the sea, and are defended by their hard coats from the immediate action of the water. West Indian seeds (of this description) are often found on our coasts, and readily germinate; their long voyage having been barely sufficient to afford the cotyledon its due proportion of moisture. Other seeds are carried indigested in the stomach of birds, and supplied with food at the moment of their deposition. The light seeds of the mosses and lichens probably float in every part of the atmosphere, and abound on the surface of the sea.

sumed: the attachment or dislike to a particular kind of food exhibited by animals, offers no proof of its nutritive powers. Cattle, at first, refuse linseed cake, one of the most nutritive substances on which they can be fed.*

When food artificially composed is to be given to cattle, it should be brought as nearly as possi-

---

* For the following observations on the selection of different kinds of common food by sheep and cattle, I am obliged to Mr. George Sinclair.

"*Lolium perenne*, rye-grass. Sheep eat this grass when it is in the early stage of its growth, in preference to most others; but after the seed approaches towards perfection, they leave it for almost any other kind. A field in the park at Woburn was laid down in two equal parts; one part with rye-grass and white clover, and the other part with cock's-foot and red clover: from the spring till midsummer the sheep kept almost constantly on the rye-grass; but after that time they left it, and adhered with equal constancy to the cock's-foot during the remainder of the season.

"*Dactylis glomerata*, cock's-foot. Oxen, horses, and sheep eat this grass readily. The oxen continue to eat the straws and flowers, from the time of flowering till the time of perfecting the seed: this was exemplified in a striking manner in the field before alluded to. The oxen generally kept to the cock's-foot and red clover, and the sheep to the rye-grass and white clover. In the experiments published in the Amœnitates Academicæ, by the pupils of Linnæus, it is asserted that this grass is rejected by oxen: the above fact, however, is in contradiction of it.

"*Alopecurus pratensis*, meadow fox-tail. Sheep and horses seem to have a greater relish for this grass than oxen. It delights in a soil of intermediate quality as to moisture or dryness, and is very productive. In the water-meadow at Priestley, it constitutes a considerable part of the produce of that excellent meadow. It there keeps invariably possession of the top of the ridges, extending generally about six feet from each side of the water-course; the space below that to where the ridge ends is stocked with cock's-foot, the rough-stalked meadow grass, *Festuca pratensis*, *Festuca duriuscula*, *Agrostis stolonifera*, *Agrostis palustris*, and sweet-scented vernal grass, with a small admixture of some other kinds.

"*Phleum pratense*, meadow cat's-tail. This grass is eaten without reserve by oxen, sheep, and horses. Dr. Pulteney says that it is disliked by sheep; but in pastures where it abounds, it does not appear to be rejected by these animals, but eaten in common with such others as are growing with it. Hares are remarkably fond of it. The *Phleum nodosum*, *Phleum alpinum*, *Poa fertilis* and *Poa compressa*, were left untouched, although they were closely adjoining to it. It seems to attain the greatest perfection in a rich deep loam.

"*Agrostis stolonifera*, fiorin. In the experiments detailed in the Amœnitates Academicæ, it is said that horses, sheep, and oxen eat this grass readily. On the Duke of Bedford's farm at Maulden, fiorin hay was placed in the racks before horses in small distinct quantities, alternately with common hay; but no decided preference for either was manifested by the horses in this trial. But that cows and horses prefer it to hay, when in a green state, seems fully proved by Dr. Richardson, in his several publications on fiorin; and of its productive powers in England (which have been doubted by some,) there are satisfactory proofs. Lady Hardwicke has given an account of a trial of this grass; wherein twenty-three milch cows and one young horse, besides a number of pigs, were kept a fortnight on the produce of one acre.

"*Poa trivialis*, rough-stalked meadow. Oxen, horses, and sheep eat this grass with avidity. Hares also eat it; but they give a decided preference to the smooth-stalked meadow grass, to which it is, in many respects, nearly allied.

"*Poa pratensis*, smooth-stalked meadow-grass. Oxen and horses are observed to eat this grass in common with others; but sheep rather prefer the hard fescue, and sheep's fescue, which affect a similar soil. This species exhausts the soil in a greater degree than almost any other species of grass; the roots being numerous, and powerfully creeping, become in two or three years completely matted together; the produce diminishes as this takes place. It grows common in some meadows, dry banks, and even on walls.

"*Cynosurus cristatus*, crested dog's-tail grass. The South Down sheep and deer appear to be remarkably fond of this grass: in some parts of Woburn Park this grass forms the principal part of the herbage on which these animals chiefly browse; while another part of the park, that contains the *Agrostis capillaris*, *Agrostis pumilis*, *Festuca ovina*, *Festuca duriuscula*, and *Festuca cambrica*, is seldom touched by them: but the Welsh breed of sheep almost constantly browse upon these, and neglect the *Cynosurus cristatus*, *Lolium perenne*, and *Poa trivialis*.

"*Agrostis vulgaris* (*capillaris*, Linn.), fine bent; common bent. This is a very common grass on all poor dry sandy soils. It is not palatable to cattle, as they never eat it readily, if any other kinds be within their reach. The Welsh sheep, however, prefer it, as I before observed; and it is singular that those sheep being bred in the park, when some of the best grasses are equally within their reach, should still prefer those grasses which naturally grow on the Welsh mountains: it seems to argue that such a preference is the effect of some other cause than that of habit.

"*Festuca ovina*, sheep's fescue. All kinds of cattle relish this grass; but it appears from the trial that has been made with it on clayey soils, that it continues but a short time in possession of such, being soon overpowered by the more luxuriant kinds. On dry shallow soils that are incapable of producing the larger sorts, this should form the principal crop, or rather the whole; for it is seldom or ever, in its natural state, found intimately mixed with others, but by itself.

"*Festuca duriuscula*, hard fescue grass. This is certainly one of the best of the dwarf sorts of grasses. It is grateful to all kinds of cattle; hares are very fond of it; they cropped it close to the roots, and neglected the *Festuca ovina* and *Festuca rubra*, which were contiguous to it. It is present in most good meadows and pastures.

"*Festuca pratensis*, meadow fescue. This grass is seldom absent from rich meadows and pastures; it is observed to be highly grateful to oxen, sheep, and horses, particularly the former. It appears to grow most luxuriantly when combined with the hard fescue and *Poa trivialis*.

"*Avena elatior*, tall oat grass. This is a very productive grass, frequent in meadows and pastures, but is disliked by cattle, particularly by horses; this perfectly agrees with the small portion of nutritive matter which it affords. It seems to thrive best on a strong tenacious clay.

"*Avena flavescens*, yellow oat-grass. This grass seems partial to dry soils and meadows, and appears to be eaten by sheep and oxen equally with the meadow barley, crested dog's-tail, and sweet-scented vernal grasses, which naturally grow in company with it. It nearly doubles the quantity of its produce by the application of calcareous manure.

"*Holcus lanatus*, meadow soft grass. This is a very common grass, and grows on all soils, from the richest to the poorest. It affords an abundance of seed, which is light, and easily dispersed by the wind. It appears to be generally disliked by all sorts of cattle. The produce is not so great as a view of it in fields would indicate; but being left almost entirely untouched by cattle, it appears as the most productive part of the herbage. The hay which is made of it, from the ble to the state of natural food. Thus, when sugar is given to them, some dry fibrous matter should be mixed with it, such as chopped straw, or dry withered grass, in order that the functions of the stomach and bowels may be performed in a natural manner. The principle is the same as that of the practice alluded to in the third lecture, of giving chopped straw with barley.

In washing sheep, the use of water containing carbonate of lime should be avoided; for this substance decomposes the yolk of the wool, which is an animal soap, the natural defence of the wool; and wool often washed in calcareous water becomes rough and more brittle. The finest wool, such as that of the Spanish and Saxon sheep, is most abundant in yolk. M. Vauquelin has analyzed several different species of yolk, and has found the principal part of all of them a soap, with a basis of potassa (*i. e.* a compound of oily matter and potassa,) with a little oily matter in excess. He has found in them, likewise, a notable quantity of acetate of potassa, and minute quantities of carbonate of potassa, and muriate of potassa, and a peculiar odorous animal matter.

M. Vauquelin states, that he found some specimens of wool lose as much as 45 per cent. in being deprived of their yolk; and the smallest loss in his experiments was 35 per cent.

The yolk is most useful to the wool on the back of the sheep in cold and wet seasons; probably the application of a little soap of potassa, with excess of grease to the sheep brought from warmer climates in our winter, that is, increasing their yolk artificially, might be useful in cases where the fineness of the wool is of great importance. A mixture of this kind is more conformable to nature than that ingeniously adopted by Mr. Bakewell; but at the time his labors commenced the chemical nature of the yolk was unknown.

I have now exhausted all the subjects of discussion, which my experience or information has been able to supply, on the connexion of chemistry with agriculture.

I venture to hope that some of the views brought forward may contribute to the improvement of the most important and useful of the arts.

I trust that the inquiry will be pursued by others; and that, in proportion as chemical philosophy advances towards perfection, it will afford new aids to agriculture.

There are sufficient motives, connected both with pleasure and profit, to encourage ingenious men to pursue this new path of investigation. Science cannot long be despised by any persons as the mere speculation of theorists; but must soon be considered by all ranks of men in its true point of view, as the refinement of common sense, guided by experience, gradually substituting sound and rational principles for vague popular prejudices.

The soil offers inexhastible resources, which when properly appreciated and employed, must increase our wealth, our population, and our physical strength.

We possess advantages in the use of machinery, and the division of labor, belonging to no other nation. And the same energy of character, the same extent of resources which has always distinguished the people of the British Islands, and made them excel in arms, commerce, letters, and philosophy, apply with the happiest effect to the improvement of the cultivation of the earth. Nothing is impossible to labor, aided by ingenuity. The true objects of the agriculturist are likewise those of the patriot. Men value most what they have gained with effort; a just confidence in their own powers results from success; they love their country better, because they have seen it improved by their own talents and industry; and they identify with their interests the existence of those institutions which have afforded them security, independence, and the multiplied enjoyments of civilized life.

APPENDIX.

AN ACCOUNT OF THE RESULTS OF EXPERIMENTS ON THE PRODUCE AND NUTRITIVE QUALITIES OF DIFFERENT GRASSES, AND OTHER PLANTS, USED AS THE FOOD OF ANIMALS. INSTITUTED BY JOHN DUKE OF BEDFORD.

Introduction by Sir H. Davy.

Of the 215 proper grasses which are capable of being cultivated in this climate, two only have been employed to any extent for making artificial pastures,—rye-grass and cock's-foot grass; and their application for this purpose seems to have been rather the result of accident than of any proofs of their superiority over other grasses.

A knowledge of the comparative merits and value of all the different species and varieties of grasses cannot fail to be of the highest importance in practical agriculture. The hope of obtaining this knowledge was the motive that induced the Duke of Bedford to institute this series of experiments.

Spots of ground, each containing four square feet, in the garden at Woburn Abbey, were inclosed by boards in such a manner that there was no lateral communication between the earth included by the boards and that of the garden. The soil was removed in these inclosures, and new soils supplied; or a mixture of soils was made in them, to furnish as far as possible to the different

---

number of downy hairs which cover the surface of the leaves, is soft and spongy, and disliked by cattle in general.

"*Anthoxanthum odoratum*, sweet-scented vernal grass. Horses, oxen, and sheep eat this grass; though in pastures where it is combined with the meadow fox-tail, and white clover, cock's-foot, rough-stalked meadow, it is left untouched; from which it would seem unpalatable to cattle. Mr. Grant of Leighton laid down one-half a field of a considerable extent with this grass, combined with white clover. The other half of the field with fox-tail and red clover. The sheep would not touch the sweet-scented vernal, but kept constantly upon the fox-tail. The writer of this saw the field when the grasses were in the highest state of perfection; and hardly any thing could be more satisfactory. Equal quantities of the seeds of white clover were sown with each of the grasses; but from the dwarf nature of the sweet-scented vernal grass, the clover mixed with it had attained to greater luxuriance than that mixed with the meadow fox-tail."

grasses those soils which seem most favorable to their growth; a few varieties being adopted for the purpose of ascertaining the effect of different soils on the same plant.

The grasses were either planted or sown, and their produce cut and collected and dried, at the proper seasons, in summer and autumn, by Mr. Sinclair, his grace's gardener. For the purpose of determining, as far as possible, the nutritive powers of the different species, equal weights of the dry grasses or vegetable substances were acted upon by hot water till all their soluble parts were dissolved; the solution was then evaporated to dryness by a gentle heat in a proper stove, and the matter obtained carefully weighed. This part of the process was likewise conducted with much address and intelligence by Mr. Sinclair, by whom all the following details and calculations are furnished.

The dry extracts, supposed to contain the nutritive matter of the grasses, were sent to me for chemical examination. The composition of some of them is stated in a foregoing table; I shall offer a few chemical observations on others at the end of this appendix. It will be found from the general conclusions, that the mode of determining the nutritive power of the grasses, by the quantity of matter they contain soluble in water, is sufficiently accurate for all the purposes of agricultural investigation.

I. *Anthoxanthum odoratum.* Engl. Bot. 647. Curt. Lond.

Sweet-scented vernal-grass. Nat. of Britain.

At the time of flowering, the produce from the space of an acre equal to ·000091827364 of a brown sandy loam with manure, is—

	oz.	or lbs. per acre.
Grass, 11 oz. 8 dr.* The produce per acre	125235 0 =	7827 3 0
80 dr. of grass weigh when dry . 21½ dr. The produce of the space, ditto 49.1$\frac{3}{10}$	33656 0 =	2103 8 0
The weight lost by the produce of one acre in drying . .	. .	5723 10 0
64 dr. of grass afford of nutritive matter 1 dr. The produce of the space, ditto . 2.3$\frac{5}{10}$	1956 12 =	122 4 12

At the time the seed is ripe, the produce is—

	oz.	or lbs. per acre.
Grass 9 oz. The produce per acre .	98010 0 =	6125 10 0
80 dr. of grass weigh when dry . . 24 dr. The produce of the space, ditto . 43$\frac{1}{16}$	29403 0 =	1837 11 0
The weight lost by the produce of one acre in drying . .	. .	4287 15 0
64 dr. of grass afford of nutritive matter 3.1 dr. The produce of the space, ditto . 7.1¼	4977 10 =	311 1 1
The weight of nutritive matter which is lost by taking the crop at the time the grass is in flower, exceeding half of its value . .	. .	188 12 4

The proportional value which the grass at the time of flowering bears to that at the time the seed is ripe, is as 4 to 13.

The latter-math produce is—

	oz.	or lbs. per acre.
Grass, 10 oz. The produce per acre . .	108900 0 =	6806 4 0
64 dr. of grass afford of nutritive matter 2.1 dr.	3828 8 =	239 4 8

The proportional value which the grass of the latter-math bears to that at the time the seed is ripe, is nearly as 9 to 13.

The smallness of the produce of this grass renders it improper for the purpose of hay; but its early growth, and the superior quantity of nutritive matter which the latter-math affords, compared with the quantity afforded by the grass at the time of flowering, causes it to rank high as a pasture grass, on such soils as are well fitted for its growth; such are peat-bogs, and lands that are deep and moist,

II. *Holcus odoratus.* Host. G. A. Growing in woods.

Sweet-scented soft grass. Nat. of Germany. Flo. Ger. — H. borealis. Growing in moist meadows.

At the time of flowering, the produce from a rich sandy loam is—

	oz.	or lbs. per acre.
Grass, 14 oz. The produce per acre .	152460 0 =	9528 12 0
80 dr. of grass weigh when dry 20.2 dr. The produce of the space, ditto 57.1$\frac{3}{5}$	39067 14 =	2441 11 14
The weight lost by the produce of one acre in drying . .	.	7087 0 2
64 dr. of grass afford of nutritive matter 4.1 dr. The produce of the space, ditto 14.3½	10124 13 =	610 15 5

At the time the seed is ripe, the produce is—

	oz.	or lbs. per acre.
Grass, 40 oz. The produce per acre .	435600 0 =	27225 0 0

---

* The weight is avoirdupois; lbs. pounds, oz. ounces, dr. drachms. The weights not named are quarters of drachms, and fractions of quarters of drachms; thus 7.1¼ means 7 drachms, 1 quarter of a drachm, and ¼ of a quarter.

	oz.	or lbs. per acre.		
64 dr. of grass weigh when dry . . 28 dr. The produce of the space ditto . . 224	152460	0= 9528	12	0
The weight lost by the produce of one acre in drying		17696	4	0
64 dr. of grass afford of nutritive matter 5.1 dr. The produce of the space, ditto . . 52.2	35732	13= 2233	4	13
The weight of nutritive matter which is lost by taking the crop at the time the grass is in flower, being more than half of its value		1600	8	10

The proportional value which the grass at the time of flowering bears to that at the time the seed is ripe, is as 17 to 21.

The produce of latter-math is—

Grass, 25 oz. The produce per acre	272250	0=17015	10	0
64 dr. of grass afford of nutritive matter 4.1 dr. .	18079	1= 1129	15	1

The grass of the latter-math crop, and of the crop at the time of flowering, taking the whole quantity, and their relative proportions of nutritive matter, are in value nearly as 6 to 10; the value of the grass at the time the seed is ripe exceeds that of the latter-math in proportion as 21 to 17.

Though this is one of the earliest of the flowering grasses, it is tender, and the produce in the spring is inconsiderable. If, however, the quantity of nutritive matter which it affords be compared with that of any of those species which flower nearly at the same time, it will be found greatly superior. It sends forth but a small number of flower-stalks, which are of a slender structure compared to the size of the leaves. This will account in a great measure for the equal quantities of nutritive matter afforded by the grass at the time of flowering, and the latter-math.

III. *Cynosurus cæruleus.* Engl. Bot. 1613. Host. G. A. ii. t. 98.

Blue moor-grass. Nat. of Britain. Sesleria cærulea.

At the time the seed is ripe, the produce from a light sandy soil is—

Grass, 10 oz. The produce per acre	1089000	0=6806	4	0
64 dr. of grass afford of nutritive matter 3.3 dr. . .	6380	13= 398	12	13

The produce of this grass is greater than its appearance would denote; the leaves seldom attain to more than four or five inches in length, and the flower stalks seldom rise to more. Its growth is not rapid after being cropped, nor does it seem to withstand the effects of frost, which, if it happen to be severe and early in the spring, checks it so much as to prevent it from flowering for that season; otherwise the quantity of nutritive matter which the grass affords (for the straws are very inconsiderable) would rank it as a valuable grass for permanent pasture.

IV. *Alopecurus pratensis.* Curt. Lond. Alo. myosuroides. Meadow fox-tail grass. Nat. of Brit. Engl. Bot. 848.

At the time of flowering, the produce from a clayey loam is—

	oz.	or lbs. per acre.		
Grass, 30 oz. The produce per acre . . .	326700	0=20418	12	0
80 dr. of grass weigh when dry . . 24 dr. The produce of the space, ditto . . 336	98010	0= 6125	10	0
The weight lost by the produce of one acre in drying . . .		14293	2	0
64 dr. of grass afford of nutritive matter 1.2 dr. The produce of the space, ditto . . 11.1	7657	0= 478	9	0

The produce from a sandy loam is—

Grass, 12 oz. 8 dr. The produce per acre . .	136125	0= 8507	13	0
80 dr. of grass weigh when dry . . 24 dr. The produce of the space, ditto . . 60	40837	9= 2552	5	8
64 dr. of grass afford of nutritive matter 1 The produce of the space, ditto . . 3.0½	2126	15= 132	14	15

At the time the seed is ripe, the produce from the clayey loam is—

Grass, 19 oz. The produce per acre . . .	206910	0=12931	14	0
80 dr. of grass weigh when dry . . . 36 dr. The produce of the space, ditto . . 136.3⅕	93109	8= 5819	5	2
The weight lost by the produce of one acre in drying . .		7111	8	14
64 dr. of grass afford of nutritive matter 2.1 dr. The produce of the space, ditto . . 9.975	7376	4= 461	0	4
The weight of nutritive matter which is lost by leaving the crop till the seed be ripe, being one twenty-fifth part of its value		17	8	11

The proportional value which the grass at the time of flowering bears to that at the time the seed is ripe, is as 6 to 9.

The latter-math produce, from the clayey loam, is—

Grass, 12 oz. The produce per acre . . .	130680	0= 8167	8	0
64 dr. of grass afford of nutritive matter 2 dr. The produce of the space, ditto . . 6	4083	12= 255	3	12

The proportional value which the whole of the latter-math crop bears to that at the time the seed is ripe, is as 5 to 9, and to that at the time of flowering, proportionably as 13 to 24.

The above statement clearly shows that there is nearly three-fourths of produce greater from a clayey loam than from a sandy soil, and the grass from the latter is comparatively of less value, in proportion as 4 to 6. The straws produced by the sandy soil are deficient in number, and in every respect less than those from the clayey loam; which will account for the unequal quantities of nutritive matter afforded by them; but the proportional value in which the grass of the latter-math exceeds that of the crop at the time of flowering, is as 4 to 3: a difference which appears extraordinary, when the quantity of flower-stalks which are in the grass at the time of flowering is considered. In the *Anthoxanthum odoratum* the proportional difference between the grass of these crops is still greater, nearly as 4 to 9: in the *Poa pratensis* they are equal; but in all the latter flowering grasses experimented upon, the flowering straws of which resemble those of the *Alopecurus pratensis*, or *Anthoxanthum odoratum*, the greater proportional value is always, on the contrary, found in the grass of the flowering crop. Whatever the cause may be, it is evident that the loss sustained by taking the crops of these grasses at the time of flowering is considerable.

V. *Alopecurus alpinus.* Engl. Bot. 1126.
Alpine fox-tail grass. Nat. of Scotland.

At the time of flowering, the produce from a sandy loam with a small portion of manure, is—

	oz.		or lbs. per acre.		
Grass, 8 oz. The produce per acre . .	87120	0=	5445	5	0
60 dr. of grass weigh when dry . . 16 dr. The produce of the space, ditto . . $34\frac{2}{16}$	23232	0=	1452	0	0
The weight lost by the produce of one acre in drying . . .			3993	5	0
64 dr. of grass afford of nutritive matter 1 dr. . The produce of the space, ditto . . . 2	1361	4=	85	1	4

VI. *Poa alpina.* Engl. Bot. 1003. Flor. Dan. 107.
Alpine meadow grass. Nat. of Scotland.

At the time of flowering, the produce from a light sandy loam is—

Grass, 8 oz. The produce per acre . .	87120	0=	5445	0	0
64 dr. of grass afford of nutritive matter . 1.2 dr.	2041	14	127	9	14

VII. *Avena pubescens.* Engl. Bot. 1640. Host. G. A. ii. t. 50.
Downy oat-grass. Nat. of Britain.

At the time of flowering, the produce from a rich randy soil is—

Grass, 23 oz. The produce per acre . .	250470	0=	15654	6	0
80 dr. of grass weigh when dry . . 30 dr. The produce of the space, ditto . . 138 dr.	93926	0=	5870	6	4
The weight lost by the produce of one acre in drying . . .			9783	15	12
64 dr. of grass afford of nutritive matter 1.2 dr. The produce of the space, ditto . $8.2\frac{2}{16}$	5870	0=	366	14	6

At the time the seed is ripe, the produce is—

Grass 10 oz. The produce per acre . .	108900	0=	6806	4	0
80 dr. of grass weigh when dry . . 16 dr. The produce of the space, ditto . . 32	21780	0=	1361	4	0
The weight lost by the produce of one acre in drying . . .			5545	0	0
64 dr. of grass afford of nutritive matter . 2 dr. The produce of the space, ditto . . . 5	3403	2=	212	11	0
The weight of nutritive matter which is lost by leaving the crop till the seed be ripe, being more than half of its value			154	6	3

The proportional value which the grass at the time of flowering bears to that at the time the seed is ripe, is as 6 to 8.

The produce of latter-math is—

	oz.		or lbs. per acre.		
Grass, 10 oz. The produce per acre . .	108900	0=	6806	4	0
64 dr. of grass afford of nutritive matter . 2 dr.	3403	2=	212	11	0

The proportional value which the grass at the time of flowering bears to that of the latter-math, is as 6 to 8. The grass of the seed-crop, and that of the latter-math, are of equal value.

The downy hairs which cover the surface of the leaves of this grass, when growing on poor light soils, almost entirely disappear when it is cultivated on a richer soil. It possesses several good qualities which recommend it to particular notice; it is hardy, early, and more productive than many others which affect similar soils and situations. Its growth after being cropped is tolerably rapid, although it does not attain to a great length if left growing: like the *Poa pratensis*, it sends forth flower-stalks but once in a season, and it appears well calculated for permanent pasture on rich light soils.

VIII. *Poa pratensis.* Curt. Lond. Engl. Bot. 1073.
Smooth-stalked meadow grass. Nat. of Britain.

At the time of flowering, the produce from a mixture of bog-earth and clay is—

Grass, 15 oz. The produce per acre . .	163350	0=	10209	6	0
80 dr. of grass weigh when dry . . 22.2 dr. The produce of the space, ditto . . 67.2	45942	3=	2871	6	3
The weight lost by the produce of one acre in drying . . .			7337	15	13
34 dr. of grass afford of nutritive matter . 1.3 dr. The produce of the space, ditto . . $6.2\frac{1}{16}$	4466	9=	279	2	9

At the time the seed is ripe, the produce is—

Grass, 12·8 oz. The produce per acre .	136125	0=	8507	13	0
80 dr. of grass weigh when dry . . 32 dr. The produce of the space, ditto . . . 80	5445	0=	3403	2	0
The weight lost by the produce of one acre in drying . .			5104	11	0
64 dr. of grass afford of nutritive matter 1.2 dr. The produce of the space, ditto . . $4.2\frac{3}{16}$	3190	6=	199	6	0
The weight of nutritive matter which is lost by leaving the crop till the seed be ripe, being nearly one-fourth of its value . . .			79	12	9

The produce of latter-math is—

Grass, 6 oz. The produce per acre . .	65340	0=	4083	12	0
64 dr. of grass afford of nutritive matter 1.3 dr.	1786	10=	111	10	0

The proportional value in which the grass of the latter-math exceeds that of the flowering crop, is as 6 to 7. The grass of the seed-crop and that of the latter-math are of equal value.

This grass is, therefore, of least value at the time the seed is ripe; a loss of more than one-fourth of the value of the whole crop is sustained if it is not cut till that period: the straws are then dry, and the root-leaves in a sickly decaying state; those of the latter-math, on the contrary, are luxuriant and healthy. This species sends forth flower-stalks but once in a season; and these being the most valuable part of the plant for the purpose of hay, it will, from this circumstance, and the superior value of the grass of the latter-math compared to that of the seed-crop, appear well adapted for permanent pasture.

IX. *Poa cærulea.*—Var. *Poa pratensis.* Engl. Bot. 1004.

Poa subcærulea. Short bluish meadow-grass. Nat. of Britain. H. Kew. 1—155 Poa humilis.

At the time of flowering, the produce from a soil of the like nature as the preceding is—

	oz.		or lbs. per acre.		
Grass, 11 oz. The produce per acre . .	119790	0=	7486	14	0
64 dr. of grass afford of nutritive matter 2 dr. The produce of the space, ditto . . 5·2	3743	7=	233	15	0
80 dr. of grass weigh when dry . . 24 The produce of the space, ditto . . 52·3 3/16	35937	0=	2246	1	0
The weight lost by the produce of one acre in drying . . .	.	.	5240	13	0

If the produce of this variety be compared with that of the preceding one, it will be found less; nor does it seem to possess any superior excellence. The superior nutritive power does not make up for the deficiency of produce by 80 lbs. of nutritive matter per acre.

X. *Festuca hordiformis.* Poa hordiformis. H. Cant.

Barley-like fescue grass. Nat. of Hungary.

At the time of flowering, the produce from a sandy soil, with manure, is—

Grass, 20 oz. The produce per acre . .	217800	0=	13612	8	0
80 dr. of grass weigh when dry . . 24 dr. The produce of the space, ditto . 96	65340	0=	4083	12	0
The weight lost by the produce of one acre in drying . . .	.	.	9528	12	0
64 dr. of grass afford of nutritive matter 2·1 dr. The produce of the space, ditto . . 11·1	7657	0=	478	9	0

This is rather an early grass, though later than any of the preceding species; its foliage is very fine, resembling the *F. duriuscula*, to which it seems nearly allied, differing only in the length of the awns, and the glaucous color of the whole plant. The considerable produce it affords, and the nutritive powers it appears to possess, joined to its early growth, are qualities which strongly recommend it to further trial.

XI. *Poa trivialis.* Curt. Lond. Engl. Bot. 1072. Host. G. A. ii. t. 62.

Roughish meadow-grass. Nat. of Britain.

At the time of flowering, the produce from a light brown loam, with manure, is—

	oz.		or lbs. per acre.		
Grass, 11 oz. The produce per acre . .	119790	0=	7486	14	0
80 dr. of grass weigh when dry . . 24 dr. The produce of the space, ditto . 45 3/16	35937	0=	2246	1	0
The weight lost by the produce of one acre in drying			5240	13	0
64 dr. of grass afford of nutritive matter 2 dr. The produce of the space, ditto . . 5.2	3743	7=	233	15	7

At the time the seed is ripe, the produce is—

Grass, 11·8 oz. The produce per acre .	125235	0=	7827	3	0
80 dr. of grass weigh when dry . . 36 dr. The produce of the space, ditto . 82.3 3/16	56355	12=	3522	3	12
The weight lost by the produce of one acre in drying			4304	15	4
64 dr. of grass afford of nutritive matter 2.3 dr. The produce of the space, ditto . . 7.3 3/5	5381	3=	336	5	3
The weight of nutritive matter which is lost by taking the crop at the time of flowering, exceeding one-fourth of its value			102	5	12

The proportional value in which the grass of the seed-crop exceeds that at the time of flowering, is as 8 to 11.

The produce of the latter-math is—

Grass, 7 oz. The produce per acre . .	76230	0=	4764	6	0
64 dr. of grass afford of nutritive matter 3 dr.	3573	4=	223	5	4

The proportional value by which the grass of the latter-math exceeds that of the flowering crop, is as 8 to 12, and that of the seed-crop as 11 to 12.

Here, then, is a satisfactory proof of the superior value of the crop at the time the seed is ripe, and of the consequent loss sustained by taking it when in flower; the produce of each crop being nearly equal. The deficiency of hay in the flowering crop, in proportion to that of the seed-crop, is very striking. Its superior produce, the highly nutritive powers which the grass seems to possess, and the season in which it arrives at perfection, are merits which distinguish it as one of the most valuable of those grasses which affect moist rich soils and sheltered situations; but on dry exposed situations it is altogether inconsiderable: it yearly diminishes, and ultimately dies off, not unfrequently in the space of four or five years.

XII. *Festuca glauca.* Curtis.

Glaucous fescue-grass. Nat. of Britain.

At the time the seed is ripe, the produce from a brown loam is—

Grass, 14 oz. The produce per acre . .	152460	0=	9528	12	0
80 dr. of grass weigh when dry . 32 dr. The produce of the space, ditto . 89.2 $\frac{1.2}{16.32}$	60984	0=	3811	8	0
The weight lost by the produce of one acre in drying . .			5717	4	0
64 dr. of grass afford of nutritive matter 1.2 dr. The produce of the space, ditto . . 5.1	2573	4=	223	5	4

At the time of flowering, the produce is—

	oz.		or lbs. per acre.		
Grass, 14 oz. The produce per acre . .	152460	0=	9528	12	0
80 dr. of grass weigh when dry . . 32 dr. The produce of the space, ditto . . 89.2$\frac{3}{5}$	60984	0=	4811	8	0
The weight lost by the produce of one acre in drying . .			5717	4	0
64 dr. of grass afford of nutritive matter 3 dr. The produce of the space, ditto . . 10.2	7146	9=	446	10	9
The weight of nutritive matter which is lost by leaving the crop till the seed be ripe, being half of the value of the crop . . .			223	5	5

The proportional value by which the grass at the time of flowering exceeds that at the time the seed is ripe, is as 6 to 12.

The proportional difference in the value of the flowering and seed crops of this grass is directly the reverse of that of the preceding species, and affords another strong proof of the value of the straws in grass which is intended for hay. The staws at the time of flowering are of a very succulent nature; but from that period till the seed be perfected, they gradually become dry and wiry. Nor do the root-leaves sensibly increase in number or in size, but a total suspension of increase appears in every part of the plant, the roots and seed-vessels excepted. The straws of the *Poa trivialis* are, on the contrary, at the time of flowering, weak and tender; but as they advance towards the period of ripening the seed, they become firm and succulent: after that period, however, they rapidly dry up, and appear little better than a mere dead substance.

XIII. *Festuca glabra.* Wither. B. ii. p. 154.
Smooth fescue-grass. Nat. of Scotland.

At the time of flowering, the produce from a clayey loam with manure is—

Grass, 21 oz. The produce per acre . .	228690	0=	14293	0	0
80 dr. of grass weigh when dry . 32 dr. The produce of the space, ditto . 134.1$\frac{2}{16}$.$\frac{2}{5}$	91476	0=	5717	4	0
The weight lost by the produce of one acre in drying . .			8576	14	0
64 dr. of grass afford of nutritive matter 2 dr. The produce of the space, ditto . 10.2	7146	0=	446	10	0

At the time the seed is ripe, the produce is—

Grass, 14 oz. The produce per acre .	152460	0=	9528	12	0
80 dr. of grass weigh when dry . 32 dr. The produce of the space, ditto . 89.2$\frac{3}{5}$	60984	0=	3811	8	0
The weight lost by the produce of one acre in drying . .			5717	4	0
64 dr. of grass afford of nutritive matter 1.1 dr. The produce of the space, ditto . 4.1$\frac{3}{4}$	2977	11=	186	1	11
The weight of nutritive matter which is lost by leaving the crop till the seed be ripe, exceeding half of its value .			260	9	0

The proportional value which the grass at the time the seed is ripe bears to that of the crop at the time of flowering, is as 5 to 8.

The produce of latter-math is—

	oz.		or lbs. per acre.		
Grass, 9 oz. The produce per acre . .	98010	0=	6125	10	0
64 dr. of grass afford of nutritive matter 2 dr. The produce of the space, ditto . 1.0$\frac{1}{2}$ dr.	765	11=	47	13	0

The proportional value which the grass of the latter-math bears to that of the crop at the time of flowering is as 2 to 8, and to that of the crop at the time the seed is ripe is as 2 to 5.

The general appearance of this grass is very similar to that of the *Festuca duriuscula*: it is, however, specifically different, and inferior in many respects, which will be manifest on comparing their several produce with each other; but if it be compared with some others, now under general cultivation, the result is much in its favor, the soil which it affects being duly attended to. The *Anthoxanthum odoratum* being taken as an example, it appears that

Festuca glabra affords of nutritive matter—

	lbs. per acre.	
From the crop at the time of flowering	446	632
At the time the seed is ripe, ditto .	186	

Anthoxanthum odoratum,

At the time of flowering, ditto .	122	433
At the time the seed is ripe, ditto .	311	
The weight of nutritive matter which is afforded by the produce of one acre of the *Festuca glabra*, exceeding that of the *Anthoxanthum odoratum* in proportion nearly as 6 to 9 . .		199

XIV. *Festuca rubra.* Wither. B. ii. p. 153.
Purple fescue-grass. Nat. of Britain.

At the time of flowering, the produce from a light sandy soil is—

Grass, 15 oz. The produce per acre . .	163350	0 =	10209	6	0
80 dr. of grass weigh when dry . . 34 dr. The produce of the space, ditto . . 102	56923	12=	3557	11	0
The weight lost by the produce of one acre in drying			6651	11	0
64 dr. of grass afford of nutritive matter 1.2 dr. The produce of the space, ditto . . 22$\frac{2}{16}$	3828	8=	239	4	8

At the time the seed is ripe, the produce is—

Grass, 16 oz. The produce per acre . .	174240	0=	10890	0	0
80 dr. of grass weigh when dry . . 36 dr. The produce of the space, ditto . . 115$\frac{3}{16}$	78408	0=	4900	8	0
The weight lost by the produce of one acre in drying			5989	8	0
64 dr. of grass afford of nutritive matter 2 dr. The produce of the space, ditto . . 8	5445	0=	340	5	0
The weight of nutritive matter which is lost by taking the crop when the grass is in flower, being nearly one-third part of its value . .			101	0	8

The proportional value which the grass at the time of flowering bears to that at the time the seed is ripe, is as 6 to 8.

This species is smaller in every respect than the preceding. The leaves are seldom more than from three to four inches in length; it affects a soil similar to that favorable to the growth of the *Festuca ovina*, for which it would be a profitable substitute, as will clearly appear on a comparison of their produce with each other.

The produce of latter-math is—

	oz.		or lbs. per acre.		
Grass, 5 oz. The produce per acre . .	54450	0=	3403	2	0
64 dr. of grass afford of nutritive matter . 1.2 dr.	1276	2=	79	12	0

The proportional value which the grass of the latter-math bears to that at the time the seed is ripe, is as 6 to 8, and is of equal value with the grass at the time of flowering.

XV. *Festuca ovina*. Engl. Bot. 585. Wither. B. ii. p. 152.

Sheep's fescue grass. Nat. of Britain.

At the time the seed is ripe, the produce is—

Grass, 8 oz. The produce per acre . .	87120	0=	5445	0	0
64 dr. of grass afford of nutritive matter 1.2 dr. The produce of the space, ditto . . 3	2031	14=	127	9	0

The produce of latter-math is—

Grass, 5 oz. The produce per acre . .	54450	0=	3403	2	0
64 dr. of grass afford of nutritive matter 1.1 dr.	1063	7=	66	7	7

The dry weight of this species was not ascertained, because the smallness of the produce renders it entirely unfit for hay. If the nutritive powers of this species be compared with those of the preceding, the inferiority will appear thus:

Festuca ovina affords of nutritive matter		1.2	2.3
Ditto	ditto	1.1	
Festuca rubra	ditto	2	3.2
Ditto	ditto	1.2	

The comparative degree of nourishment which the grass of the *Festuca rubra* affords exceeds therefore that afforded by the *F. ovina* in proportion as 11 to 14.

From the trial that is here detailed, it does not seem to possess the nutritive powers generally ascribed to it; it has the advantage of a fine foliage, and may, therefore, very probably, be better adapted to the masticating organs of sheep than the larger grasses, whose nutritive powers are shown to be greater: hence, on situations where it naturally grows, and as pasture for sheep, it may be inferior to few others. It possesses natural characters very distinct from *F. rubra*.

XVI. *Briza media*. Engl. Bot. 340. Host. G. A. ii. t. 29.

Common quaking-grass. Nat. of Britain.

At the time of flowering, the produce from a rich brown loam is—

	oz.		or lbs. per acre.		
Grass, 14 oz. The produce per acre . .	152460	0=	9528	12	0
80 dr. of grass weigh when dry . . 26 dr. The produce of the space ditto . . 72.3$\frac{1}{16}$	49549	8=	3096	13	8
The weight lost by the produce of one acre in drying . . .			6431	14	8
64 dr. of grass afford of nutritive matter 2.3 dr. The produce of the space, ditto . . 9.2$\frac{2}{16}$	6551	0=	409	7	0

At the time the seed is ripe, the produce is—

Grass, 14 oz. The produce per acre . .	152460	0=	9528	12	0
80 dr. of grass weigh when dry . . 28 dr. The produce of the space, ditto . 78.1$\frac{3}{5}$	53362	0=	3335	1	0
The weight lost by the produce of one acre in drying . . .			6183	11	0
64 dr. of grass afford of nutritive matter 3.1 dr. The produce of the space, ditto . . 11.1$\frac{1}{2}$	7742	1=	483	14	1
The weight of nutritive matter which is lost by taking the crop at the time of flowering, being nearly one-fourth part of its value . . .			109	1	0

The proportional value which the grass at the time of flowering bears to that at the time the seed is ripe, is as 11 to 13.

The latter-math produce is—

Grass, 12 oz. The produce per acre . .	130680	0=	8167	8	0
64 dr. of grass afford of nutritive matter 2 dr. .	483	12=	255	3	12

The proportional value in which the grass at the time of flowering exceeds that of the latter-math, is as 8 to 11; and the latter-math stands to that at the time the seed is ripe in proportion as 8 to 13.

The merits of this grass seem to demand notice: its nutritive powers are considerable, and its produce large when compared with others which affect a similar soil.

XVII. *Dactylis glomerata*. Engl. Bot. 335. Fl. Dan. 743.

Round-headed cock's-foot grass. Nat. of Britain. Wither. B. ii. p. 149.

At the time of flowering, the produce from a rich sandy loam is—

Grass, 41 oz. The produce per acre . .	446490	0=	27905	10	0
80 dr. of grass weigh when dry . 34 dr. The produce of the space, ditto . 278$\frac{4}{5}$	189758	4=	11859	14	4
The weight lost by the produce of one acre in drying . .			16045	11	12
64 dr of grass afford of nutritive matter 2.2 dr. The produce of the space, ditto . 25.2$\frac{1}{2}$	17424	0=	1089	0	0

At the time the seed is ripe, the produce is—

Grass, 39 oz. The produce per acre .	424710	0=	26544	6	0
80 dr. of grass weigh when dry . 40 dr. The produce of the space, ditto . 312	21235	0=	13272	3	0
The weight lost by the produce of one acre . . .			13272	3	0
64 dr. of grass afford of nutritive matter 3.2 dr. The produce of the space, ditto , 34.0$\frac{1}{2}$	23226	5=	1451	10	0
The weight of nutritive matter which is gained by leaving the crop till the seed be ripe, being more than one-third part of its value, is . .			362	10	5

The proportional value which the grass at the time of flowering bears to that at the time the seed is ripe, is as 5 to 7, nearly.

The produce of latter-math is—

	oz.	or lbs. per acre.
Grass, 17 oz. 8 dr. The produce per acre .	190575	0=11910 15 0
64 dr. of grass afford of nutritive matter 1.2 dr.	4466	9= 281 10 9

The proportional value which the grass of the latter-math bears to that at the time of flowering is as 6 to 10; and to that at the time the seed is ripe, as 6 to 14. 64 dr. of the straws at the time of flowering afford of nutritive matter 1.2 dr. The leaves or latter-math, and the straws simply, are therefore of equal proportional value; a circumstance which will point out this grass to be more valuable for permanent pasture than for hay. The above details prove, that a loss of nearly one-third of the value of the crop is sustained if it is left till the period when the seed is ripe, though the proportional value of the grass at that time is greater, *i. e.* as 7 to 5. The produce does not increase if the grass is left growing after the period of flowering, but uniformly decreases; and the loss of latter-math, which (from the rapid growth of the foliage after the grass is cropped) is very considerable. These circumstances point out the necessity of keeping this grass closely cropped, either with the scythe or cattle, to reap the full benefit of its great merits.

XVIII. *Bromus tectorum.* Host. G. A. i. t. 15. Nodding panicled brome-grass. Nat. of Europe. Introduced 1776. H. K. i. 168.

At the time of flowering, the produce from a light sandy soil is—

Grass, 11 oz. The produce per acre .	119790	0= 7486 14 0
80 dr. of grass weigh when dry . 42 dr. The produce of the space, ditto : $92.1\frac{3}{5}$	62889	12= 3930 9 12
The weight lost by the produce of one acre in drying . .		3556 4 4
64 dr. of grass afford of nutritive matter 3 dr. The produce of the space, ditto . 8.1	5615	2= 350 15 2

This species, being strictly annual, affords no latter-math, which renders it comparatively of little value.

XIX. *Festuca cambrica.* Hudson. W. B. ii. p. 155. Nat. of Britain.

At the time of flowering, the produce from a light sandy soil is—

Grass, 10 oz. The produce per acre .	108900	0= 6806 4 0
80 dr. of grass weigh when dry . 34 dr. The produce of the space, ditto . 68	46282	8= 2892 10 8
The weight lost by the produce of one acre in drying . .		3913 9 8
64 dr. of grass afford of nutritive matter 2.1 dr. The produce of the space, ditto . $5.2\frac{1}{2}$	3828	8= 239 4 8

This species is nearly allied to the *Festuca ovina*, from which it differs little, except that it is larger in every respect. The produce, and the nutritive matter which it affords, will be found superior to those given by the *F. ovina*, if they are brought into comparison.

XX. *Bromus diandrus.* Curt. Lond. Eng. Bot. 1006 Nat. of Britain.

At the time the grass is ripe in flower, the produce from a rich brown loam is—

	oz.	or lbs. per acre.
Grass, 30 oz. The produce per acre . . .	326700	0=20418 12 0
80 dr. of grass weigh when dry . . . 34 dr. The produce of the space, ditto . . 204	138847	8= 8677 15 0
The weight lost by the produce of one acre in drying . .		11740 13 0
64 dr. of grass afford of nutritive matter 3 dr. The produce of the space, ditto . . 22.2	15314	1= 957 2 1

This species, like the preceding, is strictly annual; the above is therefore the produce for one year, which, if compared with that of the least productive of the perennial grasses, will be found inferior, and it must consequently be regarded as unworthy of culture.

XXI. *Poa angustifolia.* With. ii. p. 142. Narrow-leaved meadow-grass. Nat. of Britain.

At the time of flowering, the produce from a brown loam is—

Grass, 27 oz. The produce per acre . . .	294030	0=18376 14 0
80 dr. of grass weigh when dry . . 34 dr. The produce of the space, ditto . . $183.2\frac{2}{5}$	124962	12= 7810 2 12
The weight lost by the produce of one acre in drying . .		10566 11 4
64 dr. of grass afford of nutritive matter 5 dr. The produce of the space, ditto . . 33.3	22886	11= 1430 6 11

At the time the seed is ripe the produce is—

Grass, 14 oz. The produce per acre . . .	152460	0=9528 12 0
80 dr. of grass weigh when dry . . 32 dr. The produce of the space, ditto . . $89.2\frac{2}{5}$	60984	0= 3811 8 0
The weight lost by the produce of one acre in drying . .		5717 4 0
64 dr. of grass afford of nutritive matter 5.1 dr. The produce of the space, ditto . . $18.1\frac{1}{2}$	12506	7= 701 6 7
The weight of nutritive matter which is lost by leaving the crop till the seed be ripe, exceeding one-third part of its value		649 0 4

In the early growth of the leaves of this species of *Poa* there is a striking proof that early flowering in grasses is not always connected with the most abundant early produce of leaves. In this respect all the species which have already come under examination are greatly inferior to that now spoken of. Before the middle of April the leaves attain to the length of more than twelve inches, and are soft and succulent; in May, however, when the flower-stalks make their appearance, it is subject to the disease termed rust, which affects the whole plant; the consequence of which is manifest in the great deficiency of produce in the crop at the time the seed is ripe, being one-half less than at the time of the flowering of the grass. Though this disease begins in the straws, the leaves suffer most from its effects, being at the time the seed is ripe completely dried up: the straws, therefore, constitute the principal part of the crop for mowing, and they contain more nutritive matter in proportion than the leaves. This grass is evidently most valuable for permanent pasture, for which, in consequence of its superior, rapid, and early growth, and the disease beginning at the straws, nature seems to have designed it. The grasses which approach nearest to this in respect of early produce of leaves, are the *Poa fertilis*, *Dactylis glomerata*, *Phleum pratense*, *Alopecurus pratensis*, *Avena eliator*, and *Bromus littoreus*, all grasses of a coarser kind.

XXII. *Avena eliator.* Curtis, 112. Engl. Bot. 813.—Holcus avenaceus.

Tall oat-grass. Nat. of Britain.

At the time the seed is ripe, the produce is—

	oz.		or lbs. per acre.		
Grass, 24 oz. The produce per acre . . .	261360	0=	16335	0	0
80 dr. of grass weigh when dry . . 28 dr. The produce of the space, ditto . . 134.1$\frac{3}{5}$	91475	14=	5717	3	14
The weight lost by the produce of one acre in drying . . .			10617	12	2
64 dr. of grass afford of nutritive matter 1 dr. The produce of the space, ditto . . 6	4083	12=	255	3	12

The produce of latter-math is—

Grass 20 oz. The produce per acre . .	217800	0=	13612	8	0
64 dr. of grass afford of nutritive matter 1.1 dr. .	4253	14=	265	13	14
The weight of nutritive matter which is afforded by the crop of the latter-math exceeding that afforded by the grass of the seed crop in proportion nearly as 26 to 25			10	9	2

This grass sends forth flower-straws during the whole season: the latter-math contains nearly an equal number with the flowering crop. It is subject to the rust, but the disease does not make its appearance till after the period of flowering: it affects the whole plant, and at the time the seed is ripe the leaves and straws are withered and dry. This accounts for the superior value of the latter-math over the seed crop, and points out the propriety of taking the crop when the grass is in flower.

XXIII. *Poa eliator.* Curtis, 50.

Tall meadow-grass. Nat. of Scotland.

At the time of flowering, the produce from a rich clayey loam is—

	oz.		or lbs. per acre.		
Grass, 18 oz. The produce per acre . . .	196020	0=	12251	4	0
80 dr. of grass weigh when dry . . 28 dr. The produce of the space, ditto . . 100.3$\frac{2}{10}$	60607	0=	4287	15	0
64 dr. of grass afford of nutritive matter 3.2 The produce of the space, ditto . 15.3	10719	13=	669	15	13
The weight lost by the produce of one acre in drying . . .			3617	15	3

The botanical characters of this grass are almost the same as those of the *Avena eliator*, differing in the want of the awns only. It has the essential character of the *Holci* (Florets male, and hermaphrodite: Calyx husks two valved, with two florets,) and since the *Avena eliator* is now referred to that genus, this may with certainty be considered a variety of it.

XXIV. *Festuca duriuscula.* Engl. Bot. 470. W. B. ii. p. 153.

Hard fescue-grass. Nat. of Britain.

At the time of flowering, the produce from a light sandy loam is—

Grass, 27 oz. The produce per acre . .	294030	0=	18376	14	0
80 dr. of grass weigh when dry . . 36 dr. The produce of the space, ditto . . 194.1$\frac{3}{5}$	132313	8=	8269	9	0
The weight lost by the produce of one acre in drying . . .			10106	4	8
64 dr. of grass afford of nutritive matter 3.2 dr. The produce of the space, ditto . . 23.2$\frac{1}{2}$	16079	12=	1004	15	12

At the time the seed is ripe, the produce is—

Grass, 28 oz. The produce per acre . .	304920	0=	19075	8	0
80 dr. of grass weigh when dry - - 36 dr. The produce of the space, ditto - - 201.2$\frac{2}{5}$	137214	0=	8575	14	0
The weight lost by the produce of one acre in drying - -			10481	10	0
64 dr. of grass afford of nutritive matter 1·2 dr. The produce of the space, ditto - - 10.2 dr.	7146	9=	446	10	9
The weight of nutritive matter which is lost by leaving the crop till the seed be ripe exceeding one-half of its value - - - - -			558	5	3

The proportional value which the grass, at the time the seed is ripe, bears to that at the time of flowering, is as 6 to 14, nearly.

The produce of latter-math is

Grass, 15 oz. The produce per acre - -	163350	0=	10209	6	0
64 dr. of grass afford of nutritive matter 1.1 dr.	3190	4=	199	6	4

The proportional value which the grass of the lattar-math bears to that at the time of flowering, is as 5 to 14, and to that at the time the seed is ripe, 5 to 6.

The above particulars will confirm the favorable opinion which was given of this grass when speaking of the *festuca hordiformis*, and *F. glabra.* Its produce in the spring is not very great, but of the finest quality, and at the time of flowering is considerable. If it be compared with those affecting similar soils, such as *Poa pratensis*, *Festuca ovina*, &c., either considered as a grass for hay, or permanent pasture, it will be found of greater value.

XXV. *Bromus erectus.* Engl. Bot. 471. Host. G. A.

Upright perennial brome-grass. Nat. of Britain.

At the time of flowering, the produce from a rich sandy soil is—

	oz.		or lbs. per acre.		
Grass, 19 oz. The produce per acre - -	206910	0=	12931	14	0
80 dr. of grass weigh when dry - 36 dr. The produce of the space, ditto - $136.3\frac{1}{5}$	93109	8=	5819	5	8
The weight lost by the produce of one acre in drying - - -			7112	8	8
64 dr. of grass afford of nutritive matter 2.3 dr. The produce of the space, ditto - $13.0\frac{1}{4}$	8890	10=	555	10	10

XXVI. *Milium effusum.* Curt. Lond. Engl. Bot. 1106.

Common millet-grass. Nat. of Britain.

At the time of flowering, the produce from a light sandy soil is—

Grass 11 oz. 8 dr. The produce per acre - -	196020	0=	12251	4	0
80 dr. of grass weigh when dry - - 31 dr. The produce of the space, ditto - - $111.2\frac{2}{6}$	75957	12 =	4747	5	12
64 dr. of grass afford of nutritive matter 1.3 The produce of the space, ditto - - $7.3\frac{2}{4}$	5359	14=	334	15	14

This species in its natural state seems confined to woods as its place of growth; but the trial that is here mentioned, confirms the opinion that it will grow and thrive in open exposed situations. It is remarkable for the lightness of the produce, in proportion to its bulk. It produces foliage early in the spring, in considerable abundance; but its nutritive powers appear comparatively little.

XXVII. *Festuca pratensis.* Engl. Bot. 1592. C. Lond.

Meadow fescue-grass. Nat. of Britain.

At the time of flowering, the produce from a bog soil, with coal ashes for manure, is—

Grass, 20 oz. The produce per acre .	217800	0=	13612	8	0
80 dr. of grass weigh when dry . 38 dr. The produce of the space, ditto . 152	103455	8=	6465	15	0
The weight lost by the produce of one acre in drying . .			7146	9	0
64 dr. of grass afford of nutritive matter 4.2 dr. The produce of the space, ditto . 22.2	15314	1=	957	2	1

At the time the seed is ripe, the produce is—

Grass, 28 oz. The produce per acre . .	304920	0=	19057	8	0
80 dr. of grass weigh when dry . 32 dr. The produce of the space, ditto . . $179.0\frac{4}{5}$	121968	0=	7623	0	0
The weight lost by the produce of one acre in drying . .			11434	8	8
64 dr. of grass afford of nutritive matter 1.2 dr. The produce of the space, ditto . 10.2	7146	9=	446	10	9
The weight of nutritive matter which is lost by leaving the crop till the seed be ripe exceeding one half of its value			510	7	8

The value of the grass at the time the seed is ripe, is to that of the grass at the time of flowering, as 6 to 18.

The loss which is sustained by leaving the crop of this grass till the seed be ripe is very great. That it loses more of its weight in drying at this stage of growth, than at the time of flowering, perfectly agrees with the deficiency of nutritive matter in the seed crop, in proportion to that in the flowering crop: the straws being succulent in the former, they constitute the greatest part of the weight; but in the latter they are comparatively withered and dry; consequently the leaves constitute the greatest part of the weight. It may be observed here, that there is a great difference between straws or leaves that have been dried after they were cut in a succulent state, and those which are dried (if I may so express it) by nature while growing. The former retain all their nutritive powers; but the latter, if completely dry, very little, if any.

XXVIII. *Lolium perenne.* Engl. Bot. 315. Flo. Dan. 747.

Perennial rye-grass. Nat. of Britain.

At the time of flowering, the produce from a rich brown loam is—

	oz.		or lbs. per acre.		
Grass, 11 oz. 8 dr. The produce per acre .	125235	0=	7827	3	0
80 dr. of grass weigh when dry . 34 dr The produce of the space, ditto . $78\frac{4}{16}$	53156	13=	3322	4	13
The weight lost by the produce of one acre in drying . . .			4494	14	3
64 dr. of grass afford of nutritive matter 2.2 dr. The produce of the space, ditto . $7.0\frac{3}{4}$	4891	15=	305	11	15

At the time the seed is ripe, the produce is—

Grass, 22 oz. The produce per acre . .	239580	0=	14973	12	0
80 dr. of grass weigh when dry . 24 dr. The produce of the space, ditto . $105.2\frac{2}{3}$	71874	0=	4492	2	0
The weight lost by the produce of one acre in drying . . .			10481	10	0
64 dr. of grass afford of nutritive matter 2.3 dr. The produce of the space, ditto . $15.0\frac{2}{16}$	10294	7=	643	6	7
The weight of nutritive matter which is lost by taking the crop at the time of flowering exceeding nearly one half of its value . . .			337	8	8

The proportional value which the grass at the time of flowering bears to that at the time the seed is ripe is as 10 to 11.

The produce of the latter-math is—

Grass, 5 oz. The produce per acre . .	54450	0=	3403	2	0
64 dr. of grass afford of nutritive matter 1 dr. .	850	12=	53	2	12

The proportional value which the grass of the latter-math bears to that at the time of flowering, is as 4 to 10, and to that at the time the seed is ripe, as 4 to 11.

XXIX. *Poa maritima.* Engl. Bot. 1140.
Sea meadow-grass. Nat. of Britain.

At the time of flowering, the produce from a light brown loam is—

	oz.		or lbs. per acre.		
Grass, 18 oz. The produce per acre . .	196020	0=	12251	4	0
80 dr. of grass weigh when dry . . 32 dr. The produce of the space, ditto . . $115.\frac{1}{5}$	78408	0=	4900	0	0
The weight lost by the produce of one acre in drying . .			7350	4	0
64 dr. of grass afford of nutritive matter 4.2 dr. The produce of the space, ditto . . 20.1	13782	0=	861	6	0

The produce of the latter-math is—

Grass, 18 oz. The produce per acre . .	196020	0=	12251	4	0
64 dr. of grass afford of nutritive matter 1 dr.	3062	13=	191	6	31

The proportional value which the grass of the latter-math bears to that at the time of flowering is as 4 to 18.

XXX. *Cynosurus cristatus.* Engl. Bot. 316. Host. G. A. ii. t. 96.
Crested dog's-tail grass.

At the time of flowering, the produce from the brown loam, with manure, is—

Grass, 9 oz. The produce per acre	98010	0=	6125	10	0
80 dr. of grass weigh when dry . . 24 dr. The produce of the space, ditto . . 43	29403	0=	1837	11	0
The weight lost by the produce of one acre in drying . .			4287	15	0
64 dr. of grass afford of nutritive matter 4.1 dr. The produce of the space, ditto . . $9.2\frac{1}{16}$	6508	7=	406	12	7

At the time the seed is ripe, the produce is—

Grass, 18 oz. The produce per acre . .	196020	0=	12251	4	0
80 dr. of grass weigh when dry . . 32 dr. The produce of the space, ditto . . $115.0\frac{3}{10}$	78408	0=	4900	0	0
The weight lost by the produce of one acre in drying . .			7350	12	0
64 dr. of grass afford of nutritive matter 2.2 dr. The produce of the space, ditto . . 11.1	7657	0=	478	9	0
The weight of nutritive matter which is lost by taking the crop at the time of flowering, exceeding one-sixth of its value			71	12	9

XXXI. *Avena pratensis.* Engl. Bot. 1204. Fl. Dan. 1083.
Meadow oat-grass. Nat. of Britain.

At the time of flowering, the produce from a rich sandy loam is—

	oz.		or lbs. per acre.		
Grass, 10 oz. The produce per acre . . .	108900	0=	6806	4	0
80 dr. of grass weigh when dry . . 22 dr. The produce of the space, ditto . . 44	29947	8=	1871	11	8
The weight lost by the produce of one acre in drying			4934	8	8
64 dr. of grass afford of nutritive matter 2.1 dr. The produce of the space, ditto . . $5.2\frac{1}{2}$	3828	8=	239	4	8

At the time the seed is ripe, the produce is—

Grass, 14 oz. The produce per acre . .	152460	0=	9528	12	0
80 dr. of grass weigh when dry . . 24 dr. The produce of the space, ditto . . $67.0\frac{4}{5}$	45738	0=	2858	10	0
The weight lost by the produce of one acre in drying			6670	2	0
64 dr. of grass afford of nutritive matter 1 dr. The produce of the space, ditto . . 3.2	2382	3=	148	14	3
The weight of nutritive matter which is lost by leaving the crop till the seed be ripe, exceeding one-third part of its value			90	6	0

The proportional value which the crops, at the time the seed is ripe, bear to that at the time of flowering, is as 4 to 9.

XXXII. *Bromus multiflorus.* Engl. Bot. 1884. Host. G. A. i. t. 11.
Many-flowering brome-grass. Nat. of Britain.

At the time of flowering, the produce from a clayey loam is—

Grass, 33 oz. The produce per acre .	359370	0=	22460	10	0
80 dr. of grass weigh when dry . . 44 dr. The produce of the space, ditto . . $290.0\frac{2}{5}$	197653	8=	12353	5	8
The weight lost by the produce of one acre in drying . . .			10107	4	8
64 dr. of grass afford of nutritive matter 5 dr. The produce of the space, ditto . 41.1	28075	12=	1754	11	12

This species is annual, and no valuable properties have as yet been discovered in the seed. It is only noticed on account of its being frequently found in poor grass lands, and sometimes in meadows. It appears from the above particulars to possess nutritive powers equal to some of the best perennial kinds, if taken when in flower; but if left till the seed be ripe (which, from its early growth, is frequently the case), the crop is comparatively of no value, the leaves and straws being then completely dry.

XXXIII. *Festuca loliacea.* Curt. Lond. Engl. Bot. 1821.
Spiked fescue-grass. Nat. of Britain.

At the time of flowering, the produce from a brown rich loam is—

Grass, 24 oz. The produce per acre . .	261360	0=	16335	0	0
80 dr. of grass weigh when dry . 35 dr. The produce of the space, ditto . 168	114345	0=	7146	9	0
The weight lost by the produce of one acre in drying . .			9188	7	0
64 dr. of grass afford of nutritive matter 3 dr. The produce of the space, ditto . 18	12251	4=	765	11	0

At the time the seed is ripe, the produce is—

	oz.		or lbs. per acre.		
Grass, 16 oz. The produce per acre .	174240	0=	10890	0	0
80 dr. of grass weigh when dry . 33 dr. The produce of the space, ditto . $105\frac{3}{5}$	71874	0=	4492	2	0
The weight lost by the produce of one acre in drying			6397	14	0
64 dr. of grass afford of nutritive matter 3.1 dr. The produce of the space, ditto . 13	8848	2=	553	2	0

The latter-math produce is—

Grass, 5 oz. The produce per acre . .	54450	0=	3403	2	0
64 dr. of grass afford of nutritive matter 1.1 dr. .	1063	7=	66	7	7
The weight of nutritive matter which is lost by leaving the crop till the seed be ripe, exceeding one-fourth part of its value			212	11	0

The proportional value which the grass, at the time of flowering, bears to that at the time the seed is ripe, is as 12 to 13; and the value of the latter-math stands in proportion to that of the crop at the time of flowering, as 5 to 12, and to that of the crop taken at the time the seed is ripe, as 5 to 13.

This species of fescue greatly resembles the rye-grass, in habit and place of growth; it has excellencies which make it greatly superior to that grass, for the purposes of either hay or permanent pasture. This species seems to improve in produce in proportion to its age, which is directly the reverse of the *Lolium perenne.*

XXXIV. *Poa cristata.* Host. G. A. ii. t. 75.—Aira Cristata. Engl. Bot. 648.
Crested meadow-grass. Nat. of Britain.

At the time of flowering, the produce from a sandy loam is—

Grass, 16 oz. The produce per acre . .	174240	0=	10890	0	0
80 dr. of grass weigh when dry . . 36 dr. The produce of the space, ditto . . $115\frac{3}{16}$	7848	0=	4900	8	0
The weight lost by the produce of one acre in drying . . .	-	-	5989	8	0
64 dr. of grass afford of nutritive matter 2 dr. The produce of the space, ditto . . 8	5445	0=	340	5	0

The produce of this species, and the nutritive matter that it affords, are equal to those of the *Festuca ovina* at the time the seed is ripe: they equally delight in dry soils. The greater bulk of grass in proportion to the weight, with the comparative coarseness of the foliage, render the *Poa cristata* inferior to the *Festuca ovina.*

XXXV. *Festuca myurus.* Engl. Bot. 1412. Host. G. A. ii. t. 93.
Wall fescue-grass. Nat. of Britain.

At the time of flowering, the produce from a light sandy soil is—

	oz.		or lbs. per acre.		
Grass, 14 oz. The produce per acre . .	152460	0=	9528	12	0
80 dr. of grass weigh when dry . . 24 dr. The produce of the space, ditto . $67\frac{2}{10}$	45738	0=	2858	10	0
The weight lost by the produce of one acre in drying . . .	.	.	6670	2	0
64 dr. of grass afford of nutritive matter 1·2 dr. The produce of the space, ditto . . 5·1	8573	4=	223	5	4

This species is strictly annual; it is likewise subject to the rust; and the above being its whole produce for one year, it ranks as a very inferior grass.

XXXVI. *Aira flexuosa.* Engl. Bot. 1519. Host. G. A. ii. t. 43.
Waved mountain hair-grass. Nat. of Britain.

At the time of flowering, the produce from a heath soil is—

Grass, 12 oz. The produce per acre .	130680	0=	8167	8	0
80 dr. of grass weigh when dry . 31 dr. The produce of the space, ditto . $74\frac{2}{5}$	50638	0=	3164	14	8
The weight lost by the produce of one acre in drying . .			5002	9	8
64 dr. of grass afford of nutritive matter 1.2 dr. The produce of the space, ditto . 4.2	3062	13=	191	6	13

XXXVII. *Hordeum bulbosum.* Hort. Kew. i. p. 179.
Bulbous barley-grass. Nat. of Italy and the Levant. Introduced 1770, by Mons. Richard.

At the time of flowering, the produce from a clayey loam, with manure, is—

Grass, 35 oz. The produce per acre . .	381150	0=	23821	0	0
80 dr. of grass weigh when dry . 93 dr. The produce of the space, ditto . 231	157224	0=	9826	8	6
The weight lost by the produce of one acre in drying . .			13994	7	10
64 dr. of grass afford of nutritive matter 3.2 dr. The produce of the space, ditto . $30.2\frac{2}{4}$	20844	2=	1302	12	2

XXXVIII. *Festuca calamaria.* Engl. Bot. 1005.
Reed-like fescue-grass. Nat. of Britain.

At the time of flowering, the produce from a clayey loam is—

Grass, 80 oz. The produce per acre . .	871200	0=	54450	0	0
80 dr. of grass weigh when dry . . 28 dr. The produce of the space, ditto . . 448	304920	0=	19057	8	0
The weight lost by the produce of one acre in drying			35392	8	0
64 dr. of grass afford of nutritive matter 4.2 dr. The produce of the space, ditto . . 90	61256	4=	3828	8	4

At the time the seed is ripe, the produce is—

Grass, 75 oz. The produce per acre . .	816750	0=	51046	14	0
80 dr. of grass weigh when dry . . 19 dr. The produce of the space, ditto . . 283	193978	2=	12123	10	0

	oz.	or lbs. per acre.
The weight lost by the produce of one acre in drying		38223 1 0
64 dr. of grass afford of nutritive matter 3 dr. The produce of the space, ditto . . 56.1	38285 2=	2392 13 2
The weight of nutritive matter which is lost by leaving the crop till the seed is ripe, being nearly one-third part of its value		1435 11 2

The proportional value which the grass at the time the seed is ripe, bears to that at the time of flowering, is as 12 to 18.

This grass, as has already been remarked, produces a fine early foliage in the spring. The produce is very great, and its nutritive powers are considerable. It appears, from the above particulars, to be best adapted for hay. A very singular disease attacks, and sometimes nearly destroys, the seed of this grass: the cause of this disease seems to be unknown; it is denominated Clavus by some; it appears by the seed swelling to three times its usual size in length and thickness, and the want of the carcle. Dr. Willdenow describes two distinct species of it: 1st, the simple clavus, which is mealy and of a dark color, without any smell or taste; 2dly, the malignant clavus, which is violet blue, or blackish, and internally too has a bluish color, a fœtid smell, and a sharp pungent taste. Bread made from grain affected with this last species is of a bluish color; when eaten, produces cramps and giddiness.

XXXIX. *Bromus littoreus.* Host. G. A. P. vii. t. 8.

Sea-side brome-grass. Nat. of Germany: grows on the banks of the Danube and other rivers.

At the time of flowering, the produce from a clayey loam is—

	oz.	or lbs. per acre.
Grass, 61 oz. The produce per acre . .	664290 0=	41518 2 0
80 dr. of grass weigh when dry . . 41 dr. The produce of the space, ditto . . 500.$\frac{2}{16}$	340448 10=	21278 0 10
The weight lost by the produce of one acre in drying . .		20540 1 6
64 dr. of grass afford of nutritive matter 1.2 dr. The produce of the space, ditto . 22.3½	15567 4=	973 1 4

At the time the seed is ripe, the produce is—

	oz.	or lbs. per acre.
Grass, 56 oz. The produce per acre . .	609840 0=	38115 0 0
80 dr. of grass weigh when dry - - 32 dr. The produce of the space, ditto - - $358\frac{1}{6}$	243936 0=	15246 0 0
The weight lost by the produce of one acre in drying - -		22869 0 0
64 dr. of grass afford of nutritive matter 3·2 dr. The produce of the space, ditto - - 196	33950 0=	2084 6 10
The weight of nutritive matter which is lost by taking the crop at the time of flowering, exceeding one-half of its value - - - -		1111 5 6

The proportional value which the grass, at the time of flowering, bears to that at the time the seed is ripe, is as 6 to 14.

This species greatly resembles the preceding in habit and manner of growth, but is inferior to it in value, which is evident from the deficiency of its produce, and of the nutritive matter afforded by it. The whole plant is likewise coarser, and of greater bulk in proportion to its weight. The seed is affected with the same disease which destroys that of the former species.

XL. *Festuca eliator.* Engl. Bot. 1593. Host. G. A. ii. t. 79.

Tall fescue-grass. Nat. of Britain.

At the time of flowering, the produce from a black rich loam is—

	oz.	or lbs. per acre.
Grass, 75 oz. The produce per acre - - -	816750 0=	51046 14 0
80 dr. of grass weigh when dry - - 28 dr. The produce of the space, ditto - - 420	285362 1=	17866 6 8
The weight which is lost by the produce of one acre in drying -		33180 7 8
64 dr. of grass afford of nutritive matter 5 dr. The produce of the space, ditto - - 93.3	63808 9=	3988 0 9

At the time the seed is ripe the produce is—

	oz.	or lbs. per acre.
Grass 75 oz. The produce per acre - -	816750 0=	51046 4 0
80 dr. of grass weigh when dry . . 28 dr. The produce of the space, ditto . . 420	285862 8=	17866 6 0
The weight lost by the produce of one acre in drying . . .		33180 7 8
64 dr. of grass afford of nutritive matter 3 dr. The produce of the space, ditto . . 56.1	38285 2=	2392 13 2
The weight of nutritive matter which is lost by leaving the crop till the seed be ripe, exceeding one-third part of its value		1595 3 7

The proportional value which the grass, at the time the seed is ripe, bears to that at the time of flowering, is as 12 to 20.

The produce of the latter-math is—

	oz.	or lbs. per acre.
Grass, 23 oz. The produce per acre - -	250470 0=	15654 6 0
64 dr. of grass afford of nutritive matter 4 dr.	15054 6=	978 6 6

The proportional value which the grass of the latter-math bears to that of the crop, is as 16 to 20; and to that at the time the seed is ripe, as 12 to 16 inverse.

This species of fescue is closely allied to the *Festuca pratensis*, from which it differs in little, except that it is larger in every respect. The produce is nearly three times that of the *F. pratensis*, and the nutritive powers of the grass are superior, in direct proportion, as 6 to 8.

XLI. *Nardus stricta.* Engl. Bot. 290. Host. G. A. ii. t. 4.

Upright mat-grass. Nat. of Britain.

At the time the seed is ripe, the produce is—

	oz.	or lbs. per acre.
Grass, 9 oz. The produce per acre . .	98010 0=	6125 10 0

	oz.		or lbs. per acre.		
80 dr. of grass weigh when dry . . 32 dr. The produce of the space, ditto . $57.2\frac{2}{5}$	39204	0=	2450	4	0
The weight lost by the produce of one acre in drying . . .			3675	6	0
64 dr. of grass afford of nutritive matter 2.1 dr. The produce of the space, ditto . $5.0\frac{1}{5}$	3445	10=	215	5	10

XLII. *Triticum, Sp.*
Wheat-grass.

At the time of flowering, the produce from a rich randy loam is—

Grass, 18 oz. The produce per acre . .	196020	0=	12251	4	0
80 dr. of grass weigh when dry . . 32 dr. The produce of the space, ditto . . $115\frac{1}{5}$	78408	0=	4900	8	0
The weight lost by the produce of one acre in drying . . .			7350	12	0
64 dr. of grass afford of nutritive matter 2.2 dr. The produce of the space, ditto . 11.1	7657	0=	478	9	0

XLIII. *Festuca fluitans.* Curt. Lond. Engl. Bot. 1520. Poa fluitans.
Floating fescue-grass. Nat. of Britain.

At the time of flowering, the produce from a strong tenacious clay is—

Grass, 20 oz. The produce per acre . .	217800	0=	13612	8	0
80 dr. of grass weigh when dry . . 24 dr. The produce of the space, ditto . . 96	65340	0=	4083	12	0
The weight lost by the produce of one acre in drying . . .			9528	12	0
64 dr. of grass afford of nutritive matter . 1.3 dr. The produce of the space, ditto . . 8.3	5955	0=	372	3	7

The above produce was taken from grass that had occupied the ground for four years, during which time it had increased every year; it therefore appears contrary to what some have supposed to be capable of being cultivated in perennial pastures.

XLIV. *Holcus lanatus.* Curt. Lond. Fl. Dan. 1811.
Meadow soft grass. Yorkshire grass. Nat. of Britain.

At the time of flowering, the produce from a strong clayey loam is—

Grass, 28 oz. The produce per acre . .	304920	0=	19057	8	0
80 dr. of grass weigh when dry . . 26 dr. The produce of the space, ditto . $157.2\frac{2}{5}$	106585	14=	6661	9	14
The weight lost by the produce of one acre in drying . . .			12395	14	2
64 dr. of grass afford of nutritive matter . 4 dr. The produce of the space, ditto . . 28	19057	8=	1191	1	8

At the time the seed is ripe, the produce is—

Grass, 28 oz. The produce per acre . . .	304920	0=	19057	8	0

	oz.		or lbs. per acre.		
80 dr. of grass weigh when dry . . . 16 dr. The produce of the space, ditto . . $89.2\frac{2}{5}$	60984	0=	3811	8	0
The weight lost by the produce of one acre in drying . .			15246	0	0
64 dr. of grass afford of nutritive matter 2.3 dr. The produce of the space, ditto . . 19.1	13102	0=	818	14	0
The weight of nutritive matter which is lost by leaving the crop till the seed is ripe, exceeding one-third part of its value . . .			372	3	8

The proportional value which the grass, at the time the seed is ripe, bears to that at the time of flowering, is as 11 to 12.

XLV. *Festuca dumetorum.* Flor. Dan. 700.
Pubescent fescue-grass. Nat. of Britain.

At the time of flowering, the produce from a black sandy loam is—

Grass, 16 oz. The produce per acre . . .	174240	0=	10890	0	0
80 dr. of grass weigh when dry . . 40 dr. The produce of the space, ditto . . 128	87120	0=	5445	0	0
The weight lost by the produce of one acre in drying . .			5445	0	0
64 dr. of grass afford of nutritive matter 1 dr. The produce of the space, ditto . . 4	2722	8=	170	2	8

XLVI. *Poa fertilis.* Host. G. A.
Fertile meadow-grass. Nat. of Germany.

At the time of flowering, the produce from a clayey loam is—

Grass, 22 oz. The produce per acre . . .	239580	0=	14973	12	0
80 dr. of grass weigh when dry . . 42 dr. The produce of the space, ditto . . $184\frac{1}{5}$	125779	8=	7861	3	8
The weight lost by the produce of one acre in drying . .			7111	8	8
64 dr. of grass afford of nutritive matter 4.2 dr. The produce of the space, ditto . 24.3	16845	7=	1052	13	7

If the nutritive powers and produce of this species be compared with any other of the same family, or such as resemble it in habit and the soil which it affects, a superiority will be found, which ranks this as one of the most valuable grasses; next to the *Poa angustifolia*, it produces the greatest abundance of early foliage, of the best quality, which fully compensates for the comparative lateness of flowering.

XLVII. *Arundo colorata.* Hort. Kew. i. p. 174. Engl. Bot. 402. Phalaris arundinacea.
Striped-leaved reed-grass. Nat. of Britain.

At the time of flowering, the produce from a black sandy loam is—

Grass, 40 oz. The produce per acre . .	435600	0=	27225	0	0

	oz.	or lbs. per acre.
80 dr. of grass weigh when dry . . 36 dr. The produce of the space, ditto . . 288	196020	0=12251 4 0
64 dr. of grass afford of nutritive matter 4 dr. The produce of the space, ditto . 40	27225	0= 1701 9 0

The strong nutritive powers which this grass possesses recommend it to the notice of occupiers of strong clayey lands which cannot be drained. Its produce is great, and the foliage will not be denominated coarse, if compared with those which afford a produce equal in quantity.

XLVIII. *Trifolium pratense.* W. Bot. iii. p. 137. Broad-leaved cultivated clover. Nat. of Britain.

At the time the seed is ripe, the produce from a rich clayey loam is—

Grass, 72 oz. The produce per acre . .	784080	0=49005 0 0
80 dr. of grass weigh when dry . 20 dr. The produce of the space, ditto . 288	196020	0=12251 0 0
The weight lost by the produce of one acre in drying . .		3675 4 0
64 dr. of grass afford of nutritive matter 2.2 dr. The produce of the space, ditto . 45	30628	2= 1914 4 2

If the weight which is lost by the produce of this species of clover, in drying, be compared with that of many of the natural grasses, its inferior value for the purpose of hay, compared to its value for green food or pasture, will appear; for it is certain that the difficulty of making good hay increases in proportion with the quantity of superfluous moisture which the grass may contain. Its value for green food, or pasture, may further be seen by comparing its nutritive powers with those manifested by other plants generally esteemed best for this purpose.

Trifolium pratense (as above) affords of nutritive matter - - - - 2.2 dr.

XLIX. *Trifolium repens* (white clover) from an equal quantity of grass 2.0 dr.

L. Ditto, variety, with brown leaves, ditto 2.2

The grass of the *T. pratense*, therefore, exceeds in value that of the *T. repens* by a proportion as 8 to 10; but it is of equal proportional value with the brown variety.

LI. *Burnet* (Poterium sanguisorba) affords of nutritive matter - - - - - 2.2 dr.

LII. *Brunias orientalis* (a newly introduced plant) ditto - - - 2.2

The proportional value of these two last, and of the *T. pratense*, and the brown-leaved variety of *T. repens*, are equal: they exceed the *T. repens* as 8 to 10.

The comparative produce of these four last-mentioned species, per acre, has not been ascertained.

LIII. *Trifolium macrorhizum.* Log-rooted clover. Nat. of Hungary.

At the time the seed is ripe, the produce from a rich clayey loam is—

	oz.	or lbs. per acre.
Grass, 144 oz. The produce per acre .	1568160	0=98010 0 0
80 dr. of grass weigh when dry . . 34 dr. The produce of the space, ditto . . 979 1/5	666168	0=41654 4 0
The weight lost by the produce of one acre in drying . .		56355 12 0
64 dr. of grass afford of nutritive matter 2.3 dr. The produce of the space, ditto . 99	67381	14= 4211 5 14

The root of this species of clover is biennial; it penetrates to a great depth in the ground, and is in consequence little affected by the extremes of wet or dry weather. It requires good shelter, and a deep soil. The produce, when compared to that of others that are allied to it in habit and place of growth, proves greatly superior. The following particulars, some of which refer to results stated in the next two pages, will make this manifest:—

		lbs.
Trifolium pratense, Broad-leaved clover	Produces per acre, Grass	49005
	Ditto, Hay	12251
	Affords, do., of nutritive matter	1914
Medicago sativa, Lucern. From a soil of the like nature	Produces per acre, Grass	70785
	Ditto, Hay	28314
	Affords of nutritive matter	1659
Hedysarum onobrychis, Saintfoin	Produces per acre, Grass	8848
	Ditto, Hay	3536
	Affords of nutritive matter	314

The weight of nutritive matter afforded by the produce of the *T. macrorhizum*, exceeding that of the *T. pratense* in proportion nearly as 7 to 15 . . . lbs. 2297

The proportional value of the grass of *T. pratense*, to that of *T. macrorhizum*, is 10 to 11.

The weight of nutritive matter afforded by the *T. macrorhizum*, exceeding that of the *Medicago sativa* in proportion nearly as 13 to 33 . . . 2552

The proportional value of the grass is as 11 to 6.

The weight of nutritive matter which is afforded by the produce of the *T. macrorhizum*, exceeding that of the *Hedysarum onobrychis* in proportion as 5 to 67 3897

The proportional value of the grass, like that of the *T. pratense*, is as 11 to 10.

The produce of each of the above-mentioned species was taken from a similar soil, and in the same situation; the conclusions must therefore be considered positive with respect to such soils only. It is evident that more than twice the quantity of nutritive matter is afforded by the produce of one acre of the *T. macrorhizum*, than from the produce of an equal space covered by the *T. pratense.* Its short duration in the soil (for if sown early in the autumn, on a rich light soil, it is only an annual plant) renders it fit only for green-food or hay; this in some measure lessens its value when compared with the *T. pratense.* It possesses the essential property of affording abundance of good seed; and if the ground be kept clear of weeds, it sows itself, vegetates, and grows rapidly, without covering-in, or any operation whatever. For four years it has propagated itself in this manner, on the space of ground which it now occupies, and from which this statement of its comparative value is made. The produce of lucern in grass comes nearer to this species in quantity, but is greatly deficient in nutritive matter, as much as 13 to 33. The long continuance of lucern in the soil is therefore the only merit which it possesses above the two last-mentioned species; and when that is the object of the cultivator, it will of necessity have the preference.

The value of the grass of saintfoin is equal to that of the *T. pratense;* and proportionally less than that of the *Trifolium macrorhizum*, as 10 to 11. The quantity of grass is very small, and on soils of the nature above described it is doubtless inferior. However, from the superior value of the grass, on dry hilly situations, or chalky soils, it may in such situations possibly be their superior in every respect.

LIV. *Medicago Sativa.* Wither. B. iii. p. 643. Lucern. Nat. of Brit.

At the time the seed is ripe, the produce from a rich clayey loam is—

	oz.	or lbs. per acre.
Grass, 104 oz. The produce per acre . .	1132560 0	=70785 0 0
80 dr. of grass weigh when dry . 32 dr. The produce of the space, ditto . 665·2⅖	453024 0	=28314 0 0
The weight lost by the produce of one acre in drying . .		42471 0 0
64 dr. of grass afford of nutritive matter 1.2 dr. The produce of the space, ditto . . 39	26544 6	= 7659 0 6

LV. *Hedysarum onobrychis.* Wither. iii. p. 628. Saintfoin. Nat. of Britain.

At the time the seed is ripe, the produce from a rich clayey loam is—

	oz.	or lbs. per acre.
Grass, 13 oz. The produce per acre	141570 0	= 8848 2 0
80 dr. of grass weigh when dry . 32 dr. The produce of the space, ditto . 83⅕	56628 0	= 3539 4 0
The weight lost by the produce of one acre in drying . . .		5308 14 0
64 dr. of grass afford of nutritive matter 2.2 dr. The produce of the space, ditto . 8.0½	5530 1	= 345 10 1

LVI. *Hordeum pratense.* Engl. Bot. 409. Host. G. A. i. t. 33. Meadow barley-grass. Nat. of Britain.

At the time of flowering, the produce from a brown loam, with manure, is—

	oz.	or lbs. per acre.
Grass, 12 oz. The produce per acre . .	130680 0	= 8167 8 0
80 dr. of grass weigh when dry . . 32 dr. The produce of the space, ditto . . 67.1	52272 0	= 3267 0 0
The weight lost by the produce of one acre in drying . .		4900 8 0
64 dr. of grass afford of nutritive matter 3.3 dr. The produce of the space, ditto . 11.1	7657 0	= 478 9 0

LVII. *Poa compressa.* Engl. Bot. 365. Flat-stalked meadow-grass. Nat. of Brit.

At the time of flowering, the produce from a gravelly soil, with manure, is—

	oz.	or lbs. per acre.
Grass, 5 oz. The produce per acre . . .	54450 0	= 3403 2 0
80 dr. of grass weigh when dry . . 34 dr. The produce of the space, ditto . . 34	23141 4	= 1446 5 4
The weight lost by the produce of one acre in drying . . .		1956 12 12
64 dr. of grass afford of nutritive matter 5 dr. The produce of the space, ditto . . 6.1	4253 14	= 265 13 14

The specific characters of this species are much the same as those of the *Poa fertilis*, differing in the compressed figure of the straws, and creeping root only. If the produce was of magnitude, it would be one of the most valuable grasses; for it produces foliage early in the spring, and possesses strong nutritive powers.

LVIII. *Poa aquatica.* Curt. Lond. Engl. Bot. 1315. Reed meadow-grass. Nat. of Britain.

At the time of flowering, the produce from a strong tenacious clay is—

	oz.	or lbs. per acre.
Grass, 186 oz. The produce per acre . . .	2025540	= 126596 4 0
80 dr. of grass weigh when dry . . 48 dr. The produce of the space, ditto . . 1785.2 2/16	1215324	= 75957 12 0
The weight lost by the produce of one acre in drying . .		50638 8 0
64 dr. of grass afford of nutritive matter 2.2 dr. The produce of the space, ditto . . 116.1	79122	= 4945 2 10

LIX. *Aira aquatica.* Curt. Lond. Engl. Bot. 1557. Water hair-grass. Nat. of Britain.

At the time of flowering, the produce from water is—

	oz.	or lbs. per acre.
Grass, 16 oz. The produce per acre . . .	174240 0	= 10890 0 0
80 dr. of grass weigh when dry . . 24 dr. The produce of the space, ditto . . 76.3 1/16	52272 0	= 3267 0 0
The weight lost by the produce of one acre in drying . . .		7623 0 0
64 dr. of grass afford of nutritive matter 2.1 dr. The produce of the space, ditto - . 9	6122 10	= 382 13 10

LX. *Bromus cristatus.* Triticum cristatum, H. G. A. 2. t. 24. Secale prostratum. Jacquin. Nat. of Germany.

At the time of flowering, the produce from a clayey loam is—

	oz.	or lbs. per acre.
Grass, 13 oz. The produce per acre . . .	141570 0	= 8848 0 0
80 dr. of grass weigh when dry . . . 32 dr. The produce of the space, ditto . . 83.1	56628 0	= 3539 4 0
The weight lost by the produce of one acre in drying . . .		5308 14 0
64 dr. of grass afford of nutritive matter 2.2 dr. The produce of the space, ditto . . 8.0 2/16	5530 1	= 345 10 0

LXI. *Elymus Sibiricus.* Hort. K. i. p. 176. Cult. 1758, by Mr. P. Millar.

Siberian lyme-grass. Nat. of Siberia.

At the time of flowering, the produce from a sandy loam, with manure, is—

	oz.	or lbs. per acre.
Grass, 24 oz. The produce per acre . .	261360 0	=16335 0 0
80 dr. of grass weigh when dry . . 28 dr. The produce of the space, ditto . 1341.$\frac{3}{5}$	91476 0	= 5717 4 0
The weight lost by the produce of one acre in drying . . .		10617 12 0
64 dr. of grass afford of nutritive matter 2.1 dr. The produce of the space, ditto . . 13.2	9188 7	= 511 7 0

LXII. *Aira cæspitosa.* Host. G. A. ii. t. 42. Engl. Bot. 1557.

Turfy hair-grass. Nat. of Britain.

At the time the seed is ripe, the produce from a strong tenacious clay is—

	oz.	or lbs. per acre.
Grass, 15 oz. The produce per acre .	163350 6	=10209 6 0
80 dr. of grass weigh when dry . 26 dr. The produce of the space, ditto . 135$\frac{1}{5}$	53088 12	= 3318 0 12
The weight lost by the produce of one acre in drying . .		6891 5 4
64 dr. of grass afford of nutritive matter 2 dr. The produce of the space, ditto . 7.2	5104 11	= 319 0 1

LXIII. *Hordeum murinum.* Curt. Lond. Engl. Bot. 1971.

Wall barley-grass. Way Bennet. Nat. of Britain.

At the time of flowering, the produce from a clayey loam is—

	oz.	or lbs. per acre.
Grass, 18 oz. The produce per acre . .	196020 0	= 12251 4 0
80 dr. of grass weigh when dry - - 28 dr. The produce of the space, ditto - - 100.3$\frac{1}{5}$	68607 0	= 4287 15 0
The weight lost by the produce of one acre in drying . . .		7963 5 0
64 dr. of grass afford of nutritive matter 3 dr. The produce of the space, ditto . . 3.3$\frac{3}{16}$	2679 15	= 167 7 15

LXIV. *Avena flavescens.* Curt. Lond. Engl. Bot. 952.

Yellow oat-grass. Nat. of Britain.

At the time of flowering, the produce from a clayey loam is—

	oz.	or lbs. per acre.
Grass 12 oz. The produce per acre - . -	130680 0	= 8167 8 0
80 dr. of grass weigh when dry . 28 dr. The produce of the space, ditto . 67.1	45738 0	= 2858 10 0
The weight lost by the produce of one acre in drying . . .		5308 14 0
64 dr. of grass afford of nutritive matter 3.3 dr. The produce of the space, ditto . . 11.1	7657 0	= 478 9 0

At the time the seed is ripe, the produce is—

	oz.	or lbs. per acre.
Grass, 18 oz. The produce per acre . .	196020 0	=12251 4 0
80 dr. of grass weigh when dry - 32 dr. The produce of the space, ditto - 115.0$\frac{1}{5}$	78408 0	= 4900 8 0
The weight lost by the produce of one acre in drying		7350 12 0
64 dr. of grass afford of nutritive matter 2.1 dr. The produce of the space, ditto . . 10.0$\frac{1}{2}$	6891 5	= 430 11 5
The weight of nutritive matter which is lost if the crop be left till the seed be ripe, exceeding one-tenth part of its value . . .		47 13 11

The proportional value which the grass at the time the seed is ripe, bears to that at the time of flowering, is as 9 to 15.

The produce of latter-math is—

	oz.	or lbs. per acre.
Grass, 6 oz. The produce per acre . .	65340 0	= 4083 12 0
64 dr. of grass afford of nutritive matter 1.1 dr.	1276 2	= 79 12 2

The proportional value which the grass of the latter-math bears to that at the time of flowering, is as 5 to 15; and to that at the time the seed is ripe, as 5 to 9.

This species is pretty generally cultivated in many parts of this kingdom; and it appears from the above details to be a valuable grass, though inferior to many others.

LXV. *Bromus sterilis.* Engl. Bot. 1030. Host. G. A. i. t. 16.

Barren brome-grass. Nat. of Britain.

At the time of flowering, the produce from a sandy soil is—

	oz.	or lbs. per acre.
Grass, 44 oz. The produce per acre . .	479160 0	=29947 8 0
80 dr. of grass weigh when dry . . 45 dr. The produce of the space ditto . . 396	269527 8	=16845 7 8
The weight lost by the produce of one acre in drying . .		13102 0 8
64 dr. of grass afford of nutritive matter 5 dr. The produce of the space, ditto . . 55	37434 6	= 2339 10 0

64 dr. of the flowers afford of nutritive matter 2.2 dr. The nutritive powers of the straws and leaves are, therefore, more than twice as great as those of the flowers. This species, being strictly annual, is of comparatively little value. The above particulars show that it has very considerable nutritive powers, more than its name would imply, if taken at the time of flowering; but if left till the seed be ripe, it is like all other annuals, comparatively of no value.

LXVI. *Holcus mollis.* Curt. Lond. Wither. B. ii. p. 134.

Creeping soft-grass. Nat. of Britain.

At the time of flowering, the produce from a sandy soil is—

	oz.	or lbs. per acre.
Grass, 50 oz. The produce per acre . .	544500 0	=34031 4 0
80 dr. of grass weigh when dry . . 32 dr. The produce of the space, ditto . . 320	217800 0	=13612 8 0

oz. or lbs. per acre.

The weight lost by the produce of one acre in drying . . . 20418 12 0

64 dr. of grass afford of nutritive matter 4.2 dr.
The produce of the space, ditto - - 56.1 } 38285 2= 2392 13 2

At the time the seed is ripe, the produce is—

Grass, 31 oz. The produce per acre - - 337590 0=21099 6 0

80 dr. of grass weigh when dry - - 32 dr.
The produce of the space, ditto - - $198.1\frac{3}{5}$ } 135036 0= 8439 12 0

The weight lost by the produce of one acre in drying - - - 12659 10 0

64 dr. of grass afford of nutritive matter 3.2 dr.
The produce of the space, ditto - - $27.0\frac{2}{5}$ } 18461 15= 1153 13 15

The weight of nutritive matter which is lost by leaving the crop till the seed be ripe, being nearly one-half of its value - - - - 1238 15 3

64 dr. of the roots afford of nutritive matter 5.2 dr.

The proportional value which the grass at the time the seed is ripe, bears to that at the time of flowering, is as 14 to 18.

The above details prove this grass to have merits which, if compared with those of other species, rank it with some of the best grasses. The small loss of weight which it sustains in drying might be expected from the nature of the substance of the grass; and the loss of weight at each period is equal. The grass affords the greatest quantity of nutritive matter when in flower, which makes it rank as one of those best adapted for hay.

LXVII. *Poa fertilis.* Var. B. Host. G. A. The species.
Fertile meadow-grass. Variety 1. Nat. of Germany.

At the time of flowering, the produce from a brown sandy loam is—

Grass, 23 oz. The produce per acre - - 250470 0=15654 6 0

80 dr. of grass weigh when dry - - 34 dr.
The produce of the space, ditto - - $156\frac{3}{5}$ } 106448 0= 6653 8 0

The weight lost by the produce of one acre in drying - - - - 9000 14 0

64 dr. of grass afford of nutritive matter 3 dr.
The produce of the space, ditto - - 17.1 } 11740 12= 733 12 12

At the time the seed is ripe, the produce is—

Grass, 22 oz. The produce per acre . . 239580 0= 14978 12 0

80 dr. of grass weigh when dry . . 44 dr.
The produce of the space, ditto . 193.2 } 131769 0= 8235 9 0

The weight lost by the produce of one acre in drying . . 6738 3 0

64 dr. of grass afford of nutritive matter 5 dr.
The produce of the space, ditto . 27.2 } 18717 3= 1169 13 3

The weight of nutritive matter which is lost by taking the crop at the time of flowering, exceeding one-third part of its value, is . . . 436 1 3

The proportional value which the grass at the time of flowering bears to that at the time the seed is ripe, is as 12 to 20.

The produce of latter-math is—

oz. or lbs. per acre.

Grass, 7 oz. The produce per acre . . 76230 0= 4764 6 0

64 dr. of grass afford of nutritive matter 1.2 dr. 1786 10= 111 10 10

The proportional value which the grass of the latter-math bears to that at the time of flowering, is as 6 to 12; and to that at the time the seed is ripe, as 6 to 20.

LXVIII. *Cynosurus erucæformis.* Beckmannia erucæformis. Host. G. A. iii. t. 6.
Linear-spiked dog's-tail grass. Nat. of Germany.

At the time the seed is ripe, the produce is—

Grass, 18 oz. The produce per acre - - 196020 0=12251 4 0

80 dr. of grass weigh when dry - 36 dr.
The produce of the space, ditto - $129.2\frac{2}{5}$ } 88209 0= 5513 1 0

The weight lost by the produce of one acre in drying - - - 6738 3 0

64 dr. of grass afford of nutritive matter 3.1 dr.
The produce of the space, ditto - $14.2\frac{3}{4}$ } 9954 2= 622 2 2

LXIX. *Phleum nodosum.* With. B. ii. p. 118.
Bulbous-stalked cat's-tail grass. Nat. of Britain.

At the time of flowering, the produce from a clayey loam is—

Grass, 18 oz. The produce per acre - - 196020 0=12251 4 0

80 dr. of grass weigh when dry - - 38 dr.
The produce of the space, ditto - - $136\frac{1}{5}$ } 93109 8= 5819 5 8

The weight lost by the produce of one acre in drying - - - 6431 14 0

64 dr. of grass afford of nutritive matter 2.2 dr.
The produce of the space, ditto - - 11.1 } 7657 0= 478 9 0

This grass is inferior in many respects to the *Phleum pratense.* It is sparingly found in meadows. From the number of bulbs which grow out of the straws, a greater portion of nutritive matter might have been expected. This seems to prove that these bulbs do not form so valuable a part of the plant as the joints, which are so conspicuous in the *Phleum pratense,* the nutritive powers of which exceed those of the *P. nodosum,* as 8 to 28.

LXX. *Phleum pratense.* Wither. ii. p. 117.
Meadow cat's-tail grass. Nat. of Britain.

At the time of flowering, the produce from a clayey loam is—

Grass, 60 oz. The produce per acre - - 653400 0= 40837 8 0

80 dr. of grass weigh when dry - 34 dr.
The produce of the space, ditto - 408 } 277695 0= 17355 15 0

The weight lost by the produce of one acre in drying - - 23481 9 0 oz. or lbs. per acre.

65 dr. of grass afford of nutritive matter 2 2 dr. The produce of the space, ditto - 37.2 — 25523 7= 1595 3 0

The weight of nutritive matter which is lost by leaving the crop till the seed be ripe, exceeding one-half of its value — 2073 11 0

At the time the seed is ripe the produce is—

Grass, 60 oz. The produce per acre - - — 653400 0=40837 8 0

80 dr. of grass weigh when dry - 38 dr. The produce of the space, ditto - 456 — 310365 0=19397 13 0

The weight lost by the produce of one acre in drying - - — 21439 11 0

64 dr. of grass afford of nutritive matter 5.3 dr. The produce of the space, ditto - - 86.1 — 58703 14= 3668 15 14

The latter-math produce is—

Grass 14 oz. The produce per acre - - — 152460 0= 9528 12 0

64 dr. of grass afford of nutritive matter 2 dr. — 4764 6= 297 12 6

64 dr. of the straws afford of nutritive matter 7 dr. The nutritive powers of the straws simply, therefore, exceed those of the leaves, in proportion as 28 to 8; and the grass at the time of flowering, to that at the time the seed is ripe, as 10 to 23; and the latter-math, to the grass of the flowering crop, as 8 to 10.

The comparative merits of this grass will appear from the above particulars to be very great; to which may be added the abundance of fine foliage that it produces early in the spring. In this respect it is inferior to the *Poa fertilis* and *Poa angustifolia* only. The value of the straws at the time the seed is ripe exceeds that of the grass at the time of flowering, as 28 to 10; a circumstance which increases its value above many others; for, by this property, its valuable early foliage may be cropped to an advanced period of the season without injury to the crop of hay, which in other grasses which send forth their flowering straws early in the season would cause a loss of nearly one-half of the value of the crop, as is clearly proved by former examples; and this property of the straws makes the plant peculiarly valuable for the purpose of hay.

LXXI. *Phleum pratense.* Var. minor. Wither. B. ii. p. 118. Var. 1.
Meadow cat's-tail grass. Var. Smaller. Nat. of Britain.

At the time of ripening the seed, the produce from a clayey loam is—

Grass, 40 oz. The produce per acre - - — 435600 0=27225 0 0

80 dr. of grass weigh when dry - - - 34 dr. The produce of the space, ditto - - 272 — 185130 0=11570 10 0

The weight lost by the produce of one acre in drying - - - - - — 15654 6 0

64 dr. of grass afford of nutritive matter 2.3 dr. The produce of the space, ditto - 272 — 1817 3= 1169 13 3

Awnless brome-grass. Nat. of Germany. Introduced by Mr. Hunneman in 1794.

At the time the seed is ripe, the produce from a black sandy soil is—

Grass, 18 oz. The produce per acre - - — 196020 0=12251 4 0

80 dr. of grass weigh when dry - - 35 dr. The produce of the space, ditto - - 126 — 85758 12= 5359 14 12

The weight lost by the produce of one acre in drying - - - - - — 6891 5 4

64 dr. of grass afford of nutritive matter 4.1 dr. The produce of the space, ditto - - 19.0⅗ — 13016 15= 813 8 15

The produce of the latter-math is—

Grass 13 oz. The produce per acre - - - — 141570 0= 8848 2 0

64 dr. of grass afford of nutritive matter 1.1 dr. - — 2765 0= 172 13 0

LXXV. *Agrostis vulgaris.* Wither. Bot. ii. 132. Hud. A. capilaris; Dr. Smith, A. arenaria.
Fine bent-grass. Nat. of Britain.

At the time the seed is ripe, the produce from a sandy soil is—

Grass, 14 oz. The produce per acre - - - — 152460 0= 9528 12 0

80 dr. of grass weigh when dry 40 dr. The produce of the space, ditto - - 112 — 76230 0 = 4764 6 0

	oz.	or lbs. per acre.
The weight lost by the produce of one acre in drying - - - - -		4764 6 0
64 dr. of grass afford of nutritive matter $1.2\frac{3}{16}$; The produce of the space, ditto - - $5.1\frac{1}{16}$	4019 15=	251 3 15

This is one of the most common of the bents, likewise the earliest; in these respects it is superior to all others of the same family, but inferior to several of them in produce and the quantity of nutritive matter it affords. As the species of this family are generally rejected by the cultivator on account of the lateness of their flowering, and this circumstance, as has already been observed, does not always imply a proportional lateness of foliage, their comparative merits in this respect may be better seen by bringing them into one view, as to the value of their early foliage.

	The apparent difference of time.	Their nutritive powers.
Agrostis vulgaris	Middle of April -	$1.2\frac{3}{4}$
palustris	One week later -	2.3
stolonifera	Two ditto - -	3.2

LXXVIII. *Agrostis stolonifera.* Engl. Bot. 1532. Wither. Bot. ii. 181. (Fiorin, Dr. Richardson.)

Creeping bent. Nat. of Britain.

At the time of flowering, the produce from a bog soil is—

Grass, 26 oz. The produce per acre - - -	283140 0=	17696 4 0
80 dr. of grass weigh when dry - - 35 dr.; The produce of the space, ditto - - 182	123873 12=	7742 1 12
The weight lost by the produce of one acre - - - - - - -		9732 15 0
64 dr. of grass afford of nutritive matter 3.2 dr.; The produce of the space, ditto - - 22.3	15484 3=	967 12 0

At the time the seed is ripe, the produce is—

Grass, 28 oz. The produce per acre - - -	304920 0=	19057 8 0
80 dr. of grass weigh when dry - - 36 dr.; The produce of the space, ditto - - $201.2\frac{2}{5}$	137214 0=	8575 14 0
The weight lost by the produce of one acre in drying - - - - -		10481 10 0
64 dr. of grass afford of nutritive matter 3.2 dr.; The produce of the space, ditto - 24.2	16675 0=	1042 3 5
The weight of nutritive matter which is lost by taking the crop at the time of flowering, being nearly one-fourteenth of its value - - - - -		74 7 2

LXXIX. *Agrostis stolonifera.* Var. angustifolia. Creeping bent, with narrow leaves. Nat. of Britain.

At the time the seed is ripe, the produce from a bog soil is—

Grass, 26 oz. The produce per acre - -	261360 0=	16335 0 0
80 dr. of grass weigh when dry - - 36 dr.; The produce of the space, ditto - - $172.3\frac{1}{5}$	117612 0=	7350 12 0
The weight lost by the produce of one acre in drying - - - -		8984 4 0
64 dr. of grass afford of nutritive matter 3 dr.; The produce of the space, ditto - - 18	12251 4=	765 11 4
The weight of nutritive matter afforded by the produce of one acre of the *Agrostis stolonifera* exceeding that of the variety in proportion, as 6 to 8 -		276 8 1

The above details will assist the farmer in deciding on the comparative value of this grass. From a careful examination it will doubtless appear to possess merits well worthy of attention, though perhaps not so great as has been supposed, if the natural place of its growth and habits be impartially taken into the account. From the couchant nature of this grass, it is denominated couch-grass by practical men; and from the length of time that it retains the vital power, after being taken out of the soil, is called squitch, quick, full of life, &c.

LXXX. *Agrostis canina.* Engl. Bot. 1856.
Brown-bent. Nat. of Britain.

At the time of flowering, the produce from a brown sandy loam is—

	oz.		or lbs. per acre.		
Grass, 9 oz. The produce per acre - -	98010	0=	6125	10	0
80 dr. of grass weigh when dry - - 34 dr. The produce of the space, ditto - - $63\frac{1}{5}$	43013	0=	2588	5	0
The weight lost by the produce of one acre in drying - - - - -			3437	5	0
64 dr. of grass afford of nutritive matter 2.2 dr. The produce of the space, ditto - - $52.1\frac{1}{2}$	3828	8=	239	4	8

LXXXI. *Agrostis canina.* Var. muticæ.
Awnless brown bent. Nat. of Britain.

At the time the seed is ripe, the produce from a sandy soil is—

Grass, 21 oz. The produce per acre - -	228690	0=	14293	2	0
80 dr. of grass weigh when dry - 24 dr. The produce of the space, ditto - $100.3\frac{1}{5}$	68607	0=	4287	15	0
The weight lost by the produce of one acre in drying - -			10005	3	0
64 dr. of grass afford of nutritive matter 1.3 dr. The produce of the space, ditto - $9.0\frac{3}{4}$	6253	3=	390	13	3
The weight of nutritive matter which the produce of one acre of the awnless variety exceeds that of the last mentioned species - -			151	8	11

LXXXII. *Agrostis stricta.* Curt. A. rubra.
Upright bent-grass. Nat. of Britain.

At the time the seed is ripe, the produce from a bog soil is—

Grass, 11 oz. The produce per acre - - -	119790	0=	7486	14	0
80 dr. of grass weigh when dry - 29 dr. The produce of the space, ditto - $63\frac{1}{5}$	43423	14=	2713	15	0
The weight lost by the produce of one acre in drying - - -			4772	15	0
64 dr. of grass afford of nutritive matter 1.2 dr. The produce of the space, ditto - - $4.0\frac{5}{10}$	2807	9=	175	7	5

LXXXIII. *Agrostis nivea.*
Snowy bent-grass. Nat. of Britain.

At the time the seed is ripe, the produce from a sandy soil is—

	oz.		or lbs. per acre.		
Grass, 7 oz. The produce per acre - - -	76230	0=	4764	6	0
80 dr. of grass weigh when dry - - 22 dr. The produce of the space, ditto - - $30.3\frac{1}{5}$	20963	4=	1310	3	0
The weight lost by the produce of one acre in drying - -			2454	3	0
64 dr. of grass afford of nutritive matter 2 dr. The produce of the space, ditto - - $3\frac{1}{2}$	2382	3=	148	14	3

LXXXIV. *Agrostis fascicularis.* Huds. Var. canina. Curt.
Tufted-leaved bent. Nat. of Britain.

At the time of flowering, the produce from a light sandy soil is—

Grass, 4 oz. The produce per acre - -	43560	0=	2722	8	0
80 dr. of grass weigh when dry - 20 dr. The produce of the space, ditto - 16	10890	0=	680	10	9
The weight lost by the produce of one acre in drying - -			2041	14	0
64 dr. of grass afford of nutritive matter 2 dr. The produce of the space, ditto - 2	1361	4=	85	1	4

LXXXV. *Festuca pinnata.* Bromus pinnatus. Engl. Bot. 730.
Spiked fescue. Nat. of Britain.

At the time the seed is ripe, the produce from a light sandy soil, with manure, is—

Grass, 30 oz. The produce per acre - -	326700	0=	20418	12	0
80 dr. of grass weigh when dry - 32 dr. The produce of the space, ditto - 192	130680	0=	8167	8	0
The weight lost by the produce of one acre in drying - -			12251	4	0
64 dr. of grass afford of nutritive matter 1.1 dr. The produce of the space, ditto - $9.1\frac{3}{4}$	6380	13=	398	12	13

LXXXVI. *Panicum viride.* Curt. Lond. Engl. Bot. 875.
Green panic grass. Nat. of Britain.

At the time the seed is ripe, the produce from a light sandy soil is—

Grass, 8 oz. The produce per acre - -	87120	0=	5445	0	0
80 dr. of grass weigh when dry - - 32 dr. The produce of the space, ditto - $51\frac{1}{5}$	34848	0=	2178	0	0
The weight lost by the produce of one acre in drying - - -			3267	0	0
64 dr. of grass afford of nutritive matter 1.2 dr. The produce of the space, ditto - - 3	241	14=	127	9	14

LXXXVII. *Panicum sanguinale.* Curt. Lond. Engl. Bot. 849.
Blood-colored panic grass. Nat. of Britain.

At the time the seed is ripe, the produce from a sandy soil is—

Grass 10 oz. The produce per acre - -	108900	0=	6806	4	0
64 dr. of grass afford of nutritive matter $1.0\frac{2}{16}$ dr.	1914	4=	119	10	4

This and the preceding species are strictly annual, and from the results of this trial their nutritive powers appear to be very inconsiderable. The seed of this species Mr. Schreber describes (in Beschreibung der Graser) as the manna grass. In Poland, Lithuania, &c., it is collected in great abundance, when, after being thoroughly separated from the husks, it is fit for use. When boiled with milk, or wine, it forms an extremely palatable food, and is most commonly made use of whole, in the manner of sago, to which it is in general preferred.

LXXXVIII. *Agrostis lobata.* Curtis, lobata et arenaria.
Lobed bent-grass.

At the time of flowering, the produce from a sandy soil is—

	oz.		or lbs. per acre.		
Grass, 10 oz. The produce per acre - -	108900	0=	6806	4	0
80 dr. of grass weigh when dry - - 40 dr. The produce of the space, ditto - - 80	54450	0=	3403	2	0
The weight lost by the produce of one acre in drying - - -			3403	2	0
64 dr. of grass afford of nutritive matter 3 dr. The produce of the space, ditto - 7.2	5104	11=	319	0	11

LXXXIX. *Agrostis repens.* Wither. Bot. A. nigra.
Creeping-rooted bent, black bent. Nat. of Britain.

At the time of flowering, the produce from a clayey loam is—

Grass, 9 oz. The produce per acre - - -	98010	0=	6125	10	0
80 dr. of grass weigh when dry - - 35 dr. The produce of the space, ditto - - 63	42879	6=	2679	15	6
The weight lost by the produce of one acre in drying - - - - -			3445	10	10
64 dr. of grass afford of nutritive matter 3 dr. The produce of the space, ditto - - 6.3	4594	3=	287	2	8

XC. *Agrostis mexicana.* Hort. Kew. i. p. 150.
Mexican bent-grass. Nat. of S. America. Introduced, 1780, by M. G. Alexander.

At the time of flowering, the produce from a black sandy soil is—

Grass, 28 oz. The produce per acre - -	304920	0=	19057	8	0
80 dr. of grass weigh when dry - - 28 dr. The produce of the space, ditto - 156.3⅕	106722	0=	6670	2	0
The weight lost by the produce of one acre in drying - - - - -			12387	6	0
64 dr. of grass afford of nutritive matter 2 dr. The produce of the space, ditto - - 14	9528	12=	595	8	12

XCI. *Stipa pennata.* Engl. Bot. 1356.
Long-awned feather grass. Nat. of Britain.

At the time of flowering, the produce from a heath soil is—

	oz.		or lbs. per acre.		
Grass, 14 oz. The produce per acre - -	152460	0=	9528	12	0
80 dr. of grass weigh when dry - - 29 dr. The produce of the space, ditto - - 81⅕	55266	12=	3454	2	12

Grass, 102 oz. The produce per acre - -	111780 0=	69423	1	0
80 dr. of grass weigh when dry - 48 dr. The produce of the space, ditto - 979⅕	666468 0=	41654	4	0
The weight lost by the produce of one acre in drying - -		27769	8	0
64 dr. of grass afford of nutritive matter 1.3 dr. The produce of the space, ditto - 44.2¾	30372 0=	1898	4	0

Of the time in which different Grasses produce Flowers and Seeds.

To decide positively the exact period or season when a grass always comes into flower, and perfects its seed, will be found impracticable; for a variety of circumstances interfere. Each species seems to possess a peculiar life, in which various periods may be distinctly marked, according to the varieties of its age, of the seasons, soils, exposures, and mode of culture.

The following table, which shows the time of flowering, and the time of ripening the seed of those grasses growing at Woburn which are mentioned in the Experiments, must therefore only be considered as serving for a test of comparison, for the different grasses growing under the same circumstances.

Names.	Time of flowering.	Time of ripening the seed.
Anthoxanthum odoratum	April 29	June 21
Holcus odoratus	April 29	June 25
Cynosurus cæruleus	April 30	June 20
Alopecurus pratensis	May 20	June 24
Alopecurus alpinus	May 20	June 24
Poa alpina	May 30	June 30
Poa pratensis	May 30	July 14
Poa cærulea	May 30	July 14
Avena pubescens	June 13	July 8
Festuca hordiformis	June 13	July 10
Poa trivialis	June 13	July 10
Festuca glauca	June 13	July 10
Festuca glabra	June 16	July 10
Festuca rubra	June 20	July 10
Festuca ovina	June 24	July 10
Briza media	June 24	July 10
Dactylis glomerata	June 24	July 14
Bromus tectorum	June 24	July 16
Festuca cambrica	June 28	July 16
Bromus diandrus	June 28	July 16
Poa angustifolia	June 28	July 16
Avena elatior	June 28	July 16
Poa elatior	June 28	July 16
Festuca duriuscula	July 1	July 20
Milium effusum	July 1	July 20
Festuca pratensis	July 1	July 20
Lolium perenne	July 1	July 20
Cynosurus cristatus	July 6	July 28
Avena pratensis	July 6	July 20
Bromus multiflorus	July 6	July 28
Festuca loliacea	July 1	July 28
Poa cristata	July 4	July 28
Festuca myurus	July 6	July 28
Aira flexuosa	July 6	July 28
Hordeum bulbosum	July 10	July 28
Festuca calamaria	July 10	July 28
Bromus littoreus	July 12	Aug. 6
Festuca elatior	July 12	Aug. 6
Nardus stricta	July 12	Aug. 6
Triticum (species of)	July 12	Aug. 10
Festuca fluitans	July 14	Aug. 12
Festuca dumetorum	July 14	July 20
Holcus lanatus	July 14	July 26
Poa fertilis	July 14	July 28
Arundo colorata	July 16	July 28
Poa (species of)	July 16	July 30
Cynosurus erucæformis	July 16	July 30
Phleum nodosum	July 16	July 30
Phleum pratense	July 16	July 30
Elymus arenarius	July 16	July 30
Elymus geniculatus	July 18	July 30
Trifolium pratense	July 18	July 30
Trifolium machrorhizum	July 18	July 30
Sanguisorba canadensis	July 18	July 30
Bunias orientalis	July 18	July 30
Medicago sativa	July 18	Aug. 6
Hedysarum onobrychis	July 18	Aug. 8
Hordeum pratense	July 20	Aug. 8
Poa compressa	July 20	Aug. 8
Poa aquatica	July 20	Aug. 8
Bromus cristatus	July 24	Aug. 10
Elymus sibiricus	July 24	Aug. 10
Aira cæspitosa	July 24	Aug. 10
Avena flavescens	July 24	Aug. 15
Bromus sterilis	July 24	Aug. 20
Holcus mollis	July 24	Aug. 20
Bromus inermis	July 24	Aug. 20
Agrostis vulgaris	July 24	Aug. 20
Agrostis palustris	July 28	Aug. 28

Names.	Time of flowering.	Time of ripening the seed.
Panicum dactylon	July 28	Aug. 28
Agrostis stolonifera	July 28	Aug. 28
Agrostis stolonifera (var.)	July 28	Aug. 28
Agrostis canina	July 28	Aug. 28
Agrostis stricta	July 28	Aug. 30
Festuca pennata	July 28	Aug. 30
Panicum viride	Aug. 2	Aug. 15
Panicum sanguinale	Aug. 6	Aug. 20
Agrostis lobata	Aug. 6	Aug. 20
Agrostis repens	Aug. 8	Aug. 25
Agrostis fascicularis	Aug. 10	Aug. 30
Agrostis nivea	Aug. 10	Aug. 30
Triticum repens	Aug. 10	Aug. 30
Alopecurus agrestis	Aug. 10	Sept. 8
Bromus asper	Aug. 10	Sept. 10
Agrostis mexicana	Aug. 15	Sept. 25
Stipa pennata	Aug. 15	Sept. 25
Melica cærulea	Aug. 20	Sept. 30
Phalaris canariensis	Aug. 50	Sept. 30
Dactylis cynosuroides*	Aug. 30	Oct. 20

Of the different Soils referred to in the Appendix.

In books on agriculture and gardening much uncertainty and confusion arise from the want of regular definitions of the various soils, to distinguish them specifically by the names generally used: thus the term "bog-earth" is almost constantly confounded with peat-moss, and heath-soil; also the terms "light loam," "heavy soil," &c. are given without distinguishing whether that be "light" from sand, or this "heavy" from clay. In minute experiments, it is doubtless of consequence to be as explicit as possible in those particulars. The following short descriptions of such soils as are mentioned in the details of the experiment are here given for the above purpose:—

1st. By "loam" is meant any of the earths combined with decayed animal or vegetable matter.

2d. "Clayey-loam," when the greatest proportion is clay.

3d. "Sandy-loam," when the greatest proportion is sand.

4th. "Brown-loam," when the greatest proportion consists of decayed vegetable matter.

5th "Rich black loam," when sand, clay, animal and vegetable matters are combined in unequal proportions, the clay greatly divided, being in the least proportion, and the sand and vegetable matter in the greatest.

The terms "light sandy soil," "light brown loam," &c. are varieties of the above, as expressed.

Observations on the Chemical Composition of the Nutritive Matter afforded by the Grasses in their different states.—By Sir H. Davy.

I have made experiments on most of the soluble products supposed to contain the nutritive matter of the grasses, obtained by Mr. Sinclair; and I have analyzed a few of them. Minute details on this subject would be little interesting to the agriculturist, and would occupy a considerable space; I shall therefore content myself with mentioning some particular facts, and some general conclusions, which may tend to elucidate the inquiry respecting the fitness of the different grasses for permanent pasture, or for alternation as green crops with grain.

The only substances which I have detected in the soluble matters procured from the grasses are mucilage, sugar, bitter extract, a substance analogous to albumen, and different saline matters. Some of the products from the after-math crops gave feeble indications of the tanning principle.

The order in which these are nutritive has been mentioned in the first lecture: the albumen, sugar, and mucilage, probably when cattle feed on grass or hay, are for the most part retained in the body of the animal; and the bitter principle, extract, saline matter, and tannin, when any exist, probably for the most part are voided in the excrement with the woody fibre. The extractive matter obtained by boiling the fresh dung of cows is extremely similar in chemical characters to that existing in the soluble products from the grasses. And some extract, obtained by Mr. Sinclair from the dung of sheep and of deer, which had been feeding upon the Lolium perenne, Dactylis glomerata, and Trifolium repens, had qualities so analogous to those of the extractive matters obtained from the leaves of the grasses, that they might be mistaken for each other. The extract of the dung, after being kept for some weeks, had still the odor of hay. Suspecting that some undigested grass might have remained in the dung, which might have furnished mucilage and sugar as well as bitter extract, I examined the soluble matter very carefully for these substances. It did not yield an atom of sugar, and scarcely a sensible quantity of mucilage.

Mr. Sinclair, in comparing the quantities of soluble matter afforded by the mixed leaves of the Lolium perenne, Dactylis glomerata, and Trifolium repens, and that obtained from the dung of cattle fed upon them, found their relative proportions as 50 to 13.

It appears probable from these facts that the bitter extract, though soluble in a large quantity of water, is very little nutritive; but probably it serves the purpose of preventing to a certain extent, the fermentation of the other vegetable matters, or in modifying or assisting the function of digestion, and may thus be of considerable use in forming a constituent part of the food of cattle. A small quantity of bitter extract and saline matter is probably all that is needed; and beyond this quantity the soluble matters must be more nutritive in proportion as they contain more albumen, sugar, and mucilage, and less nutritive in proportion as they contain other substances.

In comparing the composition of the soluble products afforded by different crops from the same grass, I found, in all trials I made, the largest quantity of truly nutritive matter in the crop cut when the seed was ripe, and least bitter extract and saline matter; most extract and saline matter in the autumnal crop; and most saccharine matter, in proportion to the other ingredients, in the crop cut at the time of flowering. I shall give one instance—

100 parts of the soluble matter obtained from the Dactylis glomerata, cut in flower, afforded

* In the experiments made on the quantity of nutritive matter in the grasses cut at the time the seed was ripe, the seeds were always separated; and the calculations for nutritive matter, as is evident from the details, made for grass and not hay.

of sugar - - - 18 parts.
of mucilage - - - 67
of colored extract, and saline matters with some matter rendered insoluble by evaporation 15

100 parts of the soluble matter from the seed crop afforded—

of sugar - - - - 9 parts,
of mucilage - - - 85
of extract, insoluble and saline matter - - - 6

100 parts of the soluble matter from the aftermath crop give—

of sugar - - - 11 parts.
of mucilage - - 59
of extract, insoluble and saline matters - - - 30

The greater proportion of leaves in the spring, and particularly in the late autumnal crop, accounts for the difference in the quantity of extract; and the inferiority of the comparative quantity of sugar in the summer crop probably depends upon the agency of light, which tends always in plants to convert saccharine matter into mucilage or starch.

Amongst the soluble matters afforded by the different grasses, that of the Elymus arenarius was remarkable for the quantity of saccharine matter it contained, amounting to more than one-third of its weight. The soluble matters from the different species of Festuca, in general, afforded more bitter extractive matter than those from the different species of Poa. The nutritive matter from the seed crop of the Poa compressa was almost pure mucilage. The soluble matter of the seed crop of Phleum pratense, or meadow cat's-tail, afforded more sugar than any of the Poa or Festuca species.

The soluble parts of the seed crop of the Holcus mollis and Holcus lanatus contained no bitter extract, and consisted entirely of mucilage and sugar. Those of the Holcus odoratus afforded bitter extract and a peculiar substance having an acrid taste more soluble in alcohol than in water. All the soluble extracts of those grasses that are most liked by cattle have either a saline or subacid taste; that of the Holcus lanatus is similar in taste to gum arabic. Probably the Holcus lanatus, which is so common a grass in meadows, might be made palatable to cattle by being sprinkled over with salt.

I have found no differences in the nutritive produce of the crops of the different grasses cut at the same season, which would render it possible to establish a scale of their nutritive powers; but probably the soluble matters of the after-math crop are always from one-sixth to one-third less nutritive than those from the flower or seed crop. In the after-math the extractive and saline matters are certainly usually in excess; but the after-math hay mixed with summer hay, particularly that in which the fox-tail and soft grasses are abundant, would produce an excellent food.

Of the clovers, the soluble matter from the Dutch clover contains most mucilage, and most matter analogous to albumen: all the clovers contain more bitter extract and saline matter than the common proper grasses. When pure clover is to be mixed as fodder, it should be with summer hay, rather than after-math hay.

From the Genesee Farmer.

REMARKS ON THE CULTURE OF PEAS.

Crops of secondary importance are of course deserving of less attention than those which are primary; such as, in consequence of a limited market, do not readily command cash, are not so valuable to the farmer as those at all times in extensive demand. Thus, for instance, the culture of buckwheat and rye are not worthy of so much attention as that of wheat. But when a crop of secondary importance *in itself*, becomes a very useful auxiliary in the cultivation of the most important, it immediately assumes a rank of the first consequence. It is this which renders the cultivation of peas highly deserving the attention of farmers.

It has been long since satisfactorily determined that attemps to make money rapidly from land by close cropping, is the worst economy; and that on the contrary a proper system of rotation, calculated to effect a constant improvement in the soil, is, in consequence of the full and regular crops thus obtained, the best policy even for the time being. Thus an abundant crop of peas followed by one of wheat, would be more advantageous than two successive and inferior crops of wheat, independently of the effect on the land.

The peculiar excellence of peas as a preparation for wheat, is becoming well known. Their additional value as food for fattening domestic animals, especially hogs, renders the knowledge of their proper culture of much importance, and any suggestions therefore upon this subject it is presumed may not be wholly useless.

With regard to the proper soil for peas, it is commonly believed that a poor, or but moderately fertile one, is best; and that the great growth of stalk produced by very rich land, is adverse to the copious production of seed. This is doubtless generally the case, when the larger and taller varieties are sown; in these there is already a strong tendency to the growth of leaf and stalk, which is increased by a fertile soil. But this may doubtless be in a great degree if not entirely remedied, by the substitution for the taller kind, of the early and dwarf varieties, such as Bishop's dwarf prolific and the early Washington. Indeed it is not improbable that much larger crops than have been hitherto obtained, may be raised by dwarf peas thickly sown on fertile ground. Analogous proof is furnished by the fact that much larger crops of Indian corn have been raised in the northern states from the small-stalked varieties, than in the fertile land of the south and west where this plant grows of gigantic size.

An additional advantage from the use of dwarf kinds is early maturity, which is always a very desirable quality in all farm crops, if not at the expense of quantity.

What further experiments are needed and further discoveries are yet to be made in the cultivation of peas on fertile and even on highly manured soils by the use of *lime*, will be evident from the following extract from Dickson's Farmers' Companion:

"It is observed, that the common pea, whether white or gray, cannot be reared to perfection in any field which has not been either naturally or artificially impregnated with some calcareous matter. But it is remarkable, that a soil that could scarcely have brought one pea to perfection, although richly manured with dung, from their running too much to haum, and after blossoming dying away without becoming ripe, if it has had lime applied upon it, is capable, when properly prepared in other respects, of producing plentiful crops of peas ever after."

The best *time* for sowing peas is as early in the spring as practicable. It is not an uncommon practice among gardeners who cultivate peas for the table, to sow them late in autumn, and the first warm weather in the spring brings them up. The chief objection to this practice is the danger of their being destroyed by mice during winter; but this danger would be small in a clean ploughed field, and an experiment in fall sowing may be well worthy of trial, especially as it is an object to do as much of the work of the farm in autumn as practicable, in order to avoid the hurry of spring. The present is the time for such an experiment.

The *pea-bug* has always been found a serious difficulty in the culture of this crop; and as inquiries have been recently made in this paper for a description, the following is given. The insect, (*Bruchus pisi*) is of an ovate form and brownish color, particularly the elytra (or wing-sheaths) which are uniformly besprinkled with specks and lines of a light color, as well as the upper part of the thorax near the joint. The mouth is armed with a pair of serrated forceps, the under part and legs are of a very dark dusky color, and the whole insect covered with fine hair. When the pods of the pea have arrived at the state of maturity sufficient to show the small peas within them, the female deposits her eggs in the evening or on a cloudy day. These soon hatch, and the young larva eats directly into the young pea, and remains feeding on its contents until it changes into a chrysalis, which takes place before the ensuing spring. The perfect insect emerges during the warm weather, generally about the time of sowing peas. They do not generally leave their habitations until after the peas are planted, (unless purposely exposed to the hot sunbeams,) when they creep out and remain until new crops invite them; after they have deposited their eggs they perish. When the peas are green and scarcely full grown, the presence of the worm is scarcely discernible, and does not affect the taste; but when they are quite ripe, there is nothing but a shell enveloping a fat chrysalis. A most remarkable fact is that they never injure the plumula or sprout, for almost every pea occupied by the insect, grows and thrives vigorously notwithstanding nearly the whole of the internal part appears to be consumed. This remarkable instinct is necessary for their existence; for if the seed were destroyed, it would end in the extermination of their race.

Several methods have been proposed for destroying this insect or eluding its depredations. Soaking them for a minute in boiling water, which does not destroy their vitality, has been repeatedly and confidently recommended as an effectual mode for their destruction. But a correspondent in the second number, current volume, of this paper says, "I poured boiling water upon the peas and let them stand till the water cooled. I then poured off the water and commenced sowing my peas, when to my astonishment the bugs were crawling about as lively as ever." He adds that the vitality of the seed was greatly injured, as not one-half of them came up. A better remedy appears to be in always sowing clean seed. But where, it is asked, is this to be obtained? Clean seed may be procured from Canada; or it may be had by sowing a portion of the field very late, or with old peas, for this particular purpose. It appears that this insect disappears from the seed before the middle of the sixth month (June) and consequently sowing later than this time, or not until the following spring, for the purpose of obtaining seed, would be effectual. Of these two methods, however, sowing seed 2 years old is on the whole undoubtedly the best. By this time, the insect has lived out its period, and no danger from it is to be apprehended.

Peas fed to hogs immediately after harvesting are not hurt for that purpose by the bug.

A very convenient way of raising and feeding peas to hogs is to plant successive crops in different fields, and to allow them to be eaten on the ground. At the time the peas are beginning to harden, they will eat the leaves and stalks as well as the seed. This method is particularly applicable to the fattening of large herds upon land which is cheap and where labor is expensive.

As it is desirable to procure the best varieties of the pea for seed, so it is requisite that care be taken to prevent their deterioration. They seem to be peculiarly liable to change—to improvement by proper care, as well as degeneracy by neglect. It has been observed in the culture of the early Washington, that seed from the same origin differs greatly, merely from the management it receives. Genuine seed of this variety may be obtained, which will ripen a week or two later than other seed, also genuine. The quality of early maturity may be greatly increased or lessened, by always selecting the portion first ripe for sowing, or by picking the earliest for the table, and using the remainder for seed. The following statement in the third volume of the Genesee Farmer, by L. Couch, is well deserving of attention:—

"There is no seed that I am acquainted with that will degenerate more rapidly than peas. The process that I have pursued for *two years* with my seed peas, is simply sifting them in a sieve that will let through the small peas and the small seeds of every description, and leave the largest and the best of the peas to sow. By this means my peas have improved *at least twenty-five per cent. in quality.* I think it answers all the purpose of scalding to clean them of the bugs. By sifting them the bug or nit is shaken out of the peas and left with the rubbish, which is given to hogs."

With regard to other points in the culture of this crop, it may be briefly observed—that plaster, as on clover, operates to the most decided advantage; that a clover sod turned over late in the fall, is an excellent preparation for sowing the following spring; that as deep planting is less liable to prevent vegetation than in most seed, when sown upon a light or dry soil, they should always be buried by a shallow furrow of the plough; that when fed upon the ground to hogs, two or three quarts of oats to the acre intermixed, will afford an excellent support for them during their growth; and that by far the best and most expeditious method of harvesting them is by means of a common horse rake. J. J. T.

From the Southern Agriculturist.

ON THE IMPROVEMENT OF SOILS IN SOUTH CAROLINA BY MARL.

Mr. Editor,—I take great pleasure in handing for publication, a communication submitted to the South Carolina Agricultural Society, by Dr. Joseph Johnson, on the subject of marl as a manure. It is one fraught with valuable consequences to the whole state, and particularly the lower sections. All lands in the vicinity of a metropolis become more valuable from proximity to a market, and whatever can restore its fertility, demands great consideration. The community therefore are indebted to individuals who offer the means of effecting such a purpose, and when suggestions emanate from so philosophic and practical a mind as Dr. Johnson's, they demand attention and patient experiment. Many sections of country in the vicinity of Charleston, and particularly along the rivers, contain large beds of marl, and the suggestions thrown out may easily be tested. The fertile soil may be sought (as familiary entitled) to the far west, yet even there its properties are not more enduring that at home, and when we consider the privations of possession, of separation from kindred, early association broken, and loss of polished society, which must be all forgone in seeking a due return for labor, it surely becomes us to secure advantages nature presents at home. Let us listen to those then who lure her treasures from her, and avail ourselves of the blessings she tenders. Let us ascertain and estimate the advantages we enjoy. We will then revel under the shade of our own vine and our own fig tree, and our hearts will rejoice with the endearing recollections of home, around the cherished hearths of our ancestors.

The concurrence of Dr. Johnson in publishing his remarks, was politely granted to the corresponding secretary.

R. W. ROPER.

Communication of DR. JOS. JOHNSON, *to the Agricultural Society of South-Carolina, on the Improvement of Soils by Marl and Lime, &c.*

Charleston, 20*th August*, 1838.

Gentlemen,—Most of you have seen the papers occasionally published in the Southern Agriculturist and other periodicals, on the uses of marl and lime as manures for sandy sour, and exhausted lands. Ruffin's Essay on Calcareous Manures, has no doubt been read, by most of you; but you may not be as well informed, that these valuable manures are found in almost every part of our middle and low country; and on the banks of the Savannah, Edisto, Ashley, Cooper, Santee and Pedee rivers, and on many of the intermediate inferior water-courses.

Mr. Wm. Scarborough, who lived 15 or 20 years ago, on the Lower-Three-Runs in Barnwell District, told me that he had accidentally discovered a bed of marl in digging a ditch, and applied it to his very poor high land, in the proportion recommended by agriculturists. Even in the first year, the benefit was very evident; in the second it was greately increased, and in the third year, the produce of his marled land was threefold greater than it ever had been previous to the addition of marl.

Mr. Morton A. Waring tried it one year only, on a piece of land which he then owned on Ashly river. The produce was increased even in that first year about 50 per cent., but as he then sold the place he did not know whether it had been cultivated in the succeeding years or not.

Mr. James B. Richardson, the present representative from Sumter district in our state legislature, told me that he had procured some fossil shells from Santee river, made lime of them, and applied the lime to some of his old fields, which had once been first rate land. The consequence was, that they became more productive than they ever had been, even when first cleared. Some of you may know of other instances of success, I never heard of a failure where the cultivation was continued.

But practical knowledge is much wanted on this subject; and even if the proportion of marl to each acre recommended by the most approved writers on this subject, be applied to our lands, some difference may be discovered in our soils, or in our marls, or in some other respect.

It is first of all desirable to know whether the marl within our reach, is composed of lime, clay and sand, in proportions which would encourage us to dig and cart it to our old fields. This question will be readily answered by any gentleman acquainted with chemistry. I have analyzed several specimens, and will cheerfully continue to afford every information in my power. All marls effervesce if vinegar be poured on them, and this test is within the reach of every inhabitant, however distant he may be from those who can give more certain and correct information.

It is next desirable to know at what time, and in what quantities, marl should be laid on the fields. These questions I request of your society to have ascertained by the experiments of practical men. I suggest that the time which can be best spared for such works, is the best time. When the crop is laid by in the summer, the marl may be dug out and left to dry in heaps. In the winter it may be carted into the fields, and scattered in the trenches to moulder until the spring, when the plough can do all that is farther necessary. Mr. Ruffin thinks that the best way is to keep one man constantly employed with a horse and cart, all through the year, and that 60 acres may be thus effectually manured in one year, requiring no other or additional manure for 7 or 8 years.*

The quantity required varies from 200 to 300 bushels per acre, according to the quality of the marl and the nature of the land. The cost of manuring would therefore be from $2 to $5 per acre, which I suppose to be cheaper than clearing land, where the wood cannot be sent down to a market. If the returns for this expenditure, equal those reported in Virginia and New-Jersey, the crop will be increased three-fold, say from 10 to 30 bushels per acre. The profit would therefore be increased not only $20 per acre for one year, but as no other manuring is required for 7 or 8 years, it would be at least $120 per acre, returned for $5 expended. If 20 acres be cultivated in corn by one boy and horse, he will make for his owner $500 or $600

* The last words of this passage do not correctly convey the opinions of the work intended to have been quoted. Marl is there considered as a *permanent* manure.—ED. FARM. REG.

per annum, corn being supposed to sell at $1 per bushel. In affording this profit, he would only work at the crop three or four months, all the rest of the year, he might be employed in marling other lands.

So many laborers have been taken off from the cultivation of provisions in the United States, to become the consumers of provisions, while laboring in the construction of Rail-Roads and other public works, that provisions cannot be otherwise than dear, for many years to come. The planter who most successfully cultivates provisions, will therefore be best rewarded, while cotton is at the present moderate rates.

But, gentlemen, there are other considerations of great importance to most of us. Most of us have children, relatives and friends, who have left the state and gone westwardly, to seek for new lands. Many more, distinguished for talents and enterprise and public spirit, may be expected to follow, unless something can be done at home to afford them profitable occupation. The rank of South-Carolina among her sister states, will be diminished in proportion to her diminished population and productions. I trust that something may yet be done, not only to arrest this emigration, and render agriculture more profitable, but to render the number of persons engaged in agriculture, much more numerous than has ever been known, at least in the middle and lower portions of the state. Are not the most of you, gentlemen, owners of uncultivated lands in this portion of the state, for which there has hitherto been no demand, nor any prospect of their being wanted, for cultivation? If by the successful use of marl and shells, the old fields in their vicinity can be increased in their productions, from 10 to 30 bushels per acre, would not the value of such lands be increased in proportion, and would not you, the proprietors, find your property doubled in value by the discovery? Would not all other lands in the vicinity of the marl and shells, although never settled, be improved in proportion with the old fields, and will not the proprietors reap the benefit, whatever that may be?

If you can make it appear to a farmer that he can live with his family in a pine land settlement, enjoying health and every other comfort in life, while he can lay up $400 or $500 per annum, from the work of every one of his family who can plough a neighboring field; are not such men likely to become settlers on these vacant lands, and increase their value? Are they not more likely to settle on these lands, when they ascertain that they may cultivate both a winter and a summer crop in the same year? If these advantages be made known in Europe, are not the skilful experienced peasantry in the north of Italy, in Switzerland, Germany, Holland, Poland, and other parts of Europe, likely to collect in this part of our state, and form a population of hardy yeomen, who would quiet all apprehensions of a domestic nature? With such prospects and probabilities, is it not worth our while, to set on foot a series of experiments, for the purpose of ascertaining how far the marl and shells found in South-Carolina, may be made to increase the agricultural productions of the country?

Lime and marl are the most durable of all manures; but the latter, in particular, requires about three years to perfect its influence over the land. It will therefore be necessary to continue the experiment at least three years in succession; it may also be expedient to manure and cultivate a new piece of adjacent ground each year, by way of testing what had preceded.

With much deference, I propose that your society offer a premium for the best series of experiments with marl found in South-Carolina, on a stated quantity of sandy land, and continued three years—the quantity of marl applied to each acre, and the productions of each acre being distinctly reported to the society, with any other circumstance deemed important by you.

The same premium for the same experiments on clay land.

The same premium for the same experiments with unburnt, pulverized or mouldering shells, or loose limestone, both on sandy and clay lands.

The same premium for the same experiments with lime burnt from shells, or from loose limestone, both on sandy and clay lands.

I beg leave to submit these suggestions for the consideration of the Agricultural Society, subject, of course, to any amendments or alterations that they may think expedient. Their greater knowledge and experience must dictate.

I am, very respectfully,
Your most obedient servant,
Jos. Johnson.

To the President and Members of the Agricultural Society.

From the Southern Agriculturist.

GRASSES, ETC. FOR SHEEP.

Mr. Editor,—As your valuable work is open to all subjects connected with the husbandry of our country, and more particularly this southern portion of it, I beg leave to occupy a small space. The growing of wool does not much interest us at present, but the time is coming when it may be necessary for us to make every edge cut. Whether so or not, there are always among us those who are found of good and sound mutton, and many who are deterred from raising sheep by fear of the rot, and other disorders. My experience may remove a portion of that fear. I take no more than ordinary care of mine in winter, but I observe in the pine barren where they pasture, a species of creeping pepper grass of which they are very fond. It comes up early in February, and dies in the summer. The stimulating warmth of this food, preserves them in health, and keeps them free of the rot, and other diseases so fatal to sheep, in cold rainy seasons. Those who have the pepper grass, and desire to raise sheep, should encourage the growth of it. There are other plants and grasses, which being pungent, will answer eqally well, and of which sheep are fond. Among them are mint, penny-royal, and parsley. Satisfied with my spontaneous growth of pepper grass, I have not cultivated either of the last mentioned aromatics, but I think their having a good effect on sheep cannot be doubted. I would advise cultivation of the pepper grass however, in preference, but only because it is more proper and natural to recommend more highly what I *know*, than what I only believe, no matter how confidently. It is certain however that sheep take freely all the plants I have named. If this communication instructs but one individual, I shall be happy in having done some little, towards advancing the husbandry of my native state.

Edgefield. A FARMER.

For the Farmers' Register.

ROUGH FIELD NOTES.

No. II.

Philadelphia and Reading Rail-Road.

There is no work in Pennsylvania more interesting, or, as far as finished, better executed than this. For several months the navigation of the Schuylkill improvement is closed by ice, and great difficulty is experienced in transporting coal from the extensive coal region of Pottsville, and that section of the state, to market. To remedy this evil was the Philadelphia and Reading railway projected. When completed, it will not stop, as its name would indicate, at Reading, but will extend to Pottsville, a distance of 93 miles, and will there connect with the rail-road from that place to Sunbury, and also with the numerous little roads radiating from Pottsville to every coal mine in the neighborhood. When this road shall have been finished to the coal region, the amount of transportation it will do will be immense.

From Philadelphia, to a point opposite Norristown, 18 miles, the road is yet unfinished. The traveller, for the present, leaves Philadelphia on the Norristown rail-road, and, at its termination, crosses over to the Reading road, which is completed from that point to Reading, a distance of forty miles. Between Reading and Pottsville, ground has just been broken; but, from the energy and success with which this great work has heretofore been prosecuted, there is no doubt but that it will steadily progress till completed.

This road all the way pursues the valley of the Schuylkill, being located on the southern side for thirty miles from Philadelphia, and then crossing to the northern. With a few exceptions, it conforms to all the windings of the river, and its location partakes of the same general nature as that of the Baltimore and Ohio rail-road along the valley of the Patapsco, except that the bends of the Schuylkill being generally less sudden and the valley wider, more gentle curves have been obtained throughout. There is no curve between Philadelphia and Reading with a radius less than 950 feet, and, with one or two exceptions, the curves have radii as much as 2000 feet, or more. The hills sometimes encroach on the river, confining the roadway, and causing either deep side-cutting, oftentimes through rock, or expensive walling on the river side. Near Phœnixville, the Schuylkill makes a circuitous bend of three miles, and returns to within half a mile of the place from which it set out, forming a bold promontory one and a half miles long, and only half a mile across the neck. To save the three miles of distance, and, at the same time, to avoid much bold curvature, it was determined to tunnel under this neck of land, which is a spur from the main ridge. This tunnel was commenced in 1835, and has been successfully carried through. It is the greatest work of the kind in America, and no man ought to visit Philadelphia without going to see this triumph of art. It is 1932 feet long, 19 feet wide, and 17 feet high, with an elliptical arch. It is cut through a dark-colored graywacke slate, from which it derives its name of "Black Rock tunnel." It was excavated from both ends as well as from six vertical shafts. These shafts are eight feet in diameter, and were sunk in pairs to enable the miners the better to keep the true line of direction. The deepest shaft is 140 feet deep. A true and accurate line has been obtained through the tunnel for the rail-road, showing the accuracy with which it was excavated, and the greatest care and attention on the part of the resident engineer. The cost of the shafts, per cubic yard, was $20, and of the tunnel itself, $5. The whole cost of this tunnel was about $170,000. On the first division of this road, there is also another tunnel, about 900 feet long, not yet completed: and it is more than probable that there will be another near Port Clinton.

Immediately at the far end of Black Rock tunnel, and on a line with it, is a handsome bridge of hewn sandstone, across the Schuylkill, by means of which the rail-road crosses to the northern side of the river. This viaduct has four arches, each with a span of 72 feet, and a rise of $16\frac{1}{2}$ feet. Each arch is the arc of a circle, and contains 53 ring-stones, which measure 30 inches in depth. The road-way is $16\frac{1}{2}$ feet in the clear between the parapets, which are of sandstone, 2 feet wide, and project two feet above the road-way. The piers are not what are termed abutment piers, being only eight feet thick. The wings of the abutments have a radius of $18\frac{1}{2}$ feet, and terminate by steps descending to the surface of the ground. The execution of this costly bridge is good, but the architectural effect is not pleasing. The very slight projection of the pilasters which go up from the piers, and the nicety with which the material has been cut, give a delicacy of appearance altogether unbecoming a structure of this nature. The arches, too, springing at an elevation of only six feet above ordinary water, would have looked better had they been elliptical, instead of circular, particularly if the faces of the piers had also been slightly curved. The Thomas viaduct across the Patapsco on the Washington branch rail-road, produces a much finer effect, and is not surpassed by any similar work in our country. The Thomas viaduct is built of unhewn granite of the best quality. It is 660 feet long, 66 feet above the surface of the water, and consists of 8 circular arches of 60 feet span each. Each abutment is 60 feet long, and terminated by strong buttresses on each side. Heavy pilasters also go up from every pier. The road-way is 22 feet wide, and is confined on either side by a heavy iron railing, $3\frac{1}{2}$ feet high on the top of the parapet, which is $2\frac{1}{2}$ feet wide. The whole work presents the appearance of great strength and stability. The cost of this bridge was $120,000. It is worthy of note, that this immense bridge is built on a curve, with a radius, to judge by the eye, of 2800 feet.

In the construction of the bridge across the Schuylkill, the necessary precautions were not taken to guard against ice, which frequently comes down that river in great quantities. The piers below high-water-mark should have been built on the upper side circular, and with a slope of at least 45°, like the piers of the Alexandria aqueduct. Instead of which, however, the piers are built perfectly perpendicular. Since the bridge was finished, they have placed just above each pier what they call ice-breakers, (of wood,) but which forcibly remind one of chicken-coops of the present day, and which I have no doubt equalled in expense, the additional cost of the piers, had they been constructed in the proper manner in the beginning.

At the east end of Black Rock tunnel, is a long rock cut, 30 feet deep. The effect of passing rapidly in the train through this cut, the walls of which stand almost vertical, then through the tunnel, which, notwithstanding its 6 shafts, is as dark within as midnight, and dashing across the bridge to the opposite side of the river, with the sudden transition from darkness to light, all in a moment, can hardly be conceived.

As is generally the case with all roads located in the valleys of rivers, on this a great number of bridges of various sizes are necessary for crossing the many tributaries of the Schuylkill. The principal stone structure has been already described. With that exception, for all spans exceeding forty feet, the lattice bridge is used. It is worthy of note, that all the bridges of this kind, notwithstanding the short time the road has been in operation, have settled between the piers. This is owing, I think, to the fact, that they are built for a double track, and that only one has been put down and is in use. The consequence is, that every time a train passes, at least three-fourths of the whole weight is thrown on one side of the bridge, or one set of lattice. This evil may be remedied by a third set of lattice between the two tracks, thus making, as it were, a separate and independent bridge for each track. This additional lattice may be put in, at not much additional cost; and that it is necessary when two tracks are required, is sufficiently proven by the lattice bridges, not only on this road, but throughout the state. This settling has taken place to so great an extent on the Danville and Pottsville railroad, that they are now putting wooden supports between their regular piers.

The Reading railroad was graded throughout for two tracks, but only one has been as yet laid. The superstructure consists of wooden sills, (principally of oak,) 7 × 8 inches, bedded 3 feet 3 inches apart, on beds of broken stone 14 inches deep. Trenches are first dug at the proper distances apart and well rammed. The broken stone is then put in, in three different layers, each layer also being well rammed. On the sills is fastened the T rail, weighing 45 lbs. to the running yard. The rails are 19 feet long, and only rest on cast-iron chains at their extremities. To the intermediate sills they are merely fastened by spikes with *catch* heads. The superstructure was not laid till the banks had had a winter to settle, and is now in admirable adjustment.

There is no grade between Philadelphia and Reading over 18 feet to the mile. This is a most striking feature in this road. An engine without difficulty, will carry 200 tons down to Philadelphia. The fuel used is *coke*, obtained from the gas works. It is found to answer very well. On the Baltimore and Ohio road, anthracite coal is used. Two tons are found necessary to go from Baltimore to Harper's Ferry. An experiment or two had been tried with bituminous coal, and 1 ton 14 cwt. were found to do the same work.

The Philadelphia and Reading railroad passes through a highly interesting country. The scenery of the Schuylkill is not so picturesque as that of the Potomac, but the neat farms and farmhouses, and frequent villages, furnish employment for the eye of the traveller. Just below Reading, the river breaks through the first ridge of hills, under the name of "Never-Sink Mountain."

The cost of this railroad and all its fixtures will be $45,000 per mile.

Danville and Pottsville Railroad.

This road extends from Pottsville, at the head of the Schuylkill improvement, 40 miles to Sunbury, on the Susquehannah. Its object was to transport coal from the anthracite coal region, through which it passes in either direction, to the Schuylkill, or to the Susquehannah. The construction of this road was premature, and the consequence is, that the 12 miles next to Pottsville are not in use, that the next 8 miles have never been finished, and that only 20 miles of it from Shamokin to Sunbury are now used. It is supposed, however, that by the time the Reading railroad is completed to Pottsville, that the completion of this work will be loudly called for.

This road necessarily crosses the dividing ridge between the Schuylkill and Susquehannah, and the inclined planes by which it rises and falls from the summit of the Broad Mountain constitute the most remarkable and interesting feature in this work. Between Pottsville and Girardsville, a distance of only 12 miles, there are not less than six inclined planes, 4 ascending and two descending.

Plane	No.	1	rises	176	feet	in	600	feet
"	"	2	"	200	"	"	850	"
"	"	3	"	130	"	"	600	"
"	"	4	"	130	"	"	800	"
"	"	5	falls	345	"	"	1600	"
"	"	6	"	150	"	"	900	"

In passing over these planes on horseback it is with difficulty that the horse can be led up and down them. All these planes except No. 5 have the same angle of inclination throughout. No. 5 is gradually curved, beginning very precipitously at top, and by degrees becoming more and more gentle towards the bottom. They all have curves approaching within a short distance of their foot, which is decidedly objectionable. The planes have double tracks, and the same sills extend under both. Friction rollers are placed every 25 feet. At the head of plane No. 5, which has a most imposing appearance, is a stationary engine. From Pottsville the road follows the western side of a rugged and precipitous ravine for eight miles. There is much heavy rock cutting and stone walling. Plane No. 4 brings you to the top of Broad Mountain, a bleak and inhospitable region. The eye in vain looks around for any trace of cultivation. For two miles the road keeps on this mountain and descends by plane No. 5 into the valley of the Mahanoy. Between Girardville and Shamokin, the link yet incomplete, one or two inclined planes will be required.

Shamokin is a small and new village, situated at the head of a creek of the same name, which empties into the Susquehannah just below Sunbury. Its origin was the coal trade, and all its inhabitants are colliers and miners. From this place to Sunbury 20 miles, the rail-road winds down the valley of the Shamokin with generally easy curves through a country, the last half of which is highly cultivated. Grading on this portion is remarkably light, for a road in the midst of mountains. As the road approaches Sunbury it crosses the Shamokin three times by handsome lattice bridges, which, however, have settled very much. I have rarely passed through a region so wild and dreary as that between Pottsville and Shamokin. I was particularly struck with the beauty and grandeur of the hemlock tree, which abounds along the road. When young it contrasts well with, and when old seems well suited to, the rugged cliffs it overshadows.

Just at the head of inclined plane No. 1, is a small tunnel 800 feet long, 10 feet wide and 11 feet high, with a circular arch. It was excavated entirely from the two ends. The material excavated was earth with a small quantity of coal. The sides are walled with stone, and the top arched with brick. The whole cost was $26,000.

This road has been graded for two tracks, but only one has been laid. The superstructure consists of heavy sills bedded every five feet on broken stone, into which is keyed a wooden rail 9×5 inches. The iron plate measures 2 by $\frac{5}{8}$ inch.

From Pottsville to Girardville, 12 miles, cost $400,000. From Shamokin to Sunbury, 19 miles, cost $180,000.

PROCEEDINGS OF THE FREDERICKSBURG AGRICULTURAL SOCIETY.

[Published by request of the Society.]

Tuesday, Nov. 8, 1838.

At 12, M., the society was called to order—James M. Garnett in the chair, and Robert B. Semple, Secretary.

This was a called meeting, for the purpose of reviewing the report of the revising committee on the constitution and by-laws. Report was made through the chairman, Wm. P. Taylor, asking (for reasons therein stated) further time for the committee to discharge its duties, which report was accepted, and the society adjourned.

Annual Meeting—Nov. 9.

The society was called to order by the late secretary, when, on motion, the rule requiring the election of officers by ballot, was suspended, and the society proceeded to the election of their officers for the ensuing year.

On motion of James Richards, James M. Garnett was unanimously re-elected president. George Hamilton having declined a re-election, Francis W. Taliaferro was elected 1st vice president, and Wm. P. Taylor, 2d vice president.

Robert B. Semple (the late secretary) asked to be excused from the further duties of secretary and treasurer, when, at his consent, he was on motion, appointed secretary and treasurer, *pro tem.*

The society then proceeded to vote upon the admission of new members, and the selection of committees, preparatory to the show and fair, and at 12, M., adjourned to witness the exhibition.

Afternoon session.

James M. Garnett in the chair, when the several committees reported.

The committee on stallions, jacks and mules, report—that they examined two stallions, one owned by Mr. Taylor, and the other by Mr. Alcocke. Both horses were in bad condition, but they award the premium to Mr. Alcocke's horse, Corsair, as they consider him the best looking horse of the two.

They also report—that they examined a jack, the property of Mr. Thomas Rowe, of Caroline, to whom they awarded a premium of $10.

They also report—they examined a very fine mule colt of Mr. John C. Browne, two years old, for which they award a premium of $5.

John H. Lee, *Chairman.*

The committee on mares, colts, fillies and riding horses, have performed the duties assigned them, and beg leave to submit the following report: They award the premium for the best colt to Mr. George Morton's Truffle, two years old last spring. They award a premium for the best brood mare to Mr. Robert Wallace's mare, by———, which had a fine colt at her foot, by Priam. They award to Thomas Chandler a premium for the finest riding horse, though this was not a bloodless victory—it being hard to decide between his horse and a fine sorrel owned by Mr. P. B. Winston, of Louisa—all of which is respectfully submitted.

James Richards, *Chairman.*

The committee on beef, sheep and mutton, beg leave to report—that they award the premium on mutton to John B. Gray, of Stafford, and for the best grass-fatted beef, being the only one exhibited, (although a very fine one) to Zephaniah Turner, of Rappahannock county. For the best fatted work ox, to Lewis Shumate, of Fauquier county.

George Rowe.

The committee on bulls and milch cows, award the premium for the best bull, (half Devonshire,) to Mr. Hay Taliaferro, of King George. Mr. Green exhibited a fine milch cow, but having no pedigree, the committee did not award a premium.

R. T. Willis, *Chairman.*

The committee of agricultural implements, report—that the implements exhibited were a cultivator, an ox-yoke, a hand-drill, and a cutting-box. The three first, by Mr. James M. Garnett, and the last, an instrument made at the Fredericksburg foundry. These implements were not offered for premiums, and were not tested by actual trial, and therefore none is recommended; but they think proper to say that they appear to be well adapted for the purposes intended. The cultivator is stated to be a good instrument for opening a furrow, for planting, as well as for the culture of corn, the ox-yoke is reported to be the one always used in Spain; and the hand-drill seems to be well calculated for sowing almost any kind of seed or grain upon land nicely prepared and pulverized. They recommend the trial of these instruments, and also of the cutting-box. The model of a coulter was also exhibited by Mr. Taliaferro, which seems to deserve a trial; but, in this case, as well as the others, the committee had no opportunity of testing its value.

WM. P. TAYLOR, *Chairman.*

The committee on flour, report—that they have examined the flour exhibited to them, and award the premium to R. T. Willis, of Orange.

HUGH SCOTT, *Chairman.*

Essays on agriculture were read by Dr. Wm. Browne, Wm. P. Taylor, and Robert B. Semple: when the society adjourned, to meet to-morrow at 10, A. M.

Saturday morning, Nov. 10.

At 10, A. M. the president took the chair. On motion of Wm. P. Taylor, JOHN S. CALDWELL was unanimously elected secretary and treasurer of this society. The following resolution was adopted: Whereas large amounts still remain due upon the books of this society—

Resolved, That the treasurer be directed to draw off the accounts of delinquent subscribers, and forward them to the deputy sheriffs of the counties in which they respectively reside for collection, allowing such commission as he may deem proper, not exceeding 20 per cent.

After the adoption of other resolutions of a private character, the society adjourned to the town hall to witness the exhibition of domestic manufactures, and to hear the president's annual address.

Afternoon session.

The society met at 3 P. M., the president in the chair, when the report of the committee appointed to examine domestic manufactures was read.

The committee reported that they had discharged the duties assigned them. They regret that the exhibition has been more indifferent than they have ever before seen it. There were fewer articles exhibited, though those that were shown, were of very superior quality. Among those deserving a premium, were the following:

For the best yarn counterpane, L. V. Stevens,	$3
For the best cotton ditto, Mrs. Wm. Rothrock,	3
For the best yarn stockings, Miss Tally,	1
A discretionary premium was awarded to Mrs. Hunter, for sewing silk and a pair of silk stockings, manufactured by herself, of	5
A discretionary premium to Miss A. E. Eliason, for silk stockings,	2
For rug, to Mrs. Wm. Pollock,	3
Mrs. Stevens, for Scotch plaid,	3

The committee examined a specimen of brooms, from the factory of Hunt & Browne, and think them superior to any thing of the kind they have ever seen, and justly entitled to a premium.

The domestics exhibited by the woollens factory of Fredericksburg are recommended as a useful and superior article for servants' clothing.

A carpet was exhibited by Mrs. John Hart, of Fauquier, manufactured of cotton. It was very superior of its kind; but as it was not exhibited for a premium, the committee therefore declined to award one.

The committee further report—that they have examined three suits of clothes; all of which were of superior quality, and displayed great skill in their manufacture. Whilst the suit worn by Mr. Eliason commanded the admiration of the committee, yet, they being dyed and dressed at the fulling mill, placed them in the esteem of the committee out of the rules of the society. The committee, therefore, award the premium to Joseph Sanford.

WM. C. J. ROTHROCK, *Chairman.*

The committee on butter, award the premium to Miss Nelly Lee, of Orange.

WM. JACKSON, *Chairman.*

A communication was read from Turner H. Ramsey, tendering an annuity of $15 towards the payment of premiums, additional to his annual fee as member of this society. The offer of Mr. Ramsey, was accepted, and the thanks of the society tendered him.

On motion of George Hamilton,

Resolved, That the secretary cause to be procured, a book, in which each individual now a member, or who hereafter may become one, shall register his own name, the date of his becoming a member, and the county in which he resides.

On motion of Wm. P. Taylor,

Resolved, That the annual subscription of each member of this society, on and after the next fall meeting, be $3.

On motion of James M. Garnett,

Resolved, That the Agricultural Essays of Messrs. Browne, Taylor, and Semple, read to this society yesterday, be forwarded to the Farmers' Register, with the request of the society that they be published in that journal.

Resolved, That the proceedings of this society, with the president's address, be published in the Herald and Arena, of Fredericksburg, and the Farmers' Register.

The thanks of the society were, on motion, tendered to the president and secretary—and the society adjourned.

JAMES M. GARNETT, *Pres't.*

R. B. SEMPLE,
Sec'ry. & Treas'r. pro tem.

From a Foreign Journal.

THE MOON.

In the last number of the Monthly Chronicle, we find some statements drawn from astronomical observations, which must be quite new to those who have hitherto supposed this planet to be inhabited by animal beings. The most powerful telescope ever yet constructed does not enable us to see distinctly an object whose visual magnitude is so small as one second, corresponding to a mile on the surface of the moon. It therefore follows that an object, say a town on the moon, measuring a mile across in each direction, would be too small to be discerned by any aid which telescopes have yet supplied. "If the moon be examined," says the writer, "for any length of time with the aid of the most ordinary telescopes, the observer cannot fail to be struck with the unalterable character of the outlines of light and shade upon the surface. These are distinct and well defined, that they may be delineated with great exactness;

and a map exhibiting their appearance at any one time will continue at all times to exhibit that appearance with the same fidelity and precision."

The first inference which he draws from this circumstance is, that the same side of the moon is always turned toward us, and as she turns round on her own axis, in about twenty-seven days and eight hours, the Selenites, or inhabitants of the moon, as denominated from the Greek word 'moon,' must have 328 hours daylight, followed by 328 hours night. The next is, that there are no clouds suspended around her; and a third inference, drawn from other data, is, that there are no indications whatever of seas and water in the moon; and if there is any atmosphere at all, it must be a thousand times less dense than that of the earth. It would require a perfect air pump to produce such a degree of rarefaction under a receiver, and such an atmosphere would, as far as regards all the phenomena of animal and vegetable life, be a vacuum. The following description gives a frightful picture of this silvery orb of night:

"The character of the entire surface of the moon, so far as telescopic power has made it known to us, is just what might have been expected in a world deprived of air and water, and of the tribe of beings to whose life these are necessary. This most inhospitable planet exhibits a wide waste of surface, diversified by nothing but its lofty mountains and cavernous valleys. Chains of mountains and insulated hills are spread over every part of the surface, and lift their menacing and precipitous sides frequently to the height of five perpendicular miles. In many places huge masses of earth spring directly from the plain and carry their peaked summits to the altitude of twenty thousand feet. Nor is the extent of the base of these stupendous eminences less astounding that their heights. The diameters of the bases of several detached hills of this kind, which measure five miles in height, vary from twenty-four to forty-six miles.

"But the circumstance which deprives the moon's surface of every trace of analogy with that of the earth, is the enormous circular cavities which are found in almost every part of it. Some of these caverns are four miles in depth and forty miles in diameter. Their edge is generally defended by a high natural wall. Frequently a conical mountain rises to a considerable height from the bottom of this dark circular hole. The top of this cone is rendered visible when the rays of the sun fall directly into the cavern. This internal conicle mountain has sometimes a circular cavity in its apex like the crater of a volcano.

"The provision which gives to the several planets the grateful returns of the seasons is denied to the moon, and accordingly not a trace can be discovered on her surface of the slightest variation which can be ascribed to change of season.

"If, then, the moon be the habitation of living things, they must be constituted with functions very different from all those which characterize the animal and vegetable kingdoms of the earth. In the absence of atmosphere, the Selenites cannot of course be respiratory animals. Sound, which depends on air for its production and conveyance, there can be none. Speech and hearing would therefore be useless faculties.

"No azure firmament offers its mild tint to the eye of the Selenite. The blue of our sky is the proper color of our atmosphere. In the absence of an atmosphere, the firmament of the moon is one eternal and unvaried black, through which the glowing orb of the sun holds its solitary way, vainly endeavoring to diffuse brightness beyond the edge of his own disc. On the arid and ungrateful waste beneath, his genial rays fall in vain —no atmosphere is present to collect, retain, and diffuse their warmth; and if they fail to sustain animal and vegetable life on the summits of our Alps and Andes, merely because of the rarefied state of the atmosphere at those heights, how much more ineffectual must they be in the absence of any atmosphere whatever.

"Seeng, then, that while we find on all the planets the same provisions to fit them for the dwelling places of creatures like ourselves, and those provisions supplied in the same manner, and to the same extent; and, on the contrary, finding all of those arrangements, without one exception, denied to the moon, we must, in the absence of any direct evidence on this question, come to the conclusion that our satellite is a barren uninhabited waste, playing doubtless some necessary part in the creation, but not the higher one assigned to the earth and planets; that it is, in fine, a desert rock, resting its head in the wide ocean of space, unappropriated to and unfitted for the resting place of any living thing.

For the Farmers' Register.

LEGISLATIVE AID TO AGRICULTURE.

No. I.

Two years have now nearly passed since the advocates for legislative aid being given to agricultural improvement have ceased their previous and earnest efforts for that great object. It was not that the object sought had lost any value in their estimation; or that they did not still think that its attainment was imperiously required for the resuscitation and continued prosperity of the great and general interests of Virginia. But their arguments and petitions had met with no favor from the legislature; and, indeed, scarcely any response, or appearance of hearty concurrence, from the great body of the agriculturists of the country. Under such discouraging circumstances, the most ardent and zealous advocates for governmental aid to agriculture, had no choice but to cease their efforts.

But circumstances of recent occurrence have served to rekindle hope, and to urge to renewed efforts. The commercial convention, which lately held its session in Norfolk, included this subject among the necessary elements of the commercial prosperity of the commonwealth; and *unanimously* approved the report and resolution of the committee on this subject, (which was published in the last No. of the Farmers' Register, p. 570,) and directed committees to present and sustain those views before the then approaching sessions of the legislatures of Virginia and North Carolina. The highly respectable body which directed there proceedings, though called together, and acting mainly, to aid the resuscitation of commerce, was nevertheless composed principally of delegates from the country, who belonged exclusively to the agricultural interest. And the delegates from the towns, even if not directly or exclusively members of the agricultural interest, were sufficiently identified with it to render their unanimous decision on this question a strong indication of the opinion of the intelligent community.

Under these favorable auspices, then, this all-important subject will again be brought before the legislature of Virginia; and all private individuals who have heretofore labored for the object, and all who heartily wish its promotion, are called upon to lend their countenance and aid to the recommendation of the convention. For the purpose of aiding in this work, it is the design of the writer to present his views at some length, on the proper subjects for legislative action, in aid of agricultural improvement. In these views, there may, perhaps, be nothing which has not already been stated in the earlier volumes of this work. But without claiming the merit of originality, for the present article, he hopes to be useful if merely confining his labor to digesting, and presenting at one view, the opinions and arguments which are scattered so widely, that no reader, perhaps, remembers, or will take the trouble to refer to them elsewhere.

Before entering upon the consideration of any particular means of aid to agricultural improvement, it is proper to premise that all which are sought, all which are considered legitimate and proper, to be afforded by government, will come under a single head—that of INSTRUCTION, or the collecting and communicating knowledge on agriculture. All means which will aid instruction are good, however they may differ in their degrees of value; and all which will not aid instruction, will be either useless or injurious.

First, let us consider the *right* of the legislature of Virginia, to aid agricultural instruction, and the *expediency* of the exercise.

It is not the legal or constitutional right or power of the legislature, that any one will question. On that head, there is no doubt. The denial of right will only be made on the ground of its being an unsuitable, improper, and unnecessary exercise of legislation. It is on this more extended ground that the question of right will be considered.

Adam Smith, the great head of the free-trade school of political economists, the highest, and deservedly the most venerated authority for restraining (on the score of policy,) all useless legislation, limits the proper action of government to three subjects only. These are 1st. the maintaining of justice between the individuals of the nation governed, and between the nation and foreign powers; 2ndly, the construction or facilitating of great works of acknowledged value, but which are too extensive or costly, for private individuals to execute, either singly, or by agreement between many; 3rdly, the providing for necessary education of the people, in such cases as there are either no sufficient means, or no sufficient demand on the part of the people to secure the supply. It will be admitted that these limitations are abundantly close, to cut off all improper subjects of legislation; though neither these, nor any general limitations, can prevent the improper treatment of legitimate and proper subjects. In the propriety of these close restrictions we fully concur, and claim nothing for agriculture which cannot be clearly deduced from, and be found authorized by these strict rules.

Few, if any, legislators, or private individuals, will deny that it is a right and duty of government to give proper and judicious aid to the general, or literary education of the people, in such cases as the object cannot be attained without the interference of government. Where private and general demand and supply are so established, that such interference or aid is not wanted, then, as in all other cases, the free-trade doctrine correctly and fully applies, and any interference of government would not only be useless, but absolutely hurtful to the cause of education. Thus, the advantages of ordinary schools for teaching the English and even the Latin and Greek languages, are sufficiently appreciated in this country to insure a supply of schools and of teachers; and the government is not only, therefore, not required to furnish such schools, and to pay their teachers, but would certainly do harm to education by every such attempt. But for the highest branches of scientific instruction for those who have by their own efforts gained the necessary previous knowledge, there is not sufficient appreciation, or demand, to ensure a supply of instruction, or of persons competent to instruct; and neither do the most ignorant (in this or any country,) enough prize the elements of the lowest instruction to be willing to pay the smallest pittance for having their children taught. Therefore our government properly and wisely (in design at least, if not in the mode of execution,) interferes in both these cases, and aids, or attempts to aid, both the highest and the lowest branches of education and learning. The necessity of education to all classes is justly considered in regard to the general weal, and not as conferring a boon or benefit on each individual aided. It is highly important to the public interest and public morals, that no citizen should be entirely ignorant of letters; and the state endeavors (though but to little purpose,) by an enormous annual expenditure, to prevent as much as possible that great national evil. It is also highly important that there should be the means afforded within the borders of Virginia, for acquiring the higher branches of scientific education—without any benefit of which a community would soon sink into brutish ignorance—and which, without such means at home, would be gained but by very few, and those, at great expense, and by going abroad. To prevent this great evil, this incalculable waste of money and of intellectual value, the state wisely offers to all those who will prepare themselves at a great previous expense of their own, the means of making themselves still more useful and valuable as members of the commonwealth. These are the true principles and proper grounds for the aid of education by the government. The education conferred may operate very beneficially and profitably to the individual so instructed; but it is not with that view, that it is, or ought to be given, but to render the individual of greater value to his country.

These views are as correctly applied to agriculture as to literary and scientific education; but in a far stronger manner, both as to the existing deficiency of means for gaining knowledge, the great necessity for such means, and the certainty that every gain of profit and income made in consequence of such aid, will also be a gain and profit to the commonwealth. Before proceeding to the consideration of the proper and best means of furnishing agricultural instruction and knowledge, we beg leave to offer an illustration of the particular position just mentioned. The subject taken for illustration, is chosen, not by any means because it is one of the most important to agriculture, and the commonwealth's interests, but, because it is one which now excites much curiosity, and is one on which there is as yet among us but little knowledge, and no practical experience.

Thousands of the cultivators of Virginia have been recently and violently excited by the speculating mania which has raised the price of mulberry twigs to more than their weight in silver, and design next year to commence the cultivation of the mulberry tree, as largely as circumstances permit, with a view to profit from the expected and extensive culture of silk in this country. Many of these persons are directed by sound views, and design to begin and prosecute a regular, and, as we fully believe, when understood, a profitable business. Many others, it is feared, are impelled merely by a wild and groundless spirit of speculation, in sales of plants. But whatever may be the motives, and whether the wise or the unwise may preponderate, and whatever may be the amount of ultimate profit from the new business of silk culture, *this is certain*, that many thousands of dollars, perhaps hundreds of thousands, will be risked, and wasted, in untried experiments and processes, of which all engaged are entirely ignorant; and it will follow, of course, even though the final results may be profitable to individuals, and highly valuable to the state, still, that a large proportion of all the first enormous outlay of expense, will be sacrificed and lost, because of the inexperience and ignorance of the adventurers. Now, if the state had paid the expense of the first experiment, and had spared no pains and cost to have the trial fairly and fully made, by putting to work the best knowledge and skill in the business, with the best means to operate with, then this expenditure would have served to prevent a hundred fold greater by individuals, and have turned to profit all that will now run to loss. If a mulberry nursery and cocoonry had been established at the public expense, upon the best known plan, and making trial of every supposed improvement, then the problem of the amount of products and of profits would have been already placed beyond question. Such an establishment would also have furnished the best possible school of practical instruction in the business. Every individual who was inclined to commence it, would visit it, and see, not the mere first trials of novices, but all the processes, and the general procedure, of the best and oldest establishments of Europe, as well as trials of every newly proposed improvement. The income of the cocoonry, perhaps, would have paid the greater part of the expense—possibly the whole; but even if the excess of expenditure over income had been $10,000, it would still have operated as a great pecuniary gain to the whole commonwealth, as well as to the numerous individual adventurers. And though this subject, taken for illustration, is a novel and peculiarly strong case of general ignorance, great risks, and consequently great losses, which the state might have prevented at little cost, and to great ultimate profit, yet the like application might be made to various separate and important branches of agricultural industry, as well as to general instruction and diffusion of knowledge on the whole subject.

If it may be permitted to pursue this illustration still farther, it may be affirmed, that if such a silk business and school had been established in Virginia three years ago, among the other lights derived, the peculiar value of the morus multicaulis, or Chinese mulberry, would have been fully ascertained, and its culture generally diffused throughout the state; and consequently the great enhancement of its market price, and the mad speculations founded thereon, either would never have existed, or, if so enhanced, the sales would have brought millions of dollars to the state, for products which cost almost nothing, instead of draining a vast amount from this state to cultivators abroad.

So far, as to the need for agricultural instruction in general, and its value to all who will profit by its being provided. But even if all this be fully admitted, there will then still be opposed the objection of demagogues and popularity-seekers, "that it is unjust to tax the whole population, for the benefit of a part." Though this miserable substitute for argument is brought to oppose every new proposition for beneficial improvement, it never raises its head in the same cause after being once successfully resisted. In truth, there is scarcely a legislative act of any kind, or tax or requisition, which may not as much be said to be a charge to the many for the use or benefit, or demand, of a few, as would be pecuniary grants for the improvement of agriculture in an agricultural community. The complaint is as absurd and as groundless, as if an individual complained of the injustice of his being taxed to support criminal justice, because he was neither a judge to be honored and paid, nor a felon to be hung. But of all such charges of injustice, that against agricultural aids would have the least color. The agricultural interest in Virginia is so extended as almost to be identified with the community in general—and it is certain, that the former cannot possibly be benefited, except to the benefit of the whole commonwealth. The few, who have no direct or immediate interest in agriculture, are indirectly and remotely, but yet considerably interested; and any burden imposed on them in common with all other citizens, for improving agricultural products, would in a far greater degree improve their interest in agriculture, indirect or remote as it may be.

It still might be contended, (at least by court-yard and muster-ground orators, and office-seekers,) that some agriculturists would derive all the benefits, while others would merely share in bearing the cost of the system. This could scarcely happen upon a proper system of instruction, except to those who would blindly and obstinately continue to reject all light and knowledge; and for such cases it would be waste of all effort to attempt to furnish either aid or remedy.

Next, let us consider the peculiar deficiency and want of agricultural education or instruction.

Agriculture, as a science, has been less investigated by competent inquirers, and is less understood, than any others in general use, and deemed important. As an art, it stands still lower; as the necessary processes, even when judiciously planned and directed, are never *all* executed properly on the farm of the most skilful cultivator; and in most cases, *none* are executed well, and generally all very imperfectly. What would have been the condition of the now admirable and profitable cotton factories of Virginia, if few of their processes were planned, and none executed correctly—if none of the machinery was of the best kind, or in good order, and none of the laborers had skill in their departments? Add to this supposition, that the proprietors, constructors, superintendents and operatives had never seen any better works, and the supposed case is then precisely parallel to agricultural operations in general, and especially to those of Virginia. Every one knows that in the manufacturing business, it is essential to profitable results, that every material element, of general plan, of construction, and of all the daily operations, should be of the best kind known; and no persons would be so foolish and regardless of their interest, as to attempt the business without first buying, at any price, all the benefit of the experience and acquired knowledge of others on the subject, and endeavoring to employ agents and operatives who should be as skilful as those of any other factories. And without such precaution and measures of security, every one would predict that the business would soon come to ruin. Yet the course which all would condemn in this case, as absurd and hopeless, and which would not be adopted by the most careless and improvident proprietors, is precisely like the general, almost universal, condition of agricultural operations. How can it be otherwise? The proprietor usually has either wrong rules of action, or none—the superintendent, or immediate director, is seldom otherwise than profoundly ignorant of the science, if not also of the art of agriculture—the implements are defective—and the laborers unskilful in their use. Yet, under all such defects, which would speedily make any other business bankrupt, agriculture in Virginia, in general, is as safe and profitable an employment of capital and labor, as any other; which alone suffices to prove that it would be very far more profitable and productive of wealth, both to the undertakers and to the commonwealth, if it were possible to add to the productive power all that is offered by knowledge, and all the lights of the experience of the better instructed.

According to the wretchedly defective mode of education in this country, even the sons of the best farmers, and who may be designed to pursue their fathers' business, are debarred from all knowledge of it, until they commence, as proprietors, to bear the customary losses of ignorance and inexperience. If the father is wealthy, the son is kept at school and college until arrived at manhood; and then if he becomes a farmer, he is almost as ignorant of the business as if he had never seen it in operation. Every one, rich or poor, alike commences farming as head of the establishment, utterly ignorant; and the far greater number remain through life, without being much more enlightened. The first losses, of course, fall on the particular individuals who are so illy qualified as farmers; but their loss is also the loss of the whole community; and indeed no other individual, however little connected with agriculture, can miss paying some share of so enormous and permanent a drain from the wealth of the nation.

Having attempted to depict and expose the existing evil, we will now proceed to consider the different means for remedy; the means by which, it is believed, the knowledge of agriculture would be widely diffused and greatly augmented, and its improvement and its profits be proportionately advanced. The institutions which are deemed the best to advance the great object in view would be the following; which might be adopted altogether, or but in part, according to the intention of the legislature to operate either on a large or a small scale.

1. A state Board of Agriculture.
2. County or district Agricultural Societies, to be represented either in the Board of Agriculture, or in a general or State Agricultural Society.
3. A farm for experiments, which will also be a school for practical instruction in agriculture, in each of the four grand divisions of Virginia.
4. Surveys and reports of the actual agricultural condition of the different districts of Virginia.
5. A professorship of scientific agriculture, and its kindred sciences.
6. The establishment of cheap periodical or other publications on agriculture, for general circulation; and cheap school books to supply every pupil reading English; and of which the subjects should relate to agriculture, the mechanic arts, or something useful and instructive in domestic economy, or the ordinary business of the future lives of the pupils.
7. The facilitating and encouragement of agricultural apprenticeships, or practical and manual instruction, on the farms and under the direction of some of the most intelligent and successful cultivators.

Let not the reader, even if a legislator, be startled at the length of this list. It may be limited as closely as may be desired; and one measure alone, and that the cheapest of all, may be carried into useful operation, even if all the others be postponed or rejected. But as we are not legislating, but merely suggesting subjects for legislation, each and all of the measures most likely to aid the improvement of agriculture will be here considered, at more or less length, in proportion to their supposed relative value and efficiency.

Board of Agriculture.

The institution and proper working of a board of agriculture would be the most simple, cheap, and at the same time the most certainly efficacious, of all the means proposed in aid of agricultural improvement. If operating alone, it might produce results much less important than other means; but it could not fail to do some good, and could not possibly do any harm, beyond the small annual cost of the institution.

The best manner of constituting the board, or of selecting the members, would depend upon whether this measure stood alone, or in connexion with agricultural societies. In the former case, the appointment should be by the executive branch of the government; in the latter case, it might be well to give the societies, or their delegates, the power of appointing some of the members of the board. In either case the number of members need not exceed two or at most three, from each of the four grand divisions of the state, or from eight to twelve members in all; and also, howsoever chosen, it may be presumed that the members would be among the most intelligent and best farmers of the state.

A body thus constituted, could, by proper inquiry and examination, draw forth from every region, reports of the condition, the existing advantages and good practices, and improvements in agriculture, the knowledge of which is confined to the narrow limits of their respective small neighborhoods, and which therefore, in each particular case, is hidden from, unknown, and useless to the country in general. Though information so gathered might be but general, loose, and but little satisfactory, compared to what better means might elicit, still, what was gained would serve to sharpen curiosity, and direct inquiry to the sources of more full explanation and instruction.

But a more important operation of such a board would be to examine well and learn the wants of agriculture, which legislative aid could provide for, and remedy; and to report the evils found, and recommend the specific means for relief. The opinions and recommendations of such a body, could not fail to be heard with respect; and there would be ground for hope, that thus, cautiously and gradually, the best of other means would be devised for doing the greatest possible service to agriculture, and consequently to the country at large. The investigations, the experience, the judgment, of the members of a board of agriculture would serve to settle, in the most satisfactory manner, the comparative claims and merits of all other means for aid and improvement, such as the remaining subjects which it is proposed here to examine in succession.

The board should have permission to recommend any thing, but power to enact or establish nothing, unless by special order of the government. Thus it might induce much future good to be done, and it could, directly, do no harm, nor commit the legislature to any undertaking whatever.

The main recommendation (as we fear it may be deemed) of a board of agriculture must not be forgotten—the *cheapness* of the establishment. The annual sessions need not exceed two weeks in length; and the whole cost need not exceed fifteen hundred or at most two thousand dollars.

COMMERCIAL CONVENTION.—CONTINUED.

Report on Direct Trade and Internal Police.

The committee, appointed to report on the subject of a direct trade with foreign nations; and to suggest what legislation may be necessary on the subject, beg leave to report:—

That they find it difficult to illustrate the magnitude of the evils resulting from a system of indirect trade, and will remark, that a full review of the past history of Virginia would better elucidate the subject, than any argument which could be urged by them; but the time of the committee will not allow them to treat this topic as it deserves.

That Virginia has once enjoyed a direct trade, and all the benefits attendant upon it, all will admit. Scarcely a town in the tide-water region but shared the direct trade to a considerable extent, while at present our most important marts are tributaries to the north to nearly their whole amount of business. When they enjoyed the direct trade, our cities, towns, and country were alike prosperous, and emigration did not desolate our land. With the loss of that trade, our small towns fell to ruin, our cities were made desolate, and our population have been fleeing from our borders; while those towns which have obtained our business in other states have grown rich upon our resources, and have increased in wealth, and numbers proportionate to our decline. During the state of colonial dependence, the several colonies were prosperous in proportion to the amount of their surplus production, and their means of consumption, but the reverse is now the case, those who raise the greater portion of the exports and consume most of the imports deriving no profit, but sustaining a heavy loss from the operation.

In spite of the loss and injury sustained by emigration and our perverted system of trade, agriculture has advanced very considerably, and even the tide-water section yields a greater surplus than in the season of the greatest commercial prosperity. But even in this respect, we are not as prosperous as those states that enjoy a direct trade, although their natural advantages are far inferior to ours. This is painfully manifest from the fact that in 1836 the whole assessment value of the lands, houses, &c. &c. of Virginia was but $207,000,-000, a sum less than the assessment value of the real estate in the single city of New York for the same year. Your committee are unable to state the value of the personal estate of Virginia for that year, but perceive that the real and personal estate of the city of New York was over $309,-000,000! The humiliating fact also occurs to your committee, that the value of all our lands and improvements, including valuable city lots, &c. does not exceed on an average, five dollars and ten cents per acre, a price which it is confidently believed might be realised to the United States, were Virginia a territory, and a wilderness, and her lands offered at auction on a liberal credit! Now, if it be considered, that the citizens of other states enjoy almost the entire benefit derived from all the profitable branches of our business, we see strong inducements for our most enterprising citizens to leave us and locate in other states with a view of reaping the profits of that business which ought to be enjoyed at home, and thus to lend their unwilling aid to our farther impoverishment. Experience too clearly proves that there is nothing in our agricultural prospects to stay the progress of emigration in the present state of things; for in all the states, north and west of Virginia, and in all the countries of Europe, the labor bestowed on lands in the way of improvements, adds to their value, and to the general wealth of a state, while with us, if such a hope were entertained, the past would afford a melancholy refutation of its justice. If we look to Virginia and the southern states, and then to the states of Europe, the contrast will be striking. All foreign states enjoy a direct trade, and furnish their retail dealers within their own borders, thereby giving to their own cities and people all the profits arising from negotiating exchanges and furnishing supplies—which is a main source of commercial power placed beyond our reach, so long as we allow those foreign to the jurisdiction of Virginia to pocket the profits of our trade. It is believed that, if Virginia were to convey to the northern ports the value of $5,-000,000, as a gratuity, to be substracted from her means and added to the capital of the north, and yet prosecute a direct trade in foreign and domestic supplies through the medium of our own ports to the extent of the remainder of her resources, she could be far more prosperous than at present. It is evident, that the loss of Virginia, in consequence of the indirect trade, exceeds the profit of the northern merchants who monopolize our business, inasmuch as not only the same profit, which would accrue to the southern importer, must be paid abroad, but the incidental expenses of freight, insurance, travel, &c. must also be added to our detriment.

It appears to your committee, from the best evidences in their possession, that the profits paid to northern cities on merchandise by Virginia, North Carolina, South Carolina, and Georgia, from 1816 to 1836, a period of twenty years, were greater in amount than the public debt of the United States which was liquidated in that time, amounting to $170,000,000, with interest thereon; and had the south retained the direct trade, they believe that the increased value of property in her cities and towns for that period would have nearly reached a similar amount; and, as it is obvious that rich and flourishing cities enhance the value of the property of the entire states to which they belong, every foot of southern soil would have been enriched by that process. It may here be stated, that Virginia and North Carolina do not even enjoy a direct trade with New England, as the greater part of the manufactures and products of that section, which are consumed in the South, are obtained from New York, Philadelphia, or Baltimore, and come to us well laden with the charges of the indirect route. Looking at our present commercial policy in all its results, your committee are constrained to adopt the opinion, that such another instance of self-immolation is not to be found in the annals of the world.

They beg leave further to illustrate the benefit of a direct trade, by stating the fact, that in all civilized states, which enjoy their own business to a respectable amount, compared with their resources, more than a moiety of the wealth will be found to be located in their marts of commerce and business. In all the states north of us this principle will apply with full force. It is true that the trade of many of them is of late becoming indirect, and their present ratio of increase of capital is not as uniform as formerly; yet at this time in Maine, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, Pennsylvania, Delaware and Maryland, either under a system of fair taxation may draw more revenue from its marts of commerce and business than from all other portions of its territory. But this is not the case with Virginia, as the assessment value in her four principal seaports is but about $19,000,000, which is but about one-eleventh part of the value of real property in the state, which is as follows:

	Value of Houses.	*Val. of Lands.*	*Aggregate.*
Richmond,	2,639,344	8,001,540 82	10,640,884 82
Norfolk,	2,188,625	2,704,430	4,893,055
Petersburg,	1,921,494	866,011	2,787,505
Fredericksburg,	233,221	832,897	1,066,118
	$6,982,674	12,404,878	19,387,563 82

We find again that in many of the states of Europe from one third to one half of the population draw their subsistence from the business marts; and in the Atlantic states about one-fifth of the population are thus located; but Virginia is very deficient in her quota, she having but about 49,000 souls in all her towns which have over 5,000 each, (which includes the enterprising but neglected towns of Portsmouth and Wheeling,) our whole population being estimated at 1,300,000 souls; and therefore, whilst the Atlantic states, as a whole, have a business population in the proportion of one to four, Virginia has but about one to twenty-five, and while our agricultural business is capable of sustaining by this ratio, a population in our marts of business of over three hundred thousand souls! It is therefore very manifest that we sustain a much larger business population in other states than in our own, and that the value of real estate in the cities of other states, is great in proportion to the amount in consequence of business which they derive from us. The value of country property in other states is also augmented by the increased wealth and population of their cities, which we sustain to the neglect and ruin of our own.

Your committee find that the British colonies in North America are in an enviable condition compared with Virginia. The Canadas, with an aggregate population less than Virginia, sustain a population in their business marts as great as Virginia, North Carolina and Georgia together, and they have few or no mechanics or artizans, and they look to the mother country for even horse shoes, and horse shoe nails, and the most common articles usually made at home.

In the island of Cuba (which is as convenient to New York, as the state of Alabama,) we find that the whole population is less than in Virginia —and yet we find that its numbers about triple our number of business population, and that the wealth and revenues of her ports is greater than from all her interior, and it is evident that her retail dealers procure their supplies in her own marts.

The same is the case in reference to Jamaica, and it appears evident that if all the retail dealers in those islands were to obtain their supplies in New York, that their present flourishing and prosperous ports would soon be reduced to the condition of our Cobham, York Town, Tappahannock, or City Point, and the destruction of those ports would be ruinous alike to the prosperity and security of the inhabitants of those islands.

Your committee find that there is no state in Europe which has not made a greater proportionate increase in population and wealth compared with their former condition, than Virginia, and the same comparison will apply with full force in reference to all our northern states.

Your committee are of the opinion that the concentration of the trade of Virginia in her own ports for a single year, with the prospect of its continuance to an amount equal to furnishing the supply for the consumption of the people of the state, would produce an increased value of property in that short period to the amount of not less than fifty millions of dollars. This it is admitted looks extravagant, but it must be borne in mind that property is valuable in proportion to the useful or beneficial purposes to which it may be applied. If the country dealers and planters would purchase the amount in our ports which they now purchase in those of other states, it would be found that our present state of agricultural strength would require and support a seaport population of over 200,000 souls. This would triple the surface of our towns, and more than quadruple the actual value of the lands therein. Buildings which are now being erected in other states upon the profits of our business would start with magic enterprise with us; and the money paid for their materials and construction would remain the property of our citizens. Lands in the vicinity of our towns would enhance in value, for lumber and fuel, while agriculture would find a new stimulus in furnishing productions to those who now subsist wholly at our expense, and to the profit of others.

If time would permit, your committee would attempt to demonstrate that the consumption of the state of Virginia, of commmodities, the produce and manufacture of which is foreign to her jurisdiction, is as great as that of the whole United States was, so lately as the year 1790; and will leave to this convention and to history to answer, whether the trade of these United States was considered of such importance as to induce national efforts (which have been successful) to enable the United States as a whole to enjoy equal and reciprocal commerce; and to inquire, is not an amount of trade which was worthy of the concerted action of the United States in 1790, at least worthy of a united and patriotic effort of the people of Virginia in 1838?

Your committee assume that the mercantile profits of export commerce from the state of Virginia is about one-eighth of the profit of the import, including with the import however the furnishing all the varied supplies for the interior. Were we therefore to export our whole productions and furnish at first hands none of our supplies, we should enjoy but one-ninth part of the profits of our business. If this position be correct, it behooves us to place ourselves in the possession of the business of furnishing the tide-water region of our state before we mature large schemes of internal improvement, to confer more trade at our cost on our rivals whom we now see possessed of that which nature designed for us, and of which we can only re-possess ourselves through that reserved sovereignty, which it is our right to exercise by a legal regulation of our internal police.

Your committee find that the evils of an indirect trade are not exclusively felt by the states of Virginia and North Carolina, but by many other states; and when they look at its result, and observe that it is verging towards a commercial consolidation of the whole pecuniary energies of this great confederacy in a single city, they cannot contemplate our condition, but with dismay; more especially when we consider that we pay our rivals one hundred dollars for what costs them about seventy dollars on the average of our transactions; and this is the boon which we obtain in going from home, not to buy supplies, but to buy credit in obtaining them.

On reference to the history of trade in the old world, and of its concentration, your committee are constrained to adopt the opinion, that it is not, nor has it ever been, absolutely free. It has, indeed, ever been subject to legal direction in all civilized societies, and in those not civilized there is but little or no trade to receive the fostering aid and protection of legislation. All the states of the old world have at least one point of commercial monopoly; and it is admitted by political economists, that the trade of an empire will find a point of supremacy within itself for all its large business; and that the smaller trade will, and should be subordinate to such concentration, which is the effect of legislative provision.

This result must be expected under any consolidated government, and it is evident that the trade is subordinate to law, or the seats of business in each nation would not, in all cases, be within herself.

It is urged by many, however, that under our federal system, we must submit to what they call the "inevitable law of trade," which they say is that of consolidation of all commerce at a single point; and such has been the perpetual tendency of the business of the United States for the last forty years. It is also admitted, that this may have been the result of governmental action; but if it be so, it has not been by the design of those who have administered our affairs, but the fault of the people of the states, who have permitted this concentration. It must be observed, that our government is not one of consolidation, inasmuch as the federal government regulates all foreign business, whilst that of each state may regulate its internal concerns as its wisdom may direct. It does not, therefore, appear to your committee, that the trade of the United States will necessarily remain consolidated any longer than those acquiesce in such a state of things, who are impoverished by its consequences. That there is abundant power over this subject, reserved to each state, is evident on reference to the fundamental principles of our government, and to the causes which led to the formation of the constitution of the United States.

That your committee may be sustained in the premises, they present herewith the opinion of that eminent jurist, James Kent, formerly chancellor of the state of New York, which they trust will be received as good authority, sanctioned, as it is, in its doctrines, by the decisions by Chief Justice Marshall, in the case of Brown vs. The State of Maryland, and Gibbons vs. Ogden.

"CHANCELLOR KENT'S OPINION.

Questions.

1. Is the law of the legislature of Massachusetts, passed the 19th of April, 1838, and entitled "an act to regulate the sale of spirituous liquors, constitutional, and consistent with the revenue laws of the United States?

2. In what manner can a violation of the license laws of Massachusetts be carried into the supreme court of the United States?

These two questions have been submitted to me, as counsel, for my opinion thereon, by a gentleman of the city of Boston, who considers himself interested in the inquiry.

Opinion.

1. The act alluded to, declares, that "no licensed innholder, retailer, common victualler or other person, except licensed apothecaries, physicians and others, who may sell spirituous liquors to be used in the arts, or for medical purposes only, shall sell any brandy, rum, or other spirituous liquors, or any mixed liquor, part of which is spirituous, in a less quantity than fifteen gallons, and that to be delivered and carried away all at one time, under a penalty, from \$10 to \$20 for each offence."

The former statute in relation to this subject, of the 20th of April, 1837, declared that no licensed innholder or other person should sell any intoxicating liquor on Sunday, under the penalty of $20; and that if any person should have been three times convicted of a breach of the act, *or of the 47th chapter of the Revised Statutes*, he should be liable to severe specified penalties and punishment. It is to be observed, that the 47th chapter referred to, has twenty-nine sections, and several distinct offences and penalties are declared in it, all relative to the regulation of licensed and selling of spirituous liquors.

I have attentively considered the first question, and I have satisfied myself that the statute of last April, therein mentioned, is not repugnant to the constitution or laws of the United States. I am of opinion, that the statute in question relates to the internal police and government of the commonwealth of Massachusetts, and that it was competent for the legislature to pass it. The government and laws of the United States have no concern with the internal regulations of the states. These regulations belong exclusively to the power and authority of the state governments, and they may pass what sumptuary laws they please in restraint of the interior commerce of the state, and of the manners and habits of the residents therein. All such regulations, however stern they may be, rest entirely on the wisdom and sense of expediency and policy of the local legislature, provided they be consistent with the constitution of the state.

In the case of *Brown vs. The State of Maryland*, (12 Wheaton, 419,) the validity of a state law, in restraint of the importation laws and foreign commerce of the United States, was fully discussed and considered. The doctrine of that case was, that a state legislature could not impose a tax on goods imported, *while the goods were in the hands of the importer, and in bulk*, and that a right to import the article under the laws of congress, and a payment of the duty, carried with it a right to sell it, free of any previous charge, or duty, or tax thereon laid by the state while in possession of the importer. But the case admitted that after the article had been sold, or passed into the hands of the retail dealer, and became incorporated with the general mass of property, it was subject in all respects to state regulation. It seemed to be conceded in the arguments in that case, that a power in the state to control the use of the article after it had passed out of the hands of the importer, would greatly and essentially affect the right of the importer to import, for who would purchase of the importer, if he could not afterwards use and dispose of the article? But this was a consequence that could not be avoided, without going too far in the denial of the right of the states to regulate, in their discretion, the internal commerce of the state. It was admitted by the court in the case of *Gibbons vs. Ogden*, (9 Wheaton 203,) that state inspection laws, health laws, and laws for regulating the internal commerce of the state, &c., were not within the power granted to congress. We may add that the power regulating auction sales, and hawkers and pedlers, and markets, are all within the discretionary power of the state legislature, as much as the power concerning the sale of lottery tickets, or the preservation of the health and morals of the citizens, by interfering with the sale of obnoxious articles. These and a thousand other cases that might be put, all fall within the general superintending discretion of the state governments, as part of their own constitutional control over their own internal trade and dealings, and customs.

I consider this to be the doctrine of the cases of *Gibbons vs. Ogden* and of *Brown vs. The State of Maryland*, both of which were decided under the liberal and sound judgment of Chief Justice Marshall; and I am persuaded that the act of Massachusetts of April last would have been regarded by the supreme court, when they decided the case of Brown, as entirely free from constitutional objection, for that statute does not touch the importer, except very indirectly. It only goes to restrain the retail of spirituous liquors under the quantity of fifteen gallons at a time, and it evidently assumes that the article has passed from the importer into the internal commerce of the country. The importer may sell in that quantity and upwards at home, or for exportation to other states.

And if the case was doubtful under the decision in the case of *Brown*, yet there is a more lax construction on state authority in the late case of *New York vs. Miln.* (11 Peters, 1839.) There the court repeat all the exceptions in favor of state control over imported articles, mentioned in the former cases, and show a decided leaning in their favor. They go so far as to say that a state law which concerns the welfare of the people within a state, and relates to their duties as men and citizens, and to persons and things within its jurisdiction, is a regulation concerning the internal police of a state. No doubt the sumptuary law in question, prohibiting the sale of spirituous liquors, falls within the rightful cognizance of the state governments according to the doctrines of the supreme court of the United States, and I am very decidedly of the opinion that it would be fruitless to appeal to the supreme court of the United States against a decision of the supreme judicial court of Massachusetts in favor of the validity of the state law.

2. As I am of opinion that the act of April 1838 is not against the constitution or laws of the United States, the second question becomes unnecessary. Yet as the gentlemen who have done me the honor to consult me, may still be disposed to try the experiment, I should in that case advise, that whenever a suit is brought for a penalty for selling contrary to the act, that the defendant demur to the bill or declaration, or set up by way of defence that the act is repugnant to the constitution of the United States, and if overruled, as he would be, that he appeal to the supreme judicial court of the state, and if the judgment against him be affirmed, as it would be, that he then, under the direction of the counsel who has conducted this defence, appeal by writ of error to the supreme court of the United States, and a decision there will put an end to all litigation on the subject.

JAMES KENT."

New York, May 12, 1838.

If this opinion is tenable, we may lay a tax on foreign goods coming coastwise or in any way indirect to our state, except they be in original packages and on the importer's account; and we may do the same in regard to our American manufactures, which now pay tribute to indirect routes, all of which rights we may and should exercise in virtue of our sovereignty over our territory and population.

Your committee see no objection to the immediate legal adoption of this alternative; but they deem that it will be inexpedient to recommend the adoption of that which the public mind is not prepared to sanction, until this subject shall have received their further consideration. They beg leave, however, to recommend an amendment to the law in relation to merchants' licenses, which is no other than a legal exercise of internal police which exists in every state of the Union; some having adopted its use for the purpose of protection of various persons or branches of trade, and others for revenue. In the state of Virginia and North Carolina it has been adopted both as a system of revenue and a means of internal police, and may with advantage be altered and amended to the great improvement of both objects. In the year 1837 we had fifty-seven wholesale merchants, as follows:—Norfolk 19, Richmond 17, Petersburg 16, and Wheeling 5, each for the consideration of $60 per annum. In the same year we had eighteen auctioneers, to wit: Richmond 6, Norfolk 4, Fredericksburg 3, Lynchburg 2, Wheeling 2, and Portsmouth 1, at the sum of $90 per annum. In the same year there was granted to the 115 counties and 8 cities, boroughs, &c. 3836 retail licenses at $20 per annum, all united producing a revenue of near $73,000.

Your committee estimate that the retail dealers purchased goods, wares and merchandise in the said year, to the amount of $38,736,000 and estimate the rates of their purchases as follows:

No. of merchants.		*Am't. of purchase.*		*Total am't.*
25	who buy say	100,000	is	2,500,000
50	do	75,000	do	3,750,000
75	do	50,000	do	3,750,000
100	do	40,000	do	4,000,000
125	do	30,000	do	3,750,000
150	do	25,000	do	3,750,000
175	do	20,000	do	3,500,000
200	do	15,000	do	3,000,000
250	do	10,000	do	2,500,000
300	do	8,000	do	2,400,000
350	do	6,000	do	2,100,000
400	do	4,000	do	1,600,000
500	do	2,000	do	1,000,000
1136	do	1,000	do	1,136,000
3836				$38,736,000

Of this amount it is believed that not more than $4,500,000 value of merchandise both foreign and domestic, were introduced into the state after the manner of a direct trade; and therefore a tribute was paid to the indirect trade on the amount of $34,236,000, which amount of supplies, if received direct, would not cost the merchants of our ports more than $25,000,000. But this is not all the indirect business, inasmuch as a very large amount of articles purchased of the consumers are purchased in other states by retail to the neglect and injury of the retail dealers who have paid the state for the privilege of furnishing the citizens with goods by retail.

Your committee beg leave to suggest the inquiry whether citizens who thus act the part of merchants to the injury of our own markets, and the prosperity of the state, should not in justice to the retail dealer, and to the revenue, pay some equivalent in the form of a license. It is manifest that the license law of this state was enacted with the design that the retail dealers should purchase their supplies from the wholesale dealers and auctioneers within the state; and were they to do so, the revenue would be greatly improved, as not less than five hundred wholesale dealers would be sustained at this time who now pay revenue to other states. If by discriminating licenses our trade were thus restored, the business of the state would command abundant supplies; and a direct export and import business and trade with the country would establish a sound condition of domestic exchanges, and save us from panic and alarm, when convulsions ensue consequent upon the over-trading of other states. And manufacturers, mechanics and artizans would find a prosperous home among us. It is notorious however, that our retailers purchase nearly their entire supplies in other states, and from dealers who contribute nothing to the support of our government, nor does the profit of the business add to our wealth or to the value of our town property; but, on the contrary, we are impoverished, inasmuch as the profits drawn from our labor and added to the capital of our rivals increase their strength in the ratio with which we become weakened and exhausted.

It is obvious that the little trade which we now enjoy is from our smaller retail dealers, and from them we derive benefit and they pay as large a sum for a license as the largest class of retail dealers: for example, those who purchase from one to two thousand dollars per annum, pay from one to two per cent. on the amount of their business for a license, and our larger dealers who purchase exclusively in other states pay only about one-fifteenth part of one per cent. for theirs.—Your committee, therefore, deem it due to justice and patriotism to reduce the license of the smaller class of retails, and especially those who purchase their entire supplies in the state, and recommend the enlargement of the same paid by dealers who purchase any portion of their supplies in other states, to a sum not less than two hundred dollars, and the adoption of a new classification of dealers is recommended, to be denominated the *Domestic* Dealers, being such as purchase exclusively within the state, and *Foreign* Dealers, those who introduce and sell goods from other states; and in this latter class we would embrace all commission merchants, factors and consignees who are the accesaries of the indirect introduction and sale of merchandise. Your committee are deeply impressed with the opinion, that this small amendment of our system of internal police, will immediately restore to our ports an export and import business, foreign and coastwise, to the amount of $30,000,000, annually; and if our merchants are found incompetent to supply the demand, those merchants who now enjoy the business of our retailers, will come from other states and compete for the rich boon which so simple a legislative remedy will wrest from them. Make our business worth competing for at home, and competition will soon, very soon, be equal to the demand. Your committee are incompetent to estimate all the advantages which would speedily result to our seaports and the towns of Winchester, Wheeling, Charlestown, &c. as they would command the trade of the retail dealers of each respective vicinity; and it will soon be manifest that under all the evils to which they might feel subjected from an enlarged license, that their larger operations would more than compensate, and the several small dealers in their aggregate would be saved the labor and expense of about eight thousand journeys annually to northern cities to obtain that which can be obtained on better terms at home. It is an axiom to be relied on in all operations that a subdivision of labor facilitates perfection. Your committee will therefore add that our retail business may be done with far less capital, as the merchants who are near the markets from which they obtain supplies may purchase more frequently and not be subject to purchase at any time too large amounts, and less loss will be sustained to them by change of fashion or damage, or from the pecuniary pressure consequent upon the use of credit beyond the means of payment. This simple system (humble as it is) once put in operation, will enable the people to unite their best exertions with the great cause of internal improvement, which will soon render the remote portions of Virginia and North Carolina as familiar in intercourse as they are friendly in sentiments.

Your committee will further remark that a prosperous business will enable us to accumulate capital from our labor and enterprise; and they flatter themselves that future legislation will extend such fostering privileges as our best interests and *investments* may require.

Your committee, prompted by sentiments of filial patriotism and devotion to our *whole country*, will further add, that the restoration of our trade and prosperity, through the exercise of our clearly reserved rights, giving our citizens and all who become such, great benefits, without infringing on their equal privileges, or the rights of the citizens of other states, will be another patriotic example of the Old Dominion, which will be followed by our suffering sisters; and our equal prosperity and success will abate all sectional jealousy or envy, and preserve our UNION *for ever.*

Your committee beg leave to close their labors with the following resolution:

Resolved, That this convention appoint a committee consisting of twenty-one, whose duty it shall be to memorialize the legislatures of Virginia and North Carolina on the subject of their internal mercantile police and such other matters as are direcctly connected with the restoration of that trade which is enjoyed by citizens of other states.

LEGISLATIVE AID TO AGRICULTURE.

No. II.

Agricultural Societies.

Agricultural Societies have as yet been the only establishments in Virginia designed as means to improve agriculture; and these have been planned, and carried into operation, (when any operation followed,) entirely by individual effort, and at the expense of the members of the several societies. Without exception, they have been so defective in their organization, and plan for working and for producing the ends designed, that but few have lived long enough to work at all; and those few which have possessed more vitality, have had almost no other element of value. Of the greater proportion of the many agricultural societies which have already existed in Virginia, the meeting and hearing the first address from the first president of the society, constituted the only public or known act, before the speedily sinking into death, or lethargy and oblivion. Some few individual members of some few of these societies have indeed presented very interesting and useful communications on agricultural subjects; but this merely proves, what no one would doubt, that agriculturists distinguished for intelligence and public spirit, are not divested of these qualities, and do not always cease to exercise them for the public good, in consequence of their becoming members of agricultural societies. But it is denied that the eliciting these communications has been caused by the fitness of any such society for that purpose. All these societies, though in different degrees, have been deplorably unfit to stimulate inquiry and effort, elicit information, or, in general, to promote the improvement of agricultural knowledge, in science or practice.

Lest this general opinion should be deemed too censorious, or as having special reference to societies still existing, and to their recent action, or inaction, (all of which is disclaimed,) we will here quote at some length, as expressive of our views of the general defects of agricultural societies, and the suitable remedies, the words of an article which appeared nearly six years ago, in one of the early numbers of this journal.

"A remarkable and notorious characteristic of Virginians is to commence the support of any good and popular scheme, with vehement and overflowing zeal; and having thus wasted their energy in the outset, to become weary, relax their exertions, and finally cease entirely to make them, by the time they are most wanting. Yet, perhaps, the deliberate judgment of each individual is as much in favor of the object, when he thus abandons its support, as when he first undertook, and gave all his strength, to commence the operation. We act more from feeling, than from reasoning. We start forward to aid a good cause, as most of us would rush to a joyous festival; and when the excitement of pleasure is over, we as readily yield to the reaction of feeling—the wearisomeness and lassitude which always follow the pursuit and enjoyment of mere pleasure.

"But besides this our national failing, which unfortunately affects all our public institutions, there are other evils which press particularly on agricultural societies, and are sufficient to destroy first their usefulness, and next their very existence.

"When the formation of an agricultural society is first proposed, there are plenty of members to be obtained. Each is willing to give his name to support the scheme; and he is willing also to add a little of his time, and a small contribution in money. But very few think of becoming *working members*, or of doing any thing as individual cultivators of the soil, to aid the object of the association. They meet at the stated times for one or two years—find that they have no communications to hear—each member thinks or declares that the society is useless, and wonders that it should be so—and finally, (and necessarily,) it sinks into contempt and dies, without even the little respect of a vote being taken for its dissolution. Of all these perfectly useless members, there may be scarcely one who might not have rendered some service, by making experiments or observations, and reporting the results: yet each one is kept silent and useless by false shame, and the fear (if he should make the attempt) of not being *distinguished* as an agricultural writer.

"So much for the mass of private members. Next let us look to the officers, on whom much more depends, to secure the usefulness and permanency of the society.

"When the society is first formed, one of the most aged, respectable, intelligent and popular members will of course be made the presiding and first executive officer, on whose zeal and energy, the success of the scheme must mainly depend. Such a man will generally be justly entitled to the love and esteem of his fellow-members—perhaps he will stand equally high as a farmer, or as a man of general and valuable acquirements. But if he wants zeal and energy, (as must be expected of most old men,) the highest other qualities will not make up for these deficiencies. After such an appointment, the high respectability and popularity of the individual forbids a change; and if he should prove an inefficient president, the society is soon *overlaid* and destroyed by his worth and dignity. The same observations apply, but with less force, to all the other subordinate officers of a society.

"To avoid these causes of danger to new societies, I will respectfully propose to those who may be their founders, a few innovations which I think will be found of use.

"I. Let the society be composed altogether of *working members;* and to be sure of that object, let no member be admitted, except he previously presents some report in writing, (however concise, or no matter how trivial the subject) of experiment made, or facts observed. Scientific and professional men, in their departments, could perform similar duties. Such a form of initiation would compel every member to "break the ice;"

and, generally, nothing more is wanting, to prove to them that they can do good service in this way to agriculture, and with credit to themselves. Let these reports, which would be presented as claims for admission, be always plain, simple and short; and in manner and form not beyond the imitation of any plain practical farmer. It would also be proper to require afterwards of each member, a small but certain amount of *working* service every year—as for example, the making and reporting of one or more experiments on some doubtful point in farming, or in any art or science connected with agricultural improvement. I do not mean to discourage the more general, speculative, and argumentative essays which have heretofore formed nearly all the communications to agricultural societies: but these might be safely left to be performed as voluntary duties.

"It may be objected that but few members would be obtained if such preliminary and regular duties were required. I think otherwise. Very few would object to write in the manner proposed, if it was made a duty, instead of being altogether voluntary, and if the performance was required of all without exception. But even if only ten members should unite on these terms, they would be more useful, and do more credit to themselves, than they could with one hundred more upon the ordinary plan.

"II. Let the duties of officers be so fixed and defined, as that the performance should be as little as possible affected by their individual characters and habits; and, by a fixed rule, require rotation in office, so that no officer shall serve two years in succession. Almost any member, who has zeal and activity, may fill well any office in a society—and a year's service would be sufficient to show in any a deficiency in those indispensable qualifications.

"If societies on something like this general plan were spread through Virginia, incalculable benefit to agriculture would be derived from thus instituting, accurately observing, reporting, and publishing hundreds of experiments, and ascertaining numerous important facts, which can be made known in no other way. If only twenty individuals, composing a society, would make so small a sacrifice as the duties would require, in as many as twenty different counties, and means were adopted to interchange communications, the result would be that each member would have the benefit of the labor of four hundred experimenters and recorders of agricultural facts, or scientific observations. Is not this an object worth seeking, and worth *working* to obtain? But if the plan was properly estimated, there might be ten thousand persons so operating, and they, and all the farmers of the commonwealth, enjoying all the benefit to be derived from combining all these many exertions of labor and intellect."

It may, at first, be deemed inconsistent with the previous expressions of general condemnation, that we should yet recommend agricultural societies as among the most effective means to improve agriculture. But it would be only upon a regular, uniform, and altogether different organization. The devising a proper plan of organization and of operation, should be one of the earliest and most useful labors of a board of agriculture; and the conforming to that plan should be the condition required for directing to each society a proportion of the state's bounty for this purpose.

Whatever might be the details of the plan, the operation and effect should be to induce *some action*, however small, by every member of every society, in learning and establishing agricultural facts by practical and careful experimenting, and in accurately reporting the results. There would be enough subjects of labor for all—from the philosophical chemist, operating solely in his laboratory, to the plain and even unlettered but judicious and sensible cultivator of the soil. The contributions to knowledge, which, in this manner, would be brought by the members of a single county society, would be very valuable to themselves and to the public, however small and apparently trifling each individual contribution might be. And when all the separate gatherings of fifty or a hundred county societies were brought together, by a state society, or the board of agriculture, and digested and put in form for general use, the amount of knowledge and of profit thus gained, in the course of a few years, would be beyond calculation.

The great advantage of thus operating through county agricultural societies, would be found in enlisting the aid of the labor and money of individuals to a very far greater amount than the treasury would, or could, alone pay for; even if paying money were sufficient to purchase talent and zeal. If the state were to offer $100, or even but $50 a year, to every county society which should contribute at least as much money, and in other respects would conform to the prescribed general plan of organization and procedure, it is likely that even that small encouragement would induce the formation of many societies, which would ultimately contribute ten times as much in money as they received from the treasury, besides their far more valuable exertions of labor and talent. To give more prominence, dignity, and effect, to the societies, they should by delegates meet annually in a general state society; and perhaps it might also be advisable to give that society more or less agency in filling the Board of Agriculture.

Agricultural Surveys

Would be excellent adjunct and co-operative means with properly organized agricultural societies, to aid the improvement of agriculture; or, they would well serve as substitutes for the societies before the latter are established, and encouragers and stimulants to them afterwards. Though proceeding by different modes, the proper end and objects of both surveys and societies are the same, viz: to gather together all the facts as to the existing state of agriculture, so as to inform the whole agricultural community of each useful particular practice, which is now known only in a small neighborhood, and to a few farmers. If this alone were effected, this general diffusion of the knowledge of the now existing but generally unknown improvements, and good particular practices in various parts of Virginia, would add at once many thousands of dollars of value to agricultural wealth in general throughout the state; which new value, would probably add immediately as much to the annual pecuniary profits of agriculture as would pay the annual expense of an agricultural survey, for as long as it should continue, and for as much cost of other aids to agriculture continued afterwards.

The great work of improvement effected by the

British Board of Agriculture was more especially produced by their very minute surveys and voluminous reports of the actual condition of agriculture in each county of the kingdom. Never was a great national expenditure more judiciously and profitably made; and unquestionable benefits were almost immediately obtained. The surveys had scarcely been in operation when they brought first to public knowledge two most important modes of improvement, which, though known and practised for many years in particular sections of England, had never been known, or even heard of, elsewhere. One of these was the plan of "warping," or raising and making great and valuable additions to the soil of alluvial lands, by arresting the muddy contents of tide-waters; and the other was Elkington's plan of vertical draining, which, when thus made known, obtained for the discoverer the distinguished and rare honor and reward, of a parliamentary grant of £1000. But though these cases are more manifest, and therefore more striking, it is likely that there were hundreds of others, of more general application and value, of which the knowledge was diffused by these surveys, to the hundred-fold greater profit of agriculture.

Though surveys, being executed by but few persons, would in some respects be of much less value than *working* agricultural societies, which would combine the labors of many individuals, yet the former would have a decided advantage in one important respect. Agricultural societies, however zealous and industrious, would not report much else than the good or commendable practices, or such as were so deemed. But surveyors would be required to exhibit the actual state of agriculture—the defects and the evils, as well as the subjects for approval and imitation. This would be an important part of their duty; and to know fully the existing evils caused to agriculture by ignorance and bad management, would be one of the most important preliminary steps towards reform, both general and particular.

The intimate acquaintance which the members of an agricultural society would have with the soil and agriculture of their own county or district, would be a very important advantage to their investigations, which would be wanting to a surveyor of districts to which he was almost a stranger. But on the other hand, the stranger, if a judicious observer, will be apt to be struck with many subjects of interest and value to all persons similarly unacquainted with the locality and its practices; and which residents there would not appreciate, whether for good or for evil, because they could not compare them fairly, and without prejudice, with other practices elsewhere.

In the present very imperfect state of our agriculture, it would not be requisite to have surveys made as minutely, nor reports as voluminous, nor to be at an expense, for the whole, at all approaching to those of the English Board of Agriculture. A very cursory and general, though correct view and exhibition of Virginian agriculture in its present state would suffice for this part of a general system of action; and at a future time, when great improvements had been produced, there would be more inducement for having surveys conducted more carefully, and reported more in detail.

The state of Massachusetts has the honor of having led the way and offered the example to her more agricultural sister states, of ordering and supporting an agricultural survey. The agricultural commissioner of that state, the Rev. Henry Colman, is now actively engaged in that duty; and we doubt not but that the profit hereafter derived by the commonwealth will fully accord with the public spirit and liberality which induced the measure, and the distinguished ability of the individual selected for the labor. Yet Massachusetts is scarcely an agricultural country, so unkind are her soil and climate, and so much are her industrious citizens devoted to other pursuits. The interest of Virginia in agriculture, and the profit which might be derived from a like measure of improvement, are twenty fold greater than those of her noble sister Massachusetts.

In several of the next points for consideration we will merely copy views which have long ago been offered to the readers of this journal in another form, with merely such present additional remarks, as may be necessary for explanation or extension. The following passages are copied from the "Sketch of the progress of agriculture in Virginia, and the causes of its decline and present depression," published in Vol. III. of Farmers' Register.

Agricultural Professorships.

"If agricultural professorships were established in our principal institutions of learning, young landholders who are there acquiring liberal educations might easily obtain a competent knowledge of the general principles of agriculture, without sacrificing the other useful parts of scientific instruction. If this object would not be a sufficient inducement to remain one more year at college, it would be an advantageous exchange in such cases, if the study of theoretical agriculture, and its connexion with chemistry and some of the branches of natural history, took up the time usually devoted to metaphysics and the higher branches of mathematics—the study of which will be of use to but few men, except as a good mental exercise—a kind of *gymnastics* for the mind. It will be easy to ridicule the agricultural instruction that could be acquired from the lectures of a professor—a mere man of books and of theory. But though it is freely admitted that no such course of instruction, *alone*, could make a farmer, yet it would be the best preparation for the future acquisition of practical knowledge. It would be folly to look to the lectures of a professor for instruction in practical operations: but we might expect them to furnish the general and true principles of agriculture and its kindred sciences, (so far as they are connected,) without some knowledge of which no man can avoid committing continual blunders, and meeting with continual losses, as a practical tiller of the earth. For example: a farmer cannot know whether he is proceeding right or wrong in the very important operations of preparing, preserving, and applying manures, without some knowledge of the chemical ingredients of the materials used, of the changes produced by fermentation, and of the functions of the plants which are designed to be fed, and of the composition and properties of the soil intended to be enriched. Even a *little* knowledge on these points would serve to guard against serious waste and loss on every farm—the total amount of which makes a hundred fold greater national and annual loss, than all the expense of agricultural professorships, and of every other means for instruction that I shall advocate."

Though fully maintaining the foregoing views as to the general advantages of an agricultural professorship, still it is proper to state an important objection to such an institution being among the *earliest* measures of aid to be adopted by the state. In the present very defective state of agriculture in Virginia, there is probably not a single individual who is qualified to fill such a professorship with credit and usefulness. Very little of scientific agriculture is known—and the best practical farmers, even if they were well qualified by their scientific attainments, are too fully and profitably engaged on their own farms to accept such a post. It could not possibly be well filled at present; and therefore this benefit to agriculture, great and valuable as it would be under different circumstances, should not be attempted until other, and more available and sure means, had been permitted to operate.

Experimental Farms, or practical Schools, for experimental agriculture.

"Experimental farms, under proper direction, would also serve a most valuable purpose for increasing general agricultural information. But it would be a mistake, fatal to the object in view, if such establishments were expected to present a system of pattern husbandry, or even to yield any clear pecuniary profit whatever. Such expectations would necessarily be disappointed—and thus would cast discredit on the whole plan. Experiments, if judiciously conducted, and accurately reported, would be more effectual than any other means for conveying valuable information to the agricultural community. They *cannot* be made extensively by private individuals—for the plain reason that they require too much expense of time, labor, and, money, and, in general, are attended with loss, even when the results are most valuable for the information they give. A farmer might lose $100 by making a series of experiments, of which the results might yet be worth $100,000 to the community at large. Hence, it is in vain to hope for such proceedings, unless induced and supported by the funds of the community; and it is foolish to count on deriving direct and immediate profit from experiments, whether conducted by public bodies or private individuals. Yet this foolish expectation is very general—or at least it is commonly deemed sufficient ground to condemn and ridicule any experiments as worthless, if their immediate result is loss to the inquiring and public-spirited individual who instituted them. Yet who ever counted on deriving direct pecuniary profit from any course of experiments in chemistry or natural philosophy? And without many such costly and losing experiments, the world would not have obtained the benefits of the steam engine, of the machinery for spinning and weaving cotton, the modern processes of bleaching and coloring, and hundreds of other improvements in the arts. If judged by the test of profit, as usually applied to agricultural experiments, Watt and Fulton, and Arkwright, would have been pronounced mere fanciful schemers, if not fools, not only because of the expense of their experiments, but perhaps because neither of them could bring into operation the mechanical skill, and habits of business, necessary to the highest perfection and greatest profit of their splendid discoveries."

In the introduction to these numbers, there was presented, as a general illustration of legislative action and aid to agriculture, the manner in which new practices could be profitably tried and taught. The operation there described, as to silk culture, would belong to the department now under consideration; and it would be but one, (though now a very important one,) of the hundreds of doubtful or untried subjects which might be fully and correctly tested, and the value and worthlessness clearly established on an experimental farm, so as to instruct thousands of the result, who, without such instruction, would incur all the loss, either of neglecting to avail of a profitable practice, or of pursuing an unprofitable one.

An experimental farm would be an excellent precursor of an agricultural professorship, and would co-operate admirably with the professorship, after one is *properly* established. Such a farm then, in addition to its other more important uses, would be a great out-of-doors laboratory and apparatus for illustrating the scientific lectures of the professor of agriculture.

Though it never should be considered that an institution for agricultural experiments is to be a model or pattern farm for general husbandry, or for any regular system of operations, (which indeed would be subversive of its proper design and greatest value,) and though loss, instead of profit, on the whole, must be caused by any such course of experimenting—still some particular and important experiments or new practices may be found profitable from the outset, and by their profits, may help to sustain the cost of others. Thus, if the state, on an experimental farm, had led and pointed out the way to the great improvements which have recently been made in lower Virginia, by the use of marl, it may be presumed, that all the usual wastefulness of public works would not have prevented that business proving highly profitable to the institution, in a pecuniary point, though in an inferior degree to the profits of private adventurers. A state institution, if existing, might have introduced this great improvement fifty years earlier than it has been done by individual exertion and risk; and if such had been the case, the commonwealth would now be twice as rich and as populous as it is. But without counting on new experiments being profitable to the institution, and even if such directly profitable exceptions to the general rule were to be altogether wanting, still the indirect and resulting profits to the commonwealth would be sufficient to make the most ample return for all the cost and loss incurred.

"It has often been recommended, and by high authorities, that *pattern farms* should also be established, to teach agriculture by example. This we should strongly oppose—and for the reason that, from necessity, what might be *named* a pattern farm, would *prove* to be any thing but an exhibition of good and profitable husbandry. Instead of attempting such an establishment, it would be better to make use of, as an additional course of *practical* instruction, the now existing farms of many private individuals, which are truly patterns of good and profitable management. Many such farms might be named, deserving the character, in various parts of Virginia. It is evident that no one of them, even if managed in the most perfect manner, according to its location, and the peculiar circumstances of its proprietor, could serve as a general pattern farm. But one, for example, might exhibit a pattern for clover fallow and wheat culture, on the singular and valuable "red land" of the Southwest Mountain slopes—another for the same, on the rich, flat loams of James River—another would show the profitable combination of tillage and grazing west of the Blue Ridge—another, the best mode of tilling and enriching the more sandy lands of lower Virginia—and all might accord in some common points of resemblance, in addition to the merit of excellent general management. The proprietors of such farms might very properly be considered as *adjunct and practical professors of agriculture*; and would render important services as such, by each receiving in turn, as pupils, two or three of the young men who had previously passed through the course of theoretical instruction. On these farms, and under such instructions, a young man could learn more of practical and profitable agriculture in a few months, than from his own solitary and unassisted efforts on his own farm, continued throughout a long life."

From the Gardener's Magazine.

ORANGE GROVES OF FLORIDA.

By Alexander Gordon.

The following remarks are the result of observations made during an extensive and varied tour, (just terminated,) over an extent of several thousand miles, in prosecuting which I have seen much which I consider both instructive and interesting. For the present I purpose confining myself to a few brief observations on the state of the orange groves, &c., at the city of St. Augustine, E. F.

You, of course, are aware, St. Augustine is one of the oldest, if not the very oldest city within the jurisdiction of the United States, and has long been a place of great resort for invalids afflicted by the pulmonary and bronchial complaints. I had visited this city in 1831, and I confess I was in perfect raptures with its diversified beauties, but particularly with its *orange groves*. It then appeared like a rustic village, the white houses peering from among groves of this delightful fruit which grew in the greatest luxuriance. The clustered boughs covered with their golden produce, yielding a rich harvest to the owners, and affording a delightful shade to the foreign invalid, when he cooled his fevered limbs and imbibed health from the perfumed atmosphere. While the ear was gratified and the feelings soothed by the various notes of that delightful songstress the mocking bird which found a ready shelter amid their verdant foliage. But, alas! on my visit the past spring, in vain did I look for those rural bowers, so gratifying to the eye and invigorating to the system. Not a single tree of any magnitude to indicate its former grandeur. The imagination could scarcely conceive such a perfect metamorphosis. For a long period of years, the orange had had flourished without interruption from frosts or other casualties. The city of St. Augustine was peculiarly favorable for this semi-tropical fruit. The soil is naturally sandy, but rich in calcareous and vegetable deposits, consequently well adapted to the growth of the orange and other horticultural pursuits. When I was there in 1831 the orange had become the staple commodity of the city's commerce, and subsequently to that time I understood several millions had annually been exported. Numerous groves of young trees were planted, and $10,000 had been refused for a grove consisting of only 2 or 3 acres. Extensive nurseries could scarcely supply the demand for young trees. A vast and lucrative field opened to the enterprising horticulturist. On the native orange were engrafted the choicest varieties of other climates with the most perfect success. Prospects of immense wealth seemed beyond a doubt, but

"There came a frost—a withering frost."

During the month of February, 1835, East Florida was visited by a severe frost, much more severe than any before experienced. A cutting N. W. wind which blew ten days in succession, but more violent for about three days. During this period the mercury sank 7 degrees below zero. The St. John's river was frozen several rods from the shore, and afforded the astonished inhabitants a spectacle as new as it was distressing. The orange, the fig, and all kinds of fruit trees were killed to the ground; many of them were completely annihilated; but a considerable number have started again from the roots. The wild groves in Florida suffered equally with those cultivated, at all events as far south as Lake George, and the inhabitants were thus deprived at one fell swoop of their only resource. But on my visit, in the month of April last, I was happy to find the inhabitants were not totally discouraged, for there are many thousands of young trees now ready for planting out, and in a few more years, it is to be hoped, St. Augustine will again exhibit its wonted appearance. The oranges grown here were considered decidedly superior to those imported from the West Indies, and as so long a period has elapsed since they experienced so calamitous a visitation, (I believe not since 1775—6,) it certainly is worth while to persevere.

CLIMATE OF LOUISIANA.

The Natchez Free Trader is publishing a lecture delivered by Dr. S. A. Cartwright before the Mississippi Lyceum. This lecture is much in favor of the climate of Louisiana. Speaking of the parishes south of the 30th degree of north latitude, it says:

"In 1830, they contained 38 persons over 100 years of age, whereas the whole of the New England States, with a population of 1,954,704, including upwards of 20,000 negroes, only contained 35 persons over 100 years of age. France, with 36,000,000 inhabitants, only contained 537 persons over 100 years of age. If France were as favorable to longevity as the land of the Jussieua Grandiflora, it ought to contain upwards of 16,000 individuals over 100 years of age.

"The persons who die in the northern states, in the prime of life, by consumption, typhus and inflammatory complaints, are about equal, or even exceed the number which die in the south of malarious diseases. But the region of the country in which the Jussieua Grandiflora flourishes, is, from its mild climate, comparatively exempt from consumption, typhus and inflammatory affections; and by reason of the anti-malarious properties of the plant, it is singularly exempted from all that tribe of diseases which are produced by marsh miasmata, or by the unwholesome air of swamps called malaria. The plant, it would seem, converts into its own nutriment those very impurities of stagnant water which in other situations load the atmosphere, at certain seasons of the year, with noxious effluvia."

[The rare quality attributed above to the Jussieua Grandiflora is sufficiently valuable and important, as well as strange, to deserve being more fully stated and explained. We confess our entire ignorance on the subject, and will be glad to receive, from any better informed source, a full account of this remarkable plant, the effects which it is supposed, or known, to produce, and to what distance, northward, its growth and operation may be extended.—Ed. Far. Reg.]

From the Southern Agriculturist.

SECRET FOR MAKING NEW [AND EXCELLENT] WINE.

[An esteemed friend handed us the subjoined documentary evidence, in support of the pretensions of Mr. Da Costa, to the possession of a secret for making "new wine in *six* days," and for converting "most inferior" into the "most excellent wines in the space of *two weeks*." The gentlemen subscribing the certificate furnished Mr. Da Costa, have not said they all saw the process of making new wine in six days, and improving most inferior wines in two weeks, but as their respectability forbids the slightest suspicion of their countenancing a trick of this or any other kind, we must presume they did all see the wonder performed. Another reason for believeing *they all saw* the grape converted into excellent wine in *one week*, and undrinkable, into good wines in *two weeks*, is to be found in the fact that two of their number have agreed to pay FIFTY DOLLARS each, "so soon as he (Mr. Da Costa) shall deliver Mr. James S. Guignard full and ample directions in writing, showing clearly the proper mode and manner of making, improving, and clarifying of wines, as it is practised by him in their presence," i. e. in the presence of James S. Guignard, and Dr. Percival. The N. B. by Mr. Da Costa, we will believe the ebullition of honorable pride—strong in its truth. He claims the "system as his own," and he has good reason to be proud of a discovery, which must rank, in point of value and usefulness, among the most important of our times.

We commend Mr. Da Costa to the partonage of all the Agricultural Societies in our state. Hitherto, fear of the rot has been a bar to cultivating the grape upon a large scale. Mr. Da Costa now offers a remedy for, or a preventive of, this disease, and we trust he will find among us such liberal patronage, as to induce him to remain here. He has "lost his country and every thing there"—cannot we make him forget that loss? Let us try.

At present, the merchant is the most deeply interested in this wonder working discovery, and for his especial benefit, we request the editors of our daily papers to republish Mr. Da Costa's letter, and the documents inclosed. Many dealers have wines they are almost ashamed to sell, but cannot afford to give them away, or afford even, the loss by sales at auction. Let such purchase the secret; it is worth FIFTY dollars, and, be it remembered, it will, unlike any other tax, be but once paid.

If Mr. Da Costa's system promises to prevent rotting of the grape, every vine growing country in the world is interrested in his discovery; and as he is with us, he should be aided and encouraged in his experiments—if experiments they are; if they are not, and his offers are based upon established facts, he should be kept among us at almost any cost. The late Mr. Herbemont, of Columbia, proved to the conviction of the most sceptical, that the grape can be cultivated to greater advantage than cotton of any name, or staple. The friends of our country generally, and of *economy* and *temperance* especially, should zealously encourage every effort to make the culture of the vine one of our ordinary pursuits.

Ed. South. Agr.]

Columbia S. C., 13th October, 1828.

My much esteemed Sir,—Permit me to take the liberty to address myself to you on this occasion, for the purpose of making you acquainted with my art of preparing wines and vines; because you and your friends may have want of me in your city. In such case, if you could assure to me a good portion of bad wine, wine of the most inferior quality, good for nothing; wine with bad taste and bad smell, almost vinegar; I can make it become *excellent wine* in the space of two weeks only. It is a fact; and the documents that I have the honour to inclose within, will prove to you my assertion. Please excuse me the liberty I take. Should you be so kind as to give me your answer, I will be ready to go to your city in the month of December next. Yours, truly and respectfully,

Correa Da Costa.

To J. R. Valk, Esq.

We, the undersigned, having seen and tasted the new wine made in *six days*, by Mr. Correa Da Costa, and also, the *very inferior wines* improved by him in *two weeks*—take pleasure to declare and certify, that the system of Mr. Da Costa is entirely commendable, as it is certainly the best American wine we have seen, both for quality and flavor, as well as expedition. In the space of *one week* from the gathering of the grapes, every vine planter may have excellent wine ready for sale; and the *most inferior wines* can be made into the *most excellent wines* in the space of *two weeks*, when prepared by the system of Mr. Correa Da Costa.

Mr. Correa Da Costa also informs us that his art extends to the planting, rearing, trimming, grafting, inoculating, and cultivating the vines—and he is of opinion that a vineyard attended to under his management, will be free from that destructive malady, the rot, which has so often blasted the fairest prospects.

Columbia S. C. Oct. 5th, 1838.

James S. Guignard,	Owen McKiernan,
Alexander Herbemont,	Col. McCord,
Dr. Percival,	I. D. Mordecai,
Dr. Wells,	Robt. Mayrant,
Dr. Marks,	John Nuffer,
Dr. Fitch,	Maj. Thos. Taylor,
G. W. Daniel,	A. S. Johnson,
Sidney Crane,	Major Starke,
W. B. Thomas,	Dr. John Wallace,
Kinsler, McGregor & Co.	Col. W. Hampton.
A. L. Kline,	Dr. J. G. Guignard,
P. W. Knapp,	Benjamin Tradewell,
Aug. W. Eaton,	Dr. E. W. Fisher,
Dr. Gibbes,	Dr. John Fisher,
James L. Clark,	E. Friday.
Col. Preston,	

Columbia, Oct, 8, 1838.

From the specimens exhibited by Mr. Correa Da Costa, of his improvements of bad and inferior wines, we deem that much benefit will result to the wine makers and vine growers of this state, by obtaining his art of so doing. We do, therefore, for the purpose of obtaining his *valuable secret*, promise to pay to him the sums opposite to our respective names, so soon as he shall deliver to Mr. James S. Guignard full and ample directions in writing, showing clearly the proper mode and manner of making, improving, and clarifying of wines, as it is practised by him in our presence. And should any of us wish to have our wines improved, we are not to pay to him more than twenty-five cents per gallon, exclusive of ingredients, and *which secret we are to keep to ourselves.*

James S. Guignard,	\$50
Dr. Percival,	\$50

N. B. A good impostor may deceive a half dozen fools in a large place, but the "*American wine*," after having been improved by my own hands, according to *my own system*, and in the presence of Major Guignard, cannot deceive *thirty-one* respectable gentlemen in Columbia. Every person that has compared the samples of the inferior wine with the same wine improved by me in *two weeks*, has expressed his amazement for such wonder. It is a fact, it is *not* a trick. My *improved* wine is *immortal*; keeps for ever, and every day becomes better. With regard to my *new wine* made in *six days*, I think it is a enough to be mentioned, to be declared a wonder. Both wines have been seen and tasted by a respectable community of this town, and I have the glory to offer my services to Columbia with *my system of preparing wines and vines*—a good source of speculation and profit. I have trusted my secret to Major Guignard, and as he has seen every thing that I have made, to him I refer those that say with the incredulous disciple," it is necessary to see for to believe it." The fact is that it is the true transubstantiation of the wine. The knowledge of this united system is absolutely necessary to all vine growers and wine merchants. Wine, worse than vinegar, that has been sold at 12 cents per gallon, is now *excellent wine;* vineyards which have produced *only rotten grapes*, will, in the future, produce excellent crops of aromatic juice for making *American wine*, in order to rival the best *improved wines* imported from Europe. The new wine made in *six days*, requires the expense of *four dollars only, in each* 120 *gallons of juice.*

Messrs. Abram Geiger, has about 60 acres of land planted with vines; Herbemont 40 acres; Guignard 12; Neuffer 10; and perhaps 10 acres more belonging to Dr. Percival, Dr. Marks, J. L. Clark, D. Ewart and L. Sherman: all these vineyards *cultivated as they ought to be* would yield a profit exceedingly superior to a plantation of cotton of the same extent.

Having unfortunately lost my country and every thing there, however, I can manage the sword and the plough alike. In the four years of my emigration, I have travelled throughout all Europe: I have visited the capitals of *all nations;* and I can declare better that any body else, that Guignard wine, Richland wine, Amaranth wine, and Costa Madeira, can be transported to Europe, and be presented at the best tables, because they are, if not superior, at least equal to the best wines made *and prepared* in Madeira, France and Spain.

All these wines are now ready for sale, at Mr. Sidney Crane's, at \$1 per bottle.

Persons wishing to have for themselves the secret of making new wine in *six days* (which, of course, is a great acquisition for the next vintage) and also the secret of improving bad wines in two weeks, are invited to call at Mr. Guignard's office at the Court house, where the list of subcribers is open for that purpose.

Correa Da Costa.

CURIOUS EXTRACTS FROM THE ANCIENT LAWS OF VIRGINIA.

(Continued from No. 9.)

The next enactment (of 1645) which will be presented was an important measure of reform, and a considerable approach made towards the better security of popular rights.

"Whereas the anncient and vsual taxing of all people of this collony by the pole, equally, hath been found inconvenient and is become insupportable for the poorer sorte to beare, This Assembly haveing taken it into considerations have for their reliefe hereafter thought fitt to alter the same: Be it therefore enacted, That all publique leavies and county leavies be raised by equall proportions out of the visible estates in the collony, The conformity of the proportions to be as followeth, (vizt.)

One hundred acres of land at	04 lb. tobacco.
One cow, 3 years old at -	04
Horses, mares and geldings at	32 a peece.
A breeding sheep att - -	04
A breeding goate at - -	02
A tithable person at - -	20"

—*Statutes at Large*, p. 305, vol. I.

At the same session, the lawful money of Virginia was changed from tobacco to coin. The first part of the act is as follows:

"The Governor, Council and Burgesses of this present Grand Assembly having maturely weighed and considered how advantageous a quoine current would be to this collony, and the great wants and miseries which do daily happen vnto it by the sole dependency vpon tob'o. have at length resolved and enacted, and be it by the authoritie aforesaid enacted as the onely way to procure the said quoine and prevent the further miseries, That all peeces of eight in Spanish money be valued and taken in payment, att the rate of sixe shillings and all other Spanish silver quoines proportionably which shall be brought into the collony: And whereas it is conceived that the said quoine will not continue with vs vnless we have a leger quoine, Therefore serious consideration had of the many wayes tending to that effect, It was at length generally allowed, That a quoine of copper would be the most beneficial to, and with most ease procured by the collony, And that after proclamation made by the Governour and Council that all person or persons within this collony whether merchants or others do desist or leave off tradeing for tob'o. vpon the penaltie and forfeiture of the thing so bought or sold, The one moyetie whereof shall be and come to the informer, and the other to the benefit of the state."—p. 308.

In 1647 the former law compelling the planting of two acres of corn per head, being found insufficient, was again strengthened by additional guards and penalties.

The next act prohibits the exportation of corn, and limits the price of all sold in the colony. Such restrictions would necessarily operate to discourage the production, more than could be counteracted by all the enactments to compel planting.

"Whereas the great scarcity of corne is like to produce much want and misery to divers of the inhabitants, vnles timely prevention be made by prohibiting of exportation of corne, and against hoarding and ingrossinge thereof, to the intent to exact vpon theire poore neighbours by extream and vnreasonable rates to the vtter vndoing of whole ffamilies: Bee it therefore enacted by this Grand Assembly that no person for this ensueing yeer shall exporte any manner of English or Indian graine or corne out of the lymitts of the collony, in which act all strangers as well as inhabitants are included; Add for preventing of all hoarding and ingrossing of corne, It is alone enacted, That noe person or persons whatsoever shall sell, bargaine, barter or exchange any Indian corne either directly or indirectly above the rate or valew of one hundred pounds of tobacco per barrall, vpon the penalty of five hundred pounds of tob'o. for every barrell of corne that shall be exported as aforesaid, The moyetie of which fine and forfeiture shall be and come to the King's Majestie and the other halfe to the informer."—p. 347.

The taking of fees by attorneys, and the profession itself, were not put down by the former act; and therefore the following was added:

"It is thought fitt that vnto the act forbidding mercenary attorneys,* It bee added that they shall not take any recompence either directly or indirectly. And that it be further enacted, That in case the courts shall perceive that in any case either plt. or defendant by his weakeness shall be like to loose his cause, that they themselves may either open the cause in such case of weakness or shall appoint some fitt man out of the people to plead the cause, and allow him satisfaction requisite, and not to allow any other attorneys in private causes betwixt man and man in the country."—p. 349.

In the same year, (1647,) was revived a former act, forbidding the legal recovery of any "wine or strong water debts."

At the session of 1656, efforts to encourage silk culture by law, which had been so early adopted as the policy of the government, were again made, by the following acts.

"Whereas by experience silke will be the most profitable commoditie for the country (if well managed) and as the greatest conducement therevnto required, is provision of Mullberry trees, *Be it enacted and confirmed by this present Grand Assembly* that everie proprietor of land within the collony of Virginia shall for everie one hundred acres of land holden in ffee, plant vpon the said land tenn mullberry trees, at twelve foote distance each from other, and secure them by weeding, and a sufficient ffence, from cattell, horses, &c. between this and the last of December, 1658, and for everie tree that shall be wanting, or vntended in manner aforesaid of the said proportion at the said last of December, 1658, he the said proprietor that shall be soe delinquent shall pay tenne pounds of tobacco," &c.—p. 420.

"That George the Armenian for his encouragement in the trade of silke and to stay in the country to follow the same have four thousand pounds of tobacco allowed him by the Assembly."—p. 425.

At the next session (1657—8) the following additional regulations were enacted, to encourage silk and other products.

"For the better encouragement of the inhabitants for the makeing of staple commodities in this collonie, *Bee it enacted by this present Grand Assembly* that what person or persons soever shall at any time hereafter make in this collonie so much silke, flax, hopps or any other staple comoditie (except tobacco) as is worth two hundred pounds sterling, or English wheate to the value of five hundred pounds sterling in one yeare and exporte the same or cause the same to be exported, or shall first make two tunne of wine raized out of a vineyard made in this collonie shall have given him by this countrey for an encouragement ten thousand pounds of Virginia tobacco.

Wheate valued at five shillings per bushell.
Silke at twenty shillings per pound.
fflax at six pence per pound.
Hopps at twenty shillings per hundred.

What other staple comodities shall be raised to be valued by the Assembly."—p. 469.

At the same session, the following act was passed.

"Whereas it is generally supposed, That the makeing of silk will much conduce to the good of this collony, *Bee it therefore enacted by the authoritie aforesaid* that what person soever shall first make one hundred pounds of wound silke in one yeare within this collony shall for his so doe-

* Act VII of Nov. 1645.

ing be paid ffive thousand pounds of tobacco out of the publique levie."—p. 487.

The exportation of hides, iron and wool, was forbidden under heavy penalties at this session. The exportation of mares and sheep had been forbidden some time previous. It is surprising how long a time was required, and through what a course of loss and injurious experiments, for our ancestors, and the rest of the world, to learn the truth of the simple maxim of political economy, that to encourage the production of commodities, it is best not to restrict their sale, or circumscribe their market.

Two more silk laws were passed at the session of 1658—9.

"Whereas the act for mulberrie trees seemes rather troublesome and burthensome then any waies advantageous to the country, *It is hereby enacted*, That the said act for planting mulberrie trees shall be repealed and made void."—p. 520.

"For incouragement to the makeing of silke, *It is enacted*, That whosoever shall make ffiftie pound of wound silke shall receive from the publique as a reward of his dilligence tenn thousand pounds of tobacco, *Provided* he prove it to be all of his owne makeing."—p. 521.

Additional penalties were imposed at this session to prevent the "ground-leaves" of tobacco being sold. The prohibition of the exportation of hides and old iron was repealed.

The preamble, or recital of reasons, for the "Act for suppressing Quakers," passed 1659—60, is curious, and characteristic of the age.

"Whereas there is an vnreasonable and turbulent sort of people, comonly called Quakers, who contrary to the law do dayly gather together vnto them vnlaw'll Assemblies and congregations of people teaching and publishing, lies, miracles, false visions, prophecies and doctrines, which have influence vpon the comunities of men both ecclesiasticall and civil endeavouring and attemping thereby to destroy religion, lawes, comunities and all bonds of civil societie, leaveing it arbitrarie to everie vaine and vitious person whether men shall be safe, lawes established, offenders punished, and Governours rule, hereby disturbing the publique peace and just interest, to prevent and restraine which mischief, *It is enacted*," &c.—p. 532.

The following brief entries are some of the "Extracts from the minutes of the proceedings of the Governor and Council of Virginia," at an earlier time of the colony.

"*Dec.* 16*th*, 1631.

Because Edw. Grymes lay with Alice West he gives security not to marry any woman till further order from the Governour and Council.

March 25*th*, 1630. Tho: Tindall to be pillory'd 2 hours for giving my L'd. Baltimore the lye & threatning to knock him down.

6*th* 8*br*. 1631. The first informer of any slanderous reports of Governour or Council were to have the fine; this day one was whipt and lost his fine for concealing such a slander."—p. 551—2.

"1 *Feb.* 1632. Two maids got with child at sea, ordered to be sent back again."—p. 552.

"Stephen Reekes put in pillory 2 hours with a paper on his head expressing his offence, fined £50 sterling and imprisoned during pleasure for saying that his majesty was at confession with the L'd. of Canterbury.

Robert Sweet to do penance in church according to laws of England, for getting a negroe woman with child and the woman whipt."—p. 552.

At the session of 1660, the first after the restoration of the royal authority, under Charles II, among a medley of numerous orders of the "Grand Assemblie" are the following:

"Ordered that by reason of the vnconcionable rates, smiths do exact on the inhabitants of this countrey for theire worke, that the countie courts have power to regulate their accompts."—p. 11.

"Ordered that the horse way over Powatan swamp to James-Cittie be at Mr. Hunts mill and that he be allowed out of the levie next yeare ffive thousand, ffive hundred pounds of tobacco for repairing and maintaining the same for eight yeares except the county of James-Cittie before the tenth of ffebruary will vndertake the same on the same tearmes."—p. 12.

The last enactment, humble as was its object, may perhaps be considered as the first step taken by the government of Virginia to promote what in these times has been improperly termed "internal improvements"—or, correctly speaking, that one important branch of the internal improvement of the country, which is found in the construction of roads, canals, and other facilities for transportation and trade. It is greatly to be desired that the government would learn, and act upon, the truth, that to increase the products of the earth by wise legislation is still more necessary and profitable than merely to facilitate their passage to market. On this head, our legislators of the present day might profit by the example of their less enlightened predecessors; as, for example, in the next following order for defraying the expense of the first attempt to produce a new and valuable commodity. In this and sundry other such efforts, our ancestors were right in the principle, but their measures for encouragement of production generally failed, because the mode was faulty.

"Ordered that Daniel Dawen for his experiment of salte have his charges defrayed in towne out of the publique levie and bee exempted out of the Accomacke levie also."—p. 12.

The "rights of man" were not as yet well understood, or guarded very scrupulously. The "ordinarie sort of people" were not treated with much respect in those old times.

"Ordered that the honourable the governour have power to presse tenne men of the ordinarie sort of people, allowing each man two thousand pounds of tobacco per annum for theire services and to employ them toward the building of a statehouse."—p. 13.

Session of 1660-1.

"Whereas the lowe prices of tobacco will hardly supply the urgeing and pressing necessities of the inhabitants of the country, and those necessities by the importation* and sale of superfluous commodities soe augmented that very few can with theire annuall labour defray their annuall charge by which meanes they are reduced to that extremity that not being owners of their owne commodity (spent before made) they are forced to part with it at what rigorous rate soever the exacting merchant will please to propose for prevention* whereof *Bee itt enacted* that noe strong drinke of what sort soever, nor silke stuffe in garments or in peeces (except for whoods and scarfes) nor silver or gold lace nor bonelace of silke or thread nor ribbands wrought with silver or gold in them shall be brought into this countrey to sell after the first of February next under penalty of confiscation of the said goods by the sellar to the governor to be exported and the value thereof by the buyer to that good common-wealth man that shall discover it."—p. 18.

"Bee it enacted that the order of the governor and councell imposeing five shillings on each barrell of privision exported be confirmed and continue in force until the end of July next and then to expire and after that the exportation to bee free."—p. 21.

"Since flax seede cannot be procured to sowe in the time limited in the act provideing for the makeing of six pound of yarne per poll, *Bee itt enacted* that the time of putting the said act in execution be prolonged untill the first of march 1662 and that afterwards it be strictly observed."—p. 26.

The last act of this session was to revive the act for planting mulberry trees, (copied above,) which had been repealed by the act of 1658-9.

At the session of 1661-2, another act was passed offering rewards for killing wolves, which, as the preamble recites, was necessary because "great complaint is made of the frequent and many injuryes done by wolves to the cattle and hogs of several inhabitants of this country." At that time, Henrico was the most western, or the frontier county of the colony.

As the assembly had thought it necessary to limit the fees and exactions of attorneys, millers and blacksmiths, it is not surprising that physicians also were put under regulation and restraint.

"Whereas the excessive and immoderate prices exacted by diverse avaritious and gripeing practitioners in phisick and chirurgery hath caused several hardhearted masters swayed by profitable rather then charitable respects, rather to expose a sick servant to a hazard of recovery, than put themselves to the certaine charge of a rigorous though unskilfull phisician, whose demands for the most part exceed the purchase of the patient, many other poore people also being forced to give themselves over to a lingring disease, rather then ruine themselves by endeavouring to procure an uncertaine remedy, for redrese thereof for the future, *Be it enacted* that it shalbe lawfull for any person or persons conceiving the accompt of the phisitian or chirurgion unreasonable to arrest the said phisician or chirurgion to the generall or county court where the said phisitian or chirurgion shall declare upon his oath the true value, cost, and quantity of the drugs administered, for which the court shall grant order against the plaintiff with fifty per cent advance, and such consideration for his care, visitts and attendance as they shall judge he hath deserved, and if it shall appeare by evidence that the said phisitian or chirurgion hath neglected his patient while he was under cure, the court shall censure him to pay soe much as they in their discretion shall think reasonable."—p. 109—110.

The preamble of the next act, for the encouragement of the growth and manufacture of flax, gives a woful account of the condition of the great staple commodity of the colony.

"Whereas the incertaine value of tobacco the unstaplenesse of the comodity & and the probability of its planting in other places, threaten this comodity with the danger of an unavoydable ruyne, which must in time fall upon it by the increase of the makers of it amonge ourselves (who have already glutted all marketts that greate quantityes are yearely left in the country, and that which is sent out sold at soe meane and inconsiderable a rate as neither merchant nor planter can well subsist by) unles some other course be spedily taken for the improvement of such other comodityes as the country will produce and making as many of them as we can into manufactures and giveing encouragement unto all persons of what ability soever to attempt it, which the former acts for encouragement to make staple commodityes have been defective in, by only proposing rewards to greate quantityes of every comodity made, when whosoever goes about, must if he faile be ruined, or if he make the quantity proposed will have noe need of the gratuity, which is better to be suited proportionably to the meanest quantity, *Be it therefore enacted* that the assembly this present yeare send into England for a considerable quantity of fflax seed to be distributed into the several counties and delivered to certaine persons who may sell it out to severall inhabitants and the produce thereof to be paid the yeare following with the levye, and the country stock by that meanes be made good, and the several inhabitants be enabled according to the ffiftyeth act of assembly 1661 to make their proportions of fflax, and whoever will spin the fflax and cause the yarne to be weaved into cloath of a yard wide, shall for every yard of cloath soe wove of yarne made of fflax growing in the country have three pounds of tobacco, and for every yard of woollen cloath made of yarne here spun in the country, five pounds of tobacco, which upon the prodnce of a certificate from some justice of peace in the county that he hath seene the same in the loome, and that to his knowledge it was really made in the country as aforesaid shall upon producing the same to the governor and councell be paid soe much in the public levye in the same county where they dwell."—pp. 120-1.

The act to compel the planting of mulberry

* The terminations *tion*, are generally written in the MS. "*con*."

trees, passed in 1656, and which had been revived at the previous session, was, at this, re-enacted at length, with heavier penalties and this additional provision.

"*And be it further enacted* that for the encouragement of all persons that shall endeavour to make silke, there shalbe allowed in the publique levy to any one for every pound of wound silke he shall make fifty pounds of tobacco to be raised in the publique levy and paid in the county or countyes where they dwell that make it."—p. 122.

The next act was designed to encourage the building of vessels, and the manufacture of salt.

"For encouragement of building vessels in this country and the promoting of trade: *Bee it enacted* that whosoever shall build a vessell of any burthen decked and fitted to goe to sea, shall for every tunn burthen the said vessell shall containe, receive upon proofe of her being soe built ffifty pounds of tobacco out of the publique levy.

"Whereas Colonel Edmund Scarborough hath to his perticuler charge but to the infinite good of the country erected a salt worke for which he hath received deserved thanks of the last assembly, This assembly for his greater encouragement have thought fitt to grant him the use of the mony raised this yeare out of the two shillings per hogshead* in Northampton county with condition that he make repayment of the same to those the assembly shall allott it the next yeare in salt at two shillings six pence per bushell, and soap at

"*And be it further enacted* that after the first of September 1663, noe master of ship, barque or vessell or any person merchant or trader shall bring in any salt into the county of Northampton under the penalty of confiscating his ship, barque or vessell, and goods to the end that he and others may be encouraged in their industrious endeavours to promote the good of the country."—p. 122.

The provisions of the next act, to encourage the manufacture of leather, are even ludicrous, for the minuteness and yet palpable insufficiency of the details.

"*Bee it also enacted* that according to the ffifth act of assembly 1660, there be erected in each county at the charge of the county one or more tanhouses, and they provide tanners, curryers and shoomakers, to tanne, curry and make the hides of the country into leather and shoes, and that the person intrusted with the oversight of the workmen, and manageing the trade doe allow to the inhabitants of the county for every dry hide they bring at the rate of two pounds of tobacco per pound, and sell them shoos at thirty pounds of tobacco plaine shoos, five pounds of tobacco for wooden heels and ffrench falls of the size largest sizes, and twenty pounds of tobacco per pair for the smaller shoos, and the county failing herein to be fined five thousand pounds of tobacco."—p. 123.

By the following act, free trade in general is again permitted:

* 'Hundred' in Purvis, 'hogshead' in Northumberland MS.

"*Bee it enacted* that ffree trade be allowed to all the inhabitants of this country to buy and sell at their best advantage, and that all acts concerning ingrossing, be from henceforth repealed and made voyd; *Provided* always that noe person or persons shall have any comerce or trade with any Indians for Beaver, Otter or any other ffurres except those commissionated by the governor." p. 124.

Yet, the two next acts to these are flagrant violations of free trade; the one renewing and enforcing the prohibition to export wool, hides, and iron, and the other to prohibit the exportation of any money, above the sum of forty shillings.—pp. 124-5.

"Whereas oftentimes many brabling women often slander and scandalize their neighbours for which their poore husbands are often brought into chargeable and vexatious suites, and caste in greate damages: *Bee it therefore enacted by the authority aforesaid*, that in actions of slander occasioned by the wife as aforesaid after judgment passed for the damages the woman shalbe punished by ducking; and if the slander be soe enormous as to be adjudged at a greater damage then five hundred pounds of tobacco then the woman to suffer a ducking for each five hundred pounds of tobacco (*a*) adjudged against the husband if he refuse to pay the tobacco."—p. 166.

The following first part of an act, too long to be copied entire, is a curious exhibition of the then prevailing ideas as to the most proper mode to induce the building of a town. A striking instance of the feebleness of legislation, when opposed to nature, is presented in the fate of the town of "James Cittie," for the durable construction of which so much care and such strong compulsory measures were here used. Not a single house of the town now remains standing, nor even one brick upon another, except in the ruins of the old church-steeple, and the wall of the adjacent church-yard.

"Whereas his sacred majestie by his instructions hath enjoyned us to build a towne, to which though our own conveniences of profit and securitie might urge us, yett encouraged by his majesties royall commands, to which in dutie wee are all bound to yeild a most readie obedience, this grand assembly taking into their serious consideration the best meanes of effecting it have in reference thereto enacted.

First. That a towne be built at James Citty as being the most convenient place in James River, and alreadie best fitted for the entertainment of workmen that must be employed in the work.

That the towne to be built shall consist of thirty-two houses, each house to be built with brick, forty foot long, twenty foot wide, within the walls, to be eighteen foote high above the ground, the walls to be two brick thick to the water table, and a brick and a halfe thick above the water table to the roofe, the roofe to be fifteen foote pitch and to be covered with slate or tile.

(*a*) The words 'then the woman to suffer a ducking for each five hundred pounds of tobacco,' not in Northumberland MS.

2*dly*. That the houses shall be all regularly placed one by another in a square or such other forme as the honorable Sir William Berkeley shall appoint most convenient.

3*dly*. That for the better expediteing this worke, each of the severall seaventeen counties build one house, and to that purpose be authorized to impresse in each of the said respective counties bricklayers, labourers, carpenters, sawyers and other tradesmen necessary to be readie at such time as the governour shall think fitt.

"4*thly*. That for avoideing the exaction of workemen, the price of bricks, the wages of workmen and labourers, and their diett at the ordinaryes shall not exceed the prices following, vizt.

"Bricks being statute bricks and well burned, one hundred and fiftie pounds of tobacco per thousand; labourers besides diett two thousand pounds of tobacco by the yeare.

"Brickmakers haveing theire diett and six able labourers to helpe them, provided at his or their charge that employ them, and wood sufficient brought in place for each thousand bricks moulded and burned, fortie pounds of tobacco.

"Bricklayers haveing theire diett and three able labourers to attend each of them, for each thousand of bricks layed fortie (*a*) pounds of tobacco.

Carpenters per day besides theire dyett thirty pounds of tobacco.

Sawyers for boardes and summers one pound of tobacco per foot, for timber for joyce, windowes, door cases and rafters, principalls, purloyners and other smalle timber, the said sawyers finding themselves and labourers dyett, halfe a pound per foot in length."—p. 172.

More legislation in regard to mulberry trees was thought necessary at the session of 1663.

"Whereas there hath been an impossibility of procureing soe many Mulberry trees as every proprietor of land is by act of assembly enjoyned to plant for his proportion, being ten trees for every hundred acres; this grand assembly takeing the same into their consideration *have therefore enacted* that the time shalbe respited for three yeares longer, vizt. untill the last of December, 1666, and that whoever shall then be defitient shall for every tree wanting be fined twenty pounds of tobacco being double the fine already imposed."—191.

"George the Armenian having proved the making of ten pounds of wound silk it is ordered there be paid him for his encouragement in the levy according to act.

"John Dolby procuring certificate that he had made and wove nineteen yards of woolen cloth in Northton county, the assembly hath ordered him the encouragement according to act being tobacco.

"John Pitte producing certificate that he had built a vessel of 28 tuns in the Isle of Wight county, the assembly ordered him the encouragement of accordingly."—p. 199.

Among other "Propositions humbly presented to this honorable assembly" was the following:

"That the act for planting of mulberry trees may be repealed it being very prejudicial to such as want clear grounds and are not in a capacity at present to fulfill the same without great prejudice, and it is humbly conceived that (if it be beneficial) men as they find themselves in a capacity will fall upon it without constraint,"—p. 202.

The following are the general and material parts of "an act for a cessation" of the cultivation of tobacco for a limited time, passed in 1666. This was a favorite policy, both with the government and the people. But though it was often attempted to be put in force, it was to little advantage, from the non-concurrence of Maryland and North Carolina, as well as for more general and sufficient causes.

"Whereas the quantity of tobacco made in this country by encrease of the number of inhabitants imploying themselves wholly to the makeing that comodity, and their continued ffreedome of their unlymitted planting is become soe greate that all marketts have beene glutted with itt, and the value of it reduced to so low a rate that the planter is rendred incapable of subsisting, the merchant discouraged in his trade, and consequently by the decay of trade his majesties customes impaired, while the tobacco that formerly releived the planter, encouraged the merchant, and augmented the custome, both now and some yeares past did and doth rest perishing on the planters account, to his utter undoeing; the remedy of which inconveniencies the governour, councell and burgesses of this assembly takeing into their serious consideration, have found that the most proper and effectuall course to effect the same wilbe by enacting for one yeare a cessation from planting, In which vacant yeare time wilbe given to the planter to settle himselfe upon the finding out and improvement of some other staple (as wee have already begun in silke, fflax, and potash) the merchant encouraged to give a better price when he shalbe assured to have tyme to vend it, and his majesties customes noe way diminished, since the exportation of all the tobacco already made, and likely to be made this next crop, will in all probability (notwithstanding the cessation) equall the quantity of that which hath beene in the like tyme exported; ffor which consideration often message hath beene sent from the assembly of Virginia to the lieutenant generall of *Maryland*, to establish a stint or totall cessation from planting in both governments who have communicated the same to the assembly of that province, they being equally sensible of their pressures, have enacted a cessation with provisoe of the concurrence of this country of *Virginia* and *Carolina*, ffor which causes *it is thought fitt to enact, and be it enacted by the governour, councell and burgesses of this present grand assembly and the authority thereof* that from and after the ffirst day of ffebruary which shall be in the yeare of our Lord 1666 till the ffirst of ffebruary which shalbe in the yeare of our Lord 1667, noe tobacco shalbe any wayes sowne, sett, planted, or tended, directly or indirectly within the government of Virginia," &c.—p. 224-5.

The next is another example of misdirected attempts to encourage industry.

"Whereas the present obstruction of trade and

(*a*) 'Fifty' in Northb. MS.

the nakednes of the country doe suffiiently evidence the necessity of provideing supply of our wants by improveing all meanes of rayseing and promoteing manufactures amonge ourselves, and the governours honour haveing by apparent demonstrations manifested that our poverty and necessity proceeds more from the want of industry then defect of ability, since that five women or children of 12 or 13 yeares of age may with much ease provide suffitient cloathing for thirty persons, if they would betake themselves to spinning, which cannot be objected against, if weavers and loomes were once provided; for the better effecting whereof, *Be it enacted by the authority of this grand assembly* that within two yeares at furthest after date of this act, the commissioners of each county court shall provide and sett up a loome and weaver in each of the respective counties of this country, at the charge of the county, and that noe private person setting up a loome at his owne charge shall excuse the county from setting up a publique one; But that every court neglecting to performe the tenour of this act shall be fined two thousand pounds of tobacco to the use of the publique and informer. *Provided* that the executing hereof in the counties of *Rapahanock*, *Stafford*,* *Westmerland* and *Northumberland* who by the newnesse of their ground pretend themselves incapable of makeing provision for the soe soone imployment of a weaver be respited for fowre yeares after the date hereof."—p. 238-9.

The next act repeals all prior acts for encouragement of silk, and other commodities, not upon the ground of their inefficacy, but for reason that they had so operated as no longer to be necessary. This assertion is not sustained by other evidence, and may well be refused credence.

"Whereas the providence and care of the publique good in former assemblies thought fitt for the advance and promotion of trade, manufactures and staple comodities in the country, to grant of the publique certaine encouragements for building of vessells, makeing of silke, cloath, &c. By which meanes diverse people being induced to put the same in practice, have by their successe made evident demonstrations how beneficial the same will prove; This assembly in hopes that all people now convinced of the profitts accrewing thereby will of theire owne accords vigerously prosecute those now apparently profitable designes, have therefore for the ease of the publique taxes *thought fitt to enact, as by this grand assembly and the authority thereof, it is enacted*, that all acts of encouragement of silke, cloath, building of vessells or any thing else may henceforth be generally and totally repealed and voyd, except the act for release of the impost of two shillings per hogshead to inhabitants of this country adventuring in vessells belonging properly and solely to Virginia owners, according to the one hundred and thirty fourth act of assembly; And moreover that the act imposeing a fine for not planting of mulberry trees which every one intended to make silke will now propagate voluntarily, be also repealed and made voyd."—pp. 241-2.

(*To be continued.*)

* This is the first time the name of *Stafford* occurs among the counties. In Mercer's abridgment, title 'Counties,' it is said to have been established in 1675.

To the Editor of the Farmers' Register.

Murfreesboro' N. C., Dec. 1, 1838.

Lately meeting, in a copy of the "Courier des Etats Unis," with a communication read in the French Academy of Sciences, by M. Roulin, on a subject which comes within the sphere of agriculture, I have thought that I might at least interest if not instruct your readers, by sending you a translation of it for publication in your valuable periodical. Should this be favorably received, I may possibly send you others during the winter.

B. S. W.

THE CHANGES UNDERGONE BY DOMESTIC ANIMALS ON BEING TRANSPORTED FROM EUROPE TO AMERICA.

Being part of an essay on that subject, read in the French Academy of Sciences, by M. Roulin, and translated for the Farmers' Register.

The observations of our author on this subject were made during a residence of six years, in a part of Colombia, extending from the third to the tenth degree of north latitude, and from the 70th to the 80th degree of west longitude. Although this space is limited, it offers a field very favorable for observations of this character; being traversed throughout its whole extent by the great chain of the Andes, divided here into three smaller branches, so that animals fitted for a temperature of ten degrees, (Reaumur) and those for a temperature of thirty degrees, may be found within a very short distance from each other.

Has the establishment in these regions of animals, transported from Europe, been attended with any remarkable phenomena? Once naturalized, do they remain, as they were in Europe? If they have undergone any permanent change, may not this new transformation throw some light upon that which they have formerly experienced in passing from the savage to the domestic state? These are the questions which would naturally present themselves to the student, and for the solution of which the author brings a great many facts relative to the different species.

The Mammiferæ.

The animals of this class, which have been transplanted from the old to the new world, are the hog, the sheep, the goat, the ass, the horse, the cow and the dog. These have become at this day much more numerous in the new continent than all the large native quadrupeds.

The HOG, considered as an occupant of warm valleys, or as roaming through the forests and seeking wild fruits, which, at certain seasons, compose his whole food, has passed almost all the marks of his domestic state. He has become again half-wild. In 1493, one year after the discovery of America, the first hogs were introduced into this country, in the island of St. Domingo. In succeeding years, they were carried wherever the Spaniards settled, and in the space of half a century, were established from the 25th degree of north latitude, to the 45th of south latitude. They seemed to suffer nothing from the change of climate, and from the very commencement were raised with the same facility as in Europe.

The naturalization of CATTLE presented difficulties of a more serious kind, which, however, were conquered by the admirable perseverance of the first colonists. The island of St. Domingo, where these animals were first introduced, became a sort of nursery, where they multiplied prodigiously, and whence were drawn vast herds to stock the different parts of the mainland, the coast of Mexico, and the interior. Oviedo tells us, that, in spite of this immense exportation, herds of 4,000 cattle were very common in that island, only 27 years after its discovery. Herds even of 8,000, were sometimes to be met with; and, according to Acosta, in 1587 the exportation of hides from the island of St. Domingo, alone, amounted to 35,444. In the same year, were exported from the different parts of New Granada, 64,350. This was the sixty-fifth year from the conquest of Mexico, an event, previous to which the Spaniards had been engaged in nothing but war.

As soon as cattle were multiplied to such an extent as to become almost wild, it was discovered that a certain quantity of salt was indispensable in their food, and that, if they did not get this salt from the herbs, the water, or certain earths of a brackish taste, which exist in many countries, they became lean, the females were less fruitful, and the species rapidly degenerated. In those places where there is a sufficiency of salt, the inhabitants find an advantage in giving some to their cattle, as, besides its beneficial influence on their health, this practice accustoms them to come up at a fixed hour to the place where they are usually fed, and where they know they will find salt. If these regular calls be neglected, it is no wonder they soon disperse and become wild.

In Europe, where milk is regarded as a very important part of the produce of the dairy, the cow is milked, from the moment when it becomes capable of propagating its kind, until the time when it ceases to be so. This plan, constantly exercised on every individual during a long series of generations, has ended by producing important alterations in the species. The teats have become of immense size, and the milk continues to flow from them even when the calf is taken away from the mother. In Colombia, a train of circumstances, useless to mention, have contributed to produce very different results; but only a few generations are necessary for this animal, left in liberty, to return to her original organization. For the cow to preserve her milk, it is necessary, in Colombia, that the calf be with her the whole time, and be able to suck. If it be taken away only for one night, nothing is gained by the milk which is collected during this interval; for as soon as the calf ceases to suck, the milk immediately dries up.

The ASS, in those provinces in which M. Roulin had opportunity to notice it, appears to have undergone only some slight alterations in its form and habits. In some places, where little care is taken of this animal, and where it is overworked, it is not unfrequently born deformed; but in none of the provinces visited by our author has it ever become savage.

The same observations do not hold good with respect to the HORSE. From the wild and independent life of the horse, a uniformity of color arises peculiar to the untamed species. The chesnut is not only the prevailing, but almost the only color of this animal.

The gait preferred in saddle-horses, is either an ambling or a stately gait. Pains are taken and kindness is employed, in training the animals to either of these motions that may be preferred. Whilst they are undergoing this system of discipline, they are not permitted to move in any other gait. After a certain time, the horses contract these motions habitually, and if they are of a beautiful form, they are let go in the forests to propagate their breed, as very few of them are ever gelded. From these result a race of horses in which the amble, among the full grown ones, is as natural as the trot among other horses. These are called *aguillillas*.

DOGS were transported into America, during the second voyage of Columbus; and it is worthy of remark, that in his first battle with the aborigines of St. Domingo, he had, in his little army, a pack of twenty blood-hounds. This animal was afterwards employed in the conquest of different parts of the continent, especially in Mexico, and New Grenada. The race is still preserved without apparent alteration, on the table-lands of Santa Fé, and is there used for hunting the stag. It displays, in that region, extreme ferocity, and employs the same mode of attack which formerly rendered it so dreadful to the native inhabitants. This consists in seizing the animal when in full career, under the lower part of the belly, and in overturning it by a sudden motion of the head, taking advantage of the moment when the whole weight is suspended upon the fore-legs. The weight of a stag thus thrown to the ground, is frequently six times that of the dog.

Certain dogs of a pure breed inherit, without instruction, the necessary instinct for the chase of the peccasy, (Peruvian hog,) in which they are often employed. The art of the dog consists in restraining his ardor, in never attacking any particular animal, but in holding the whole herd at bay, without permitting himself to be surrounded. One dog, the first time he is carried into the woods, attacks the herd in the most advantageous manner; another rushes indiscriminately upon the whole herd, and whatever may be his strength, he is devoured in an instant.

The species of SHEEP transplanted into America, is not the Merino, but two kinds, called in Spanish *lana basta y burda.*

The sheep propagates very well in temperate climates, and in no part shows any disposition to forsake the authority of man. In the burning climate of the plains it is maintained with more difficulty; but its existence there gives rise to an extremely curious phenomenon. The wool of the lamb grows almost like the wool produced in more temperate regions, with the single exception, that it requires a longer time to mature. When the animal is in the proper state to be sheared, the wool presents nothing remarkable in respect of firmness, and if it be then taken from the lamb, it commences growing again, and every thing proceeds just as among the sheep of more temperate countries. But if, in this warm climate, the shearing season is suffered to pass away, and the fleece left on the lamb, the wool thickens, becomes like felt, and finishes by detaching itself from the body, leaving under it not a new growth of wool ready to spring up, nor a naked and diseased skin, but a short, fine, shining, velvety nap, very similar to that of goats, reared in the same climates. On those spots where this nap or hair has once appeared, wool never again grows.

The GOAT, though its form is evidently that of a native of the mountains, accommodates itself much better to the low and burning valleys, than to the elevated parts of the Cordilleras. Not being milked so often, it has not those large teats which render it so remarkable among us. In this animal, a change may be observed analogous to that which we noticed in the cow.

Birds.

Among the bird-tribe, very few changes have occurred. The DOMESTIC FOWLS present little or no difference from those of Europe. But in warm countries, and among the acclimated species, a remarkable anomaly presents itself. Chickens, whose parents have lived for a great number of generations, in a medium temperature, above 28°, (Reaumur,) are hatched with but little down upon them, lose that little very soon, and for more than two months have no feathers except on the wings.

Chickens not acclimated, (and twenty generations are not sufficient to acclimate them,) cherish their first down as if they needed it. How many years, asks our author, must have been required to have effected this very sensible change in their organization?

The common hen has thrived very well in most of the islands in which it was first introduced by the Spaniards. But in some higher regions, as at Cuzco, and throughout the whole adjacent valley, great difficulty was found at first in propagating it. By care and perseverance, however, some chickens were obtained. These were by no means fruitful, but their descendants have become extremely so, and at this day they propagate with the same facility as in our climates. The same phenomenon appears to have taken place with the GOOSE, which has only within a few years been introduced into Bogota. The PEACOCK, the SPECKLED-HEN,* and the PIGEON seem to have undergone no change. The first has even preserved the variety of colors for which it is distinguished in Europe.

Conclusions. Although the foregoing observations have not been made by the author for the support of any particular system, it seems to us that we may very naturally deduce the following inferences: First, that species must be acclimated as well as individuals. Second, that domestic animals, left to themselves, have a great tendency towards the organization of those of the same species which we observe in the savage state, and that a very few years sufficed to effect this transformation.

[The further contributions of the translator of the foregoing article, will be thankfully received. ED. FAR. REG.]

From the Agricultural Magazine.

AN ACCOUNT OF AN IMMENSE CHIMNEY, RECENTLY BUILT AT CARLISLE.

"The immense chimney attached to the new cotton factory, now being built for Messrs. Peter Dixon and Sons, in Shaddongate, had the last stone placed upon it on October 24, 1837. It is one of the highest buildings in England, being 305 feet from the ground; and for the purpose to which it is to be applied, is understood to be the highest erection in the world. It may be distinctly seen for many miles in all directions around Carlisle, and forms a beautiful object in the view of our city, from whichever quarter you approach it. The building is of the octangular form, and is built with brick, the angles being formed of stone. The base, which is built with fire-bricks, is 17 feet 8 inches in width inside, and the thickness of the wall at the foundation is 10 ft. It tapers upwards to a width, inside, of 6 ft. 3 in.; and on the outside 8 ft. 9 in. Near the top there is a cornice of stone, 7 ft. in depth, which projects 3 ft., and above this there are 8 ft. 3 in. of brickwork, surmounted by a coping stone one foot in thickness. The cornice gives a finished and classical appearance to the building; and the whole would be taken for some splendid national monument, rather than a mere conduit pipe for smoke. It is not a little creditable to Carlisle, that this magnificent work was entirely executed by a native of that city, a builder, a Mr. Richard Wright, who has completed it in the way to give the most entire satisfaction to every scientific man who has examined it. Considering its immensity, the work was completed in an incredible short period of time. The foundation stone was laid on Sep. 11, 1835, by P. Dixon, Esq.; the first brick was laid by Mr. Wright, on Sep. 17.; the last course of bricks, also by Mr. Wright, on Oct. 22, and the last coping stone on Oct. 25, 1836; thus completing the work in thirteen months. The erection was carried on from the inside, stages being erected as the work proceeded, and the workmen and materials being taken up in boxes prepared for the purpose, by a crab worked by four men; and it is gratifying to add that the whole was finished without any accident occurring to any individual engaged in it.

THE MILK SICKNESS, AND THE BOHAN UPAS OF THE WEST.

The mysterious disease which bears this name, is peculiar to the region west of the mountains, and prevails only in certain districts of that region. Many parts of Kentucky, Indiana, Illinois and Missouri, have been greatly afflicted by it, hundreds have died its victims, and some districts of country are almost uninhabitable on its account. The Kentucky legislature has long since offered a reward to any one who could ascertain the cause of this terrible disease, but all inquiries upon the subject have been hitherto unsuccessful. The St. Louis Bulletin, however, contains a letter on the subject, said to be from the pen of an intelligent gentleman, in which the cause of the disease is referred to a tree, the properties of which are described to be very similar to those attributed to the Bohan Upas of the East Indies. The letter, which will be found interesting, is subjoined:

Femme Osage Township.
St. Charles Co., Mo., Nov. 9, 1838.

Mr. Koch—Dear Sir—I herewith transmit to you one of the genuine apples of Sodom. It grew on a large Sodomite tree in Femme Osage bottom, in St. Charles county. The tree is nine feet thick, one hundred and forty feet high, and straight in the body, there being no limbs for forty six feet above the ground. In a fruitful year

* Pintada, or Guinea fowl?—ED.

it is estimated that it bears one-thousand bushels of fruit. The leaves resemble those of a pear tree, but are much larger and evergreen; the blossoms are similar to the tulip. and when in full bloom, it is considered the most grand, beautiful and imposing object in the vegetable kingdom. But it is of the most poisonous nature; its roots, bark, sap, leaves and fruit, are all destructive poisons. Its twigs and branches operate as a slow, malignant and incurable poison, of a peculiar quality, destructive of animals and man. It has been recently discovered, and satisfactorily tested, that the browsing upon the sprout about its root, is the cause of that mysterious disease, called the milk sickness.

The fruit, when full ripe, has an inviting appearance, but it soon takes a dry rot, and the inside becomes a poisonous and disagreeable dust, in appearance resembling Scotch snuff. Notwithstanding its noxious qualities, cattle and various other animals are fond of frequenting it and feeding on its leaves, and they frequently die in its vicinity. Numerous skeletons of animals may be found in the bottom, within a mile round, but when taken in small quantities, it terminates in lingering and uncontrollable milk sickness. Since the tree has been fenced in, no milk sickness has existed. The wood of the tree is as solid and heavy as lignum-vitæ or ebony, and from its similarity, some intelligent persons have conjectured that is the celebrated tree called the Bohan Upas in the East Indies. When any part of the green tree is lacerated, a peculiar gum exudes from the wound, like unto white native turpentine, which is esteemed one of the strongest poisons, and will blister and seriously injure and ulcerate the human body if applied externally.

It is thought by some persons that this tree might be advantageously used in the practice of medicine if its powerful medical qualities were properly understood, but its poison is so destructive that every person here is afraid to make any experiments with it. If the citizens of those parts of Illinois, Ohio and Kentucky, that are afflicted with the milk sickness, will make proper examination, I have no doubt that they will find somewhere in the sick district a solitary tree similar to the one I have described above, and if they will destroy or enclose the tree, they will effectually prevent the disease. Many marvellous stories are told in the neighborhood, but respecting many of them I am very incredulous; but the foregoing statement I have prepared from personal observation, and from information in which I could place implicit confidence. If you should desire further information respecting this tree, I will take pleasure in answering any inquiries directed to me by mail, to Missouri town, my nearest post office.

With great esteem,

Your obedient servant,

———.

IMPROVEMENT OF LAND BY MANURING WITH MARSH-MUD, MARSH-GRASS, SEA-WEEDS, SHELL BEDS, &c., &c.

[The following connected papers, which appeared in the American Farmer of 1831, are republished here, both on account of the interesting contents of the correspondence, and in the hope of drawing forth, from the same or other sources, additional and more recent facts, on any of the same subjects. In "Potomac," we recognize, by internal evidence, one who has since been a highly valued contributor to the pages of the Farmers' Register; and whose contributions exhibit proofs of the profit which he derived from this earlier correspondence, when a "novice" and a mere seeker of information. We know not who is the writer of "Corn-planter;" but if he is not already one of our contributors, his becoming so is much to be desired; and especially from him, or others, is wanting, and would be of great use to many readers, the fullest and most recent information on the use of marsh-mud, as manure.

It is astonishing that so little has been yet done, and so much less made generally known, in the use of marsh-mud as manure. It is true that hundreds of writers recommend the mud of ponds, ditches, marshes, &c. as ingredients for compost heaps, or for the foundation of, or for mixing with barn-yard manure; and very many speak, generally, but as from experience, of the profitable results thence derived. But still, there is an utter deficiency, so far as we are informed, of any precise and satisfactory statements or estimates, of the amount of profit, or of increased products, obtained from the application of any certain quantity of marsh-mud, or of expense in its use. And the few applications which we have known of, including some of our own, of the mud applied alone, have not produced such apparent increase of early product, or of fertility, as to encourage the repetition.

Still, reason and theoretical views would strongly recommend the very extensive use of marsh-mud, both for its great available quantity, its cheapness in application, and for the value of the fertilizing ingredients which it certainly contains, (and indeed mostly consists of,) and must give to the soil. A very simple and yet sure mode of analysis, (by fire,) which we have often used for this purpose, will prove to any experimenter, that about one half of the dry weight of all common tide-marsh-mud consists of vegetable matter; and that part, when dry, is so very light, that what serves to make half the weight, is probably nine-tenths of the entire bulk of any given quantity of the mud. All vegetable matter, finely broken down and much decomposed, as this is, would be supposed to be manure, and of a kind ready for speedy action; and if not so in this case, it cannot be for want of richness, or on account of the deficiency of the elements of food for plants in the mud; but because the vegetable matter therein is not in a state to serve as food for plants. This is the case with peat, which is almost entirely a vegetable substance, but of vegetable matters made insoluble, and therefore incapable of acting as manure, and feeding growing plants. Yet peat may be rendered soluble, and made a valuable material for compost manure, by being mixed with and acted on by highly putrescent manure, by alkaline fluids, and by quick-lime. Now it is possible, that though our marsh-mud is very far from being incapable of rotting, still its being so long water-soaked may have taken out all the soluble parts, ready for immediate action; and that composting with other substances, as is recommended for peat, may be required to bring the balance of the mass into early and profitable use. Several things give countenance to this supposition. The only known cases of the marsh-mud being supposed profitable, were when it was used in mixture or union with other manures; or when it was from salt-marsh—the salt perhaps serving in some measure for the same purpose. In addition—and it is the most important circumstance—the readers of this journal may remember the French practice (stated in Puvis' Essay on Lime, vol. 3, Far. Reg.) of applying lime in quantities as small as 5 bushels to the acre, with profitable effects. But this lime was put in compost, with rich vegetable soil, which is much like marsh-mud in composition, and it was stated that the older the compost, the better its operation as manure. Now, as the lime could not grow stronger or richer by age, it may be inferred that it was the mass of vegetable matter, acted on slowly and gradually by this small leaven of quick-lime, which was improving in value, and which in fact constituted the greater strength of the compost as a fertilizer. If by any means, this enormous and inexhaustible supply of natural material can be profitably used as manure, it would be the greatest means for improvement, except calcareous manures, yet offered to the tide-water region. Nor would it be confined to that region; for others have rich alluvial and vegetable deposits, in swamps and in the bottoms of ponds, to which the same rules and practices would apply. And if the state government should attempt to aid agricultural improvement, there will be few subjects for experiment more worthy of being directed, and paid for, by the state, than the conversion of some portion of this widely spread and now unmixed evil and nuisance, to a source of fertility and profit, as manure for the neighboring lands.—Ed Far. Reg.]

From the American Farmer.

Westmoreland county, Va.
August 11, 1831,

Mr. Smith—I am engaged in making extensive experiments with marsh-mud, Indian banks, or partially decomposed oyster shells, which are found in great abundance on the margins of many of our creeks, and kelp or sea-weed, which is thrown in great quantities upon the shores of the Potomac, by almost every tide. These abundant and convenient resources for fertilizing our lands, have hitherto been almost totally neglected by the farmers in this part of the country; and in making my experiments I am entirely unaided by the results of the experience of others. In applying the marsh-mud, the plan recommended by Judge Johnson of South Carolina, in 11th vol. of the American Farmer, has been pursued, and I have no doubt will be successful. The partially decomposed oyster shells have been applied in the manner in which marl is used in different parts of the United States. In the application of the kelp I have experienced more difficulty, having been unable to find any practical treatises upon that subject. To my surprise, although this manure has been used with great effect as I have been informed, for many years, in different parts of Maryland, there is not a line to be found in the American Farmer upon this subject, with the exception of the communication from Thomas Griffin, Esq. of York Town, Virginia, contained in the first volume of that valuable work. A practical essay upon this subject, by some intelligent agriculturist who has used this manure extensively, would be of vast service to the farmers upon the sea-board, and upon the salt-water rivers, where this valuable "*weed*" may be obtained in almost inexhaustible quantities. I should be much gratified by information particularly upon the following points. What is the best season for applying the sea-weed? Is it most efficacious when applied in summer, winter, or spring? Should it be applied fresh as taken from the river, or after standing in heaps until partly decomposed? Is it true that wire grass is introduced by its use? Should it be turned in immediately, or left upon the surface until the earth is tilled for a crop? The plan which I am pursuing, is to distribute the weed regularly in the water furrows of an old cornfield, as soon as convenient after it is carted out, and to list immediately upon it, to protect it from the rays of the sun. I put from 70 to 100 loads, drawn by two yoke of oxen, upon an acre.

Since the beginning of the present year, I have kept a cart, a man and a woman, and two small boys who could do nothing in the field, constantly engaged in collecting and carting out manure of various kinds, and at this time, which is a season of comparative leisure with farmers, I employ an additional cart, and a few additional hands, and with my short experience I can confidently say that the labor thus employed is ten times more productive, than it would be in any other work upon the farm. I yesterday stood by for two hours where my carts were carrying kelp from the river shore, and in that short time twenty-one loads, averaging about 20 bushels, were carried out. The distance of course was short, and the kelp abundant, so that little time was lost in loading. I have little doubt that with the force exclusively devoted to this business, and with occasional assistance from the farm hands, I shall be able to manure at least one hundred acres annually. This may be startling to those who have paid little attention to the improvement of the earth, but it is not more incredible than the account given by Mr. Singleton of the Eastern Shore of Maryland, in the 2d vol. of the Farmer, of the great improvements effected upon his farm, with comparatively limited means. The accuracy of that account I was at one time disposed to question; I am now thoroughly convinced of its truth. You may find some valuable information upon this subject of kelp as a manure, in the 1st vol. of the New Edinburgh Encyclopædia. Art. Agriculture, page 270, by transferring which to your columns, you will probably benefit your readers.

When my experiments are sufficiently matured to enable me to afford any useful information to the public, I may trouble you with a communication under my proper name; but for the present, being merely seeking information from others, I subscribe myself your obedient servant,

POTOMAC.

SEA-WARE, MARSH-MUD, ETC.

Talbot county, Eastern Shore, Md.
August 30, 1831.

Mr. Smith—Sea-ware is thrown on our shores in considerable quantities, and we have had numerous banks of partially decomposed oyster-shells, but they are now nearly exhausted. Many have made their lands rich by the application of these materials, and the more modern ones—marsh-mud, and the heads of creeks. It may be encouraging to "Potomac," and such of his neighbors as have the good fortune to possess these precious treasures, to know that the annals of this county afford instances of more rapid improvement from them, aided by well managed farm-yards, than that mentioned by the late Mr. Singleton from shell-marl. That nothing has been written on the subject in this quarter is owing to the general knowledge of their value:—the time for experiments in regard to them has gone by. They have been used extensively for thirty years—partially, much longer.

One good dressing of Indian bank shells is *sufficient.* The sea weed may be applied with advantage to every new crop:—they act together better than separately—and better still combined with stable or farm-yard manure. But it cannot be expected that all this can be effected, to any considerable extent, in one year—if done in the regular course of cultivation it will be sufficient. That is, give a dressing of marsh one year, and one of shells the next time it is cultivated—or the reverse. My experience and observation lead me to recommend that the shells be dropped on every fourth or fifth *land*, or ridge, as near to each other as convenient to the carter; that is—when his team arrives within a few feet of the load just deposited let him tilt his cart. The same process to be observed in dropping the sea-ware. This valuable article acts well on all crops, and at all seasons—the sooner it is turned in the better: it loses much of its virtue by exposure—but it is a common practice to drop it during the summer on land intended for corn next year, where it lies until it is time to *list.* It is excellent for fallow. When thrown on shore by a favorable wind the most pressing jobs are postponed until it is secured, either by taking it to the field where wanted, or by heaping it a few feet above high-water-mark, to prevent its being carried off by the ebb tides. It is useless, and double labor, to put it in large heaps—if heaped in the field, in large bulks, nothing will grow on the spot it occupied for several years:—indeed a single cart load, if it lies a few months, deposits rather too much salt—to obviate this one of my neighbors distributes it in half loads. No instance is known of its introducing wire-grass or any other pest.

Marsh-mud and the heads of coves are now extensively used. Unexpected quantities and qualities of manure are frequently found:—after penetrating through a stratum of rich salted alluvial soil, well rotted marsh, emitting a strong stench, is often found. These *compost-beds,* from *six to ten feet* deep, of the best *materials* ready *to our hands*, are invaluable. Some of our landholders, who let land on shares, are so sensible of the value of these resources that they furnish a cart, team and carter, (the tenant finding food,) to be employed on them exclusively all the year. Marsh can be got out in the dead of winter—it makes an excellent dressing for the farm-yard. Oyster-shells, collected from bars by men who make a business of it, in large quantities, are sold at $1\frac{1}{2}$ to three cents per bushel to farmers, who burn them in kilns made of pine logs. The lime, and half burnt shells, are spread with shovels from the cart tail, at the rate of 150 to 200 bushels per acre, just before or after planting corn—or before seeding wheat.

Indian banks should be dug with grubbing hoes, or (if the ground will admit) ploughed up, and *shovels* used in loading. Iron pronged forks suit the sea-weed, *spades* and shovels the heads of coves and marshes. From two to five carts should be run, so that the hands employed to load may have constant work. *Single* teams are preferred.

I am no *essayist;* but hope something useful may be found in the above.

CORNPLANTER.

SEA-WEED, ETC.—MANURE.

Westmoreland county, Va.
Sept. 17, 1831.

Mr. Smith—I have to return my thanks to your correspondent, "Cornplanter," for the prompt and obliging manner in which he has responded to the inquiries made by me in my last communication. I am much instructed, and encouraged in the course which I had determined to pursue by the facts which he has disclosed. But I am a young and inexperienced farmer; and most of my time, moreover, being devoted to public and professional pursuits, I have but little opportunity, except in occasional intervals of leisure, of attending to the practical details of agriculture, or of acquiring by personal observation that minute knowledge, which is so essential to successful husbandry. Your correspondent will, I hope, therefore, excuse me, when I ask, not only for my own instruction, but also for the benefit of some of my neighbors, who are equally uninformed, and have, moreover, inveterate prejudices to subdue, that he will favor the public with another essay, in which more detailed information may be given. I have, myself, not the least doubt of the accuracy of the statement that there are instances of more rapid improvement on the Eastern Shore of Maryland, from the use of sea-weed, marsh mud, and Indian banks, than that afforded on the farm of the late Mr. Singleton, from shell marl. But there is no subject, on which there is so great a disposition to be incredulous, as in relation to agricultural improvements. And it is owing, in a great measure, to this very incredulity, that whilst improvement in the mechanic arts, and in the liberal sciences, and indeed in almost every other department of life, is rapidly advancing, agriculture, the most indispensable of all arts, is in many parts of the country completely stationary. As an instance of this incredulity, I may state the fact, that when I commenced digging in the marshes for manure, I was regarded by my neighbors as a visionary enthusiast, equally as mad as one who should seek for perpetual motion, or the philosopher's stone. The negroes were amazed; the overseer expressed serious apprehensions that the land would be *killed;* and one of the lights of the neighborhood in agriculture, completely confirmed his fears, by telling him that *he* had tried it, and he had enough "dead land" already, without attempting to "kill any more." It was in vain that I quoted the high authority of the American Farmer, and Judge Johnson; nothing could convince them of the efficacy of marsh-mud. I had the satisfaction, however, in the course of about two months, of seeing prejudice and incredulity completely subdued. Upon visiting my farm, I was met by the overseer with a smiling countenance, and informed that he was beginning to be convinced that the mud might be of some service; for the weeds were much higher upon the land where the mud had been put, than upon that adjacent to it, which was originally much better. And upon visiting it, a few days ago, I found him entirely convinced by a thick growth of crab grass, upon the land covered with the "marsh," whilst the surrounding vegetation was much less luxuriant.

But to return from this digression; your correspondent may remove the doubts that are now entertained, as to the practicability of manuring on an extensive scale, and perhaps stimulate to exertion many who are slumbering in indolence by stating the extent of the improvement effected upon a few particular farms, by the use of the means referred to; the condition and quality of the soil before the improving process was commenced; the amount of labor and capital expended; the crops made upon the land formerly, compared with its present productions; and whether the use of these means is supposed to have had any *peculiar* effect in adapting the soil to the growth of the beautiful white wheat for which the Eastern Shore of Maryland is so justly celebrated. This information in the community in which he resides may seem entirely unimportant, but he may be assured that to a large portion of Eastern Virginia, it is calculated to be of vast service. We have here a soil originally fertile, but much impoverished by a long course of barbarous cultivation. The means of resuscitating are at hand, if the public attention were only turned to them. And no greater service could be rendered to the cause of agriculture, than to convince the farmers in this part of the country of the natural advantages which they possess. They would thus be urged, if not by necessity, yet by reason, to exertion; with the hope not only of securing a competence, but of accumulating wealth, and by the desire which the loftier considerations of patriotism might inspire, of improving, fertilizing, and adorning their native land.

I fear that I have trespassed too far already upon the politeness of your correspondent, but I must ask information on one other subject. Can the "rotted marsh" found in the natural "compost beds" of which he speaks, be applied with safety or advantage immediately to a growing crop? Or does it require exposure to the atmosphere before it is fit for application? I am induced to make this inquiry because, in pursuing the instructions of Judge Johnson, in relation to marsh mud, I had applied a quantity of this "compost" (of which I have inexhaustible beds) early in the summer to land which I intended to *fallow* for wheat, and I was surprised to find, contrary to my expectations, that the vegetation was greatly advanced, almost immediately upon its application, and at this time the land exhibits unequivocal indications of very great improvement. I was led to infer from this circumstance, that Judge Johnson's instructions might have reference to a subject entirely different; and reasoning from analogy I concluded that this manure might be beneficial, when applied fresh to growing crops. But all arguments from analogy are more or less fallacious, and I should be much better satisfied with the experience of your practical correspondent.

POTOMAC.

MARSH-MUD, ETC.

Talbot county, Eastern Shore, Md.
October 12, 1831.

Mr. Smith—I do not know how I can more satisfactorily answer the polite call of "Potomac" than by giving some account of improvements made on one of the farms alluded to in my last, by the application of bank-shells, sea-ware, marsh-mud, and heads of creeks, aided by a well conducted farm-yard. These have been so remarkable as to have had a beneficial effect in this county, and I think such examples should be made known as widely as possible for general benefit.

I select this farm, *Emerson's Point*, in particular, because no one can pretend that *capital* had any agency in restoring its fertility. It lies near the mouth of Mile's river, emptying into the Eastern-branch of the Chesapeake bay, and contains two hundred and seventy-five acres. It was purchased by the father of the present proprietor, Mr. Wm. Hambleton, about the year 1790, at 40s. Md. currency—5.33 dollars, per acre,—and was occupied by a tenant, as it had been for two or three generations, until the year 1808, when the proprietor married and settled on it. The soil is a stiff yellow clay—growth chiefly pine; it was worn down to the lowest state of sterility: a considerable portion had been suffered to run into pine thickets, where the corn ridges are still visible; and it was nearly destitute of the buildings indispensable to a farmer. But the means of improvement were at hand: the proprietor knew their value, and lost no time in availing himself of them. He had *no capital* of any kind: but he was young, skilful and industrious. Having no slaves he commenced with two hired hands, and, occasionally, two boys, two horses and a yoke of oxen. The arable land was one hundred and twenty-nine acres, but his operations, for many years, were confined to ninety-nine acres—a poor field of thirty acres, distant from his resources, he left idle, unenclosed. He laid off these ninety-nine acres as follows:—two fields of 45 each, two lots, 5 and 1½, orchard and garden 2½ acres. For his first crop, to make a *push*, he selected his best land, including the old tobacco ground near the house. From forty-five bushels of wheat seeded Sept. 1807, he got a crop of one hundred and fifteen, less than three for one. In the spring of 1808 he planted corn on one half of his other field, after getting out a considerable quantity of bank-shells and sea-ware, and left the other half, *under the same enclosure*, for fallow, to be manured as opportunity might permit during the summer—and this plan he continued to follow about eight years, and would have continued it longer but for the inconvenience arising from the want of *pasture*. It is to be regretted that he did not keep an exact record of all his crops: however, he assures me that the following may be depended on as very near the truth. His first crop of corn was eighty-five barrels, his second thirty-five, of which twenty were short corn. (It may be well to mention that a barrel of corn is five bushels of *grain*, or ten bushels of *ears*.) His second crop of wheat was two hundred and fifty bushels from 45 of seed, being five and a half for one. His third crop of 350, nearly eight for one. Fourth 500, fifth 700—and so on, increasing every year, until, in the year 1816, having altered the arrangement of his fields from two of forty-five to three of thirty acres each, he reaped from sixty-seven and a half of seed a thousand bushels of prime wheat,—one half on corn land—the other fallow. This crop he had the good fortune to sell at two dollars 91 cents per bushel, and the good sense, although not pressed, to apply the proceeds to the payment of debts necessarily contracted in the erection of buildings, among others an excellent barn, and the purchase of three or four boys; and various expenses incident to a new establishment and growing family. It should be remarked also, that, until the end of the year 1818, his land was burdened with a third of the estimated rent, as dower.

No memorandum can be found of his crops for the three succeeding years, nor does he recollect the amount; but they were not so great as that just stated. He failed in one crop from defective seed which he purchased.

In 1820 he reaped eleven hundred and twenty-seven bushels from ninety of seed, thirty of which was sown on the out-field before mentioned. This, and several other crops to be noticed, he has on record. In 1823 his wheat crop from seventy-two was one thousand and thirty-nine bushels—nearly fourteen and a half for one.

In 1830, from 88 of seed he reaped fourteen hundred and ninety-seven bushels of wheat, 17 for one—one half from corn-land, the other fallow—thirty acres each—the fallow yielded *twenty-five for one*—see some account of this crop in the Farmer about July 1830.

Last year, being much occupied in repairing and building, he seeded only fifty bushels of wheat, which produced a crop of six hundred and twenty-eight bushels. All this was on corn-land except a lot of five acres, which, from seven and a half of seed, gave one hundred and fifty-seven bushels, nearly *twenty-one for one*. I have confined myself principally to an account of his wheat crops, because he could not inform me with so much accuracy the amount of his corn crops—they were generally good, seldom fallowing below three barrels to the thousand and frequently reaching four. His greatest crop of corn was in 1827, from two of his thirty acre fields, five hundred and twenty barrels.

Last year he bought five thousand bushels of oyster shells, at the cost of one hundred dollars—burnt and spread them as far as they went, at the rate of 200 bushels per acre just before planting corn, on the out-field, which got also a dressing of farm-yard manure. The crop of corn, just gathered, is fair—few in the county better.

His shell-banks giving out and the drifts of sea-ware being less abundant than formerly; about eight years ago he commenced the use of marsh, and heads of creeks, of which he thinks favorably, paying strict attention, as usual, to the farm-yard and compost heaps. He has one now, containing upwards of a thousand *skates* or double-heads, taken a few weeks ago in his seine—from this he calculates on a thousand cart loads of manure for his corn-land next spring. From their livers he extracted seventy-three gallons of oil. From experiments made last year with similar oil, he is of opinion that it is a remedy against the worm, so destructive to the peach tree. He does not spread sea-ware so thick as I recommended in my last, on account of the difficulty of ploughing in—nor would he recommend the shells to be put so near—intervals of five lands should be left: between marsh, &c. three. I readily yield to his superior judgment.

For fourteen or fifteen years past he has made great use of the sickle—much of his wheat being too rank for the cradle. He ploughs about four inches deep, and cannot be induced to go deeper—in good land sows a bushel and a half to the acre, in poor one bushel; breaks his fallow ground about the middle of June—cross ploughs soon after harvest—rolls and harrows—and, if likely to be grassy, gives it a third ploughing—puts in with the plough, very shoal, in narrow ridges, keeping his manure near the surface. I consulted him respecting the question of Potomac: he is of opinion that no danger is to be apprehended from the application of rotten marsh to growing crops, if put on in reasonable quantities.

It will be observed that this farm, notwithstanding its rapid improvement, has been *severely cropped*,—present gain, from necessity, being the main object. The proprietor was not insensible of the value of clover as an improving crop; but he could not let it remain long enough to be of much use to the land. He never cut but one field crop of it, 1825, upwards of fifty tons from thirty acres. Hereafter, having got his out-field in pretty good order, he will adopt the four-field system, cutting one field of clover every year. His regular force is five able hands, with some small boys,—he runs three ox and two horse-carts—has never kept an overseer, and for many years labored daily. I have not thought it necessary to state his root crops—the produce of his hog-pen, &c., supposing that his principal crops would clearly show the progress of improvement.

There are three other farms within a few miles of Emerson's Point, on which wonderful improvements have lately been made. I mean those of Colonel John Tilghman, Mr. Edward N. Hambleton, and of Doctor John Barnett. I hope they will favor the public, through the columns of your useful paper, with an account of their management, crops, &c. There are other farms in the same neighborhood which deserve honorable notice and minute description; in particular, those of Mr. Rigby Hopkins, Major Wm. Caulk, Mr. Joseph Harrison, and Mr. Stephen Harrison, improved, principally, by the use of *shell-lime*.

CORNPLANTER.

From the Lexington Gazette.

AGRICULTURAL SHOW AND FAIR OF THE AGRICULTURAL SOCIETY OF ROCKBRIDGE.

October 11*th*, 1838.

The society upon being called to order, by the president,—Professor GEO. D. ARMSRONG, of Washington College, delivered the annual address.

The premiums were awarded as follows:

For the best stud colt under 4 and over 2 years old, to Jno. McKamy of Augusta.

For the best brood mare, to James Johnson.

For the best filly, to Saml. McD. Reid.

For the best bull, to A. T. Barclay.

For the best milch cow, to William Moffat.

For the best heifer, to Thos. Wilson.

For the best bull calf, to Thomas Wilson.

For the best boar—A premium was awarded to two of equal merit, viz.: to Thomas Wilson and A. T. Barclay.

For the two best rams, to Jno. Jordan and A. T. Barclay.

For the two best ewes, to Jno. Jordan and A. T. Barclay.

For the handsomest and best counterpane, to Mrs. R. Grigsby.

For the best piece of sheeting, to Miss Johnston.

For the best piece of table linen, to Miss E. Finley.

For the best pair of blankets, to Mrs. Jno. Jordan.

For the best man's saddle, to Jno. T. Figgat.

For the best specimen of ploughing, to Wm. Moffett.

The committee recommend to the directors, to award premiums for counterpanes to Miss Grigsby and Miss Finley—for hearth-rug, to Miss Christian—for a piece of flannel, to Miss Alexander—for a cheese, to Miss Grigsby.

On motion of Samuel McD. Reid, it was resolved, That hereafter, no premium will be awarded to any person who shall not have been a member of society more than six months previous to the awarding of such premium.

On motion of C. P. Dorman, it was resolved, That the president and directors of the Rockbridge Agricultural Society, prepare, and address a memorial, to the general assembly of Virginia, on behalf of this society, asking its incorporation, and praying the aid of the state to the cause of agriculture, and agricultural societies.

On motion of John F. Caruthers, it was resolved that the corresponding secretary communicate the foregoing resolution, to the several agricultural societies of Virginia, and solicit their immediate and active co-operation.

On motion of C. P. Dorman, it was unanimously resolved, That the thanks of this society are due to Professor GEO. D. ARMSTRONG, for the able and appropriate address this day delivered by him, and that a committee be appointed to communicate our sense of its merit, with a request that a copy be furnished for publication.

Committee appointed by the president under the foregoing resolution—C. P. Dorman and A. T. Barclay.

The society then proceeded to the election of officers for the ensuing year, when

Maj. John Alexander was elected president.
Thos. Wilson, vice president.
J. T. L. Preston, corresponding secretary.
A. T. Barclay, recording sec'ry.
Henry B. Jones, Matthew White, & Robt. McCluer, } *Treasurers.*

And Jos. Cloyd, Wm. Moffir, R. R. Barton, Alfred Leyburn, Saml. McD. Reid, Jno. F. Caruthers, C. P. Dorman, Saml. Wilson, Jonathan Brooks, Wm. Houston, and Wm. Inglis, *Directors.*

Resolved, That the next annual meeting of this society be held on the 3d Thursday of October next, at Fancy Hill.

Adjourned,
SAML. WILLSON, Pres't.

Teste,
A. T. BARCLAY, Sec'ry.

From the Salem Observer.

THE SNOW OWL.

Taking a stroll among the market wagons that crowded our streets, on Wednesday, laden with poultry and other agricultural products, we noticed in one of them, a living specimen of the snow owl, which was captured in Topsfield. Every season, between the months of November and February, several of these beautiful birds are seen hovering around—always exciting a considerable degree of interest; their movements are generally so closely watched, that not a few of them are taken by the lovers of the chase and others.

They are inhabitants of the coldest and most dreary regions in the northern hemisphere, being constantly found in Iceland, Norway, Lapland, and the country adjoining Hudson's Bay. In the Atlantic states they are merely a winter visiter, and in their migrations wander along the sea coast as far as Florida, sometimes stretching interiorly, as they are met with in Ohio and Tennessee, and have been seen in the vicinity of the Red and Arkansas rivers. In Massachusetts and Maine they are more abundant than in any other part of the United States.

To protect this bird from the external cold to which it is exposed, especially in its native haunts, nature has bountifully provided it with a complete encasement of the most soft, warm, and elastic plumage beneath the outer covering of feathers, and so closely matted together that it is difficult to penetrate to the skin.

Its short and curved bill is nearly hid by the mass of feathers that cover the face; the feet are covered with a long, thick hair-like plumage, resembling very much those of a dog, the claws, which are curved, black and sharp, only being visible; the eyes are deep sunk under projecting eye-brows; and are of a bright yellow color; the general color of the body is white, and usually more or less marked with spots of pale brown, according to the age or sex of the individual.

AN ALLIGATOR IN NEW YORK.

The New York Sun says that a stonecutter employed in a shantee near the corner of Seventh street and avenue C, was on Thursday breaking the ice in a pond in a vacant lot in that neighborhood, when he was suddenly and not very agreeably surprised. No sooner had he made a hole than out jumped *a large alligator!* He raised an alarm and the animal was forthwith attacked and despatched without mercy. He measured from head to tail seven feet ten inches. The Sun says that one of these animals was picked up in the East river last July. But how they came there, or for what purpose, no one can tell.

From the Journal of the Franklin Institute.

ON THE PART WHICH THE SOIL ACTS IN THE PROCESS OF VEGETATION. MEMOIR READ AT THE ACADEMY OF SCIENCES, BY J. PELLETIER.

Translated from the Journal de Pharmacie, for the Journal of the Franklin Institute, by J. Griscom.

The ground is the support and nurse of plants; in its bosom, by means of roots, they seek for and find a portion of their nourishment. But to this truth, so simple and obvious, are attached questions of a complicated nature, and of the highest interest to physiology and agriculture. With one, among others, I have been particularly arrested, and it has been the object of my meditations. Before I enter upon it, permit me to bring into view some facts which appear to be necessary to the discussion of it.

The earth is not an elementary substance. Its exterior bed, the residence of plants, is formed of various metallic oxides, silica, alumina, lime, to which are often joined magnesia and the oxide of iron. It contains, moreover, the detritus of organic matters which had before possessed life and existence. Thus constituted, and under the influence of air, water and imponderable fluids, the earth is eminently fit for the development of germs deposited in its bosom, and to the growth of the vegetables which flourish upon it.

The necessity of the presence of organic matter, to constitute a soil, endowed in the highest degree with vegetative force, cannot be considered doubtful. In vain did Tull, in 1773, attempt to maintain that distinct earthy particles formed the sole nourishment of the plant. This theory was overturned by the positive experiments of Duhamel who had at first embraced it. Nevertheless, if it is certain that the presence of organic matter is a condition of fertility, we may still ask whether it is so *essential* a condition—such a *sine qua non*,—that a plant cannot vegetate in a soil totally deprived of organic matter, particulary if other circumstances, such as the presence of water and carbonic acid, be united with it.

Numerous experiments have been made to resolve this question. Many of them are contradictory. The greater portion, from the high interest which they involve, ought to be discussed and repeated with care. But another question not less important, and which I think ought to be first ascertained, is this: *What influence have soils themselves in the act of vegetation?* To this question I at present confine myself.

A vegetable soil, in its normal state, must be considered a mixture of various earths, that is, of metallic oxides.

Every soil devoted to agriculture, is in general, says Chaptal, formed of a mixture of silica, lime and alumina, and in support of this assertion he cites various analyses.*

Davy confirms this statement in his Agricultural Chemistry, and, in fact, not a single instance of a fertile soil has occurred, which consisted of only one earth, or even of two, such as lime and silex, silex and alumina, alumina and lime.

In another passage in his *Chimie Agricole*, Chaptal expresses himself thus:

"A mixture of lime, silex and alumina forms the basis of a good soil; but that it may possess all the desirable qualities of good land, these ingredients must exist in certain proportions, which analyses of the best soil can only establish.

If we consult the analysis of the most fertile soils, we find that fertility diminishes in proportion to the predominance of either of these principal earths, and that it becomes almost null when the mixture has the properties of only one of them."

Complexity of composition is therefore, in general, a condition of fertility in a vegetable soil. The loose earth which we find in valleys arising from the decomposition of primitive rocks, makes generally an excellent soil. Now we know that granite, composed of quartz, feldspar and mica, and frequently amphibole, must yield by its composition, a soil containing silica, lime, alumina and a little magnesia and sometimes potash. Soils originating, on the contrary, from the decomposition of more simple rocks, siliceous limestone, for example, are lighter, and suitable only for a limited number of plants; they require, says Chaptal, to

---

* A very fertile soil in Sweden was found by Bergman to consist of:

Coarse Silex,	30	56
Silica,	26	
Alumina,		14
Carbonate of Lime,		30
		100

A fertile soil in Middlesex gave Davy—Siliceous Sand 3-5; the remaining 2-5 consisted of

Carbonate of Lime,	28
Silica,	32
Alumina,	39

Analysis of a fertile soil in Touraine:

Sand,	49
Silica,	16
Alumina,	10
Carbonate of Lime,	25
	100

A very fertile compost, formed by Tillet consisted of clay 3-8, pulverised lime-stone 3-8, sand 2-8, corresponding to

Course Silex,	25
Silica,	21
Alumina,	16.50
Carbonate of Lime,	37.50
	100

be enriched, and are valuable only in moist climates. Land originating in the decomposition of trap, basalt and other rocks of complicated elements, possess, on the contrary, great natural fertility.

"Rivers," he further adds, "receive in their courses other streams whose mud is mingled with its own, and it often happens that the united sediment of two rivers possesses greater fertility than that of either separately."

This then appears to be an established fact, that a soil (independently of organic matter) is the more fertile as its composition is more heterogeneous.

If we seek for an explanation of this fact, we find in authors only vague opinions and doubts; the greater number merely state the facts without attempting an explanation.

Agricultural chemists, who indulge more in theory, appear to regard the cause of fertility as dependent on the physical character of the soil rather than on its chemical constitution. Thus Davy having observed that different soils attract moisture with different degrees of energy, and having discovered, as he believed, that the most hygrometric soils were the most fertile, he ascribes their superior fertility chiefly to this property. But Davy has not proved that the hygrometric force of a soil bears any given relation to its composition.

If this attraction of moisture were the principal cause of fertility (abating the influence of manures) we perceive no necessity for the combination of the three earths in the constitution of a soil of the first quality. Indeed a certain quantity of alumina in a soil otherwise entirely siliceous, or entirely calcareous, a certain proportion between the adhesive and the loose or sandy portions, would be sufficient to confer this hygroscopic quality, and of course the fertility of the soil. But we have nothing to confirm this supposition.

The hygroscopic quality of a ternary soil may then be considered as an *element* of fertility, but only a secondary element, subordinate to its chemical composition.

The property of becoming more or less heated by the rays of the sun, which appeared to Davy to hold a relation to the fertility of different soils, appears to me to be also a secondary cause. In the cases referred to by him there was a mixture of black mould, and he did not sufficiently consider its fertilizing action as a manure upon the soil.

To me, it appears evident, that the mixture of the various earths which compose a soil, acts upon vegetation and determines its fertility *by an electro-chemical force*, whose action has been clearly recognized in other circumstances, but not yet brought into view in the case now under consideration. In the first place, let us observe, that it is a fact, though the truth may have escaped observers, or rather, it has not yet been brought under a formula, that the silica, alumina and lime which enter into a good vegetable soil, must not be combined with each other, but simply mixed, the lime being in the state of a carbonate. A triple silicate of lime or alumina, in which the silex, lime and alumina should be in the proportions which constitute the best arable land, could not, even if thoroughly divided, furnish a soil essentially adapted to vegetation. If, in a fertile soil, composed of a mixture of lime, alumina and silica, a combination between these three oxides should begin to take place, the ground would become cold and steril. Now, it is certain, that in a mixture of these three ingredients, a force does exist which tends to combine them. The silica and alumina are, in relation to the lime, electro-negative bodies, and in their presence the lime must acquire a contrary electricity. According as external or mechanical movements of the soil, or other foreign causes, shall bring these molecules within greater or less distances from each other, and group them in various ways, electrical piles will be established, discharges will take place, producing various tensions, and the earth will thus, if we may use the term, become animated. The electric fluid which pervades it will excite the stomata of the radical fibrils, determine the play of the organs, and the absorption of the fluids requisite to the nourishment of the plant. The radical fibrils, and the capillary roots impregnated with moisture, will become so many electrical conductors, engaged in transmitting electricity, certainly as necessary to life as light and caloric.

The merit of a theory is, that it accounts for observed facts, enables us to foresee what will take place under particular circumstances likely to happen, and indicates the considerations which it may be desirable to bring about with a view to useful results.

Let us inquire whether the theory now presented, fulfils these conditions:

Suppose a chalky soil. To improve it, we add argillaceous marl; i. e. to the lime which predominates we add silica and alumina. *To the positive element which we found alone, we add the negative elements which we found deficient.*

Will it here be said, that "chalk is so compact that the roots cannot penetrate it, or so split up that water passes through it like a riddle, and that the marling is simply designed to change this physical condition?*

But, if the object was merely to divide the chalk, in order to change its physical condition, a calcareous sand would accomplish this object, and yet it never came into the head of an agriculturist to improve his chalk by limestone, while Gordan de Saint-Memin produced a magnificent vegetation by a mixture of chalk with heath sand.

In a piece of ground belonging to Chaptal, the soil was clayey and rather barren; below was a layer of black earth. Chaptal went to work empirically, dug up the ground and mixed the two beds together. Contrary to his expectations, the sterility was increased. It was not till the fifth year that the ground acquired a common degree of fertility, that is, when all the iron had passed to the state of peroxide, and the land, black as it was, had become of a deep, bright yellow. Chaptal asks, if, in this case, the black oxide is injurious to vegetation, either by itself, or in reference to the oxygen.

In our theory, the fact explains itself, and might have been foreseen: the black oxides of iron (fer oxidule d' Haüy) is a combination of protoxide and sesquioxide of iron, a substance *indifferent* in relation to silica and alumina. Exposed to the air, the combination is destroyed, the iron passes to the state of peroxide, susceptible of union with silica and alumina. Yet, under such circumstances, it was not worth while to mingle the two

* G. Dict. d'Agriculture, article *Craie*.

beds, since five years were lost in attaining a common degree of fertility.

The theory which we have adopted, is applicable, likewise, in the happiest manner, to the operation called marling. Marl is not a simple mixture of silica and alumina with more or less of carbonate of lime. Its base is argillaceous and calcareous silicates; some mineralogists consider it even as an oryctognosaical species.* It is on this account that plants cannot vegetate in marl which has been long exposed to the air, even when the silica, alumina and lime are in the proportions which form good arable land. By exposure to the air, carbonic acid *destroys the combination* which existed between the earths, and it is then, and then only, that marl will enrich the soil. In this case, if the negative element prevails, as in the case of argillaceous marls, it becomes excellent for calcareous soils; and marls called calcareous are in their turn advantageous for argillo-sandy land.

It has been remarked, that the alkaline and earthy salts, which, in a certain quantity, injure vegetation, produce a good effect when employed in small doses. Chemists and farmers have sought to explain this action of saline compounds. Some have thought that certain salts were good for plants, as some are for animals—that salts, and even earths, formed part of the food of vegetables; others, on the contrary, that they act principally as stimulants to vegetation. Without denying that earthy substances may enter into the constitution of a vegetable, to unite and give strength to the parts that are to support the organs, like phosphate of lime in the bones of quadrupeds, I may remark, that with a few exceptions, the presence of any salt is not absolutely necessary to vegetation. Thus, for example, borage and lettuce, whose extracts contain much nitre when they grow in highly manured soils, do not contain any sensible portion of it when cultivated without dung. I therefore rather incline to the opinion of physiologists, who think with M. Decandolle, that salts act as excitants or stimulants. But, what is the meaning of excitation? At the present day, science no longer admits of those vague explanations which consist of nothing but words. I understand by excitation, the eminent property of conducting electricity which salts communicate to water. It is in this manner, as it appears to me, that nitrate of potash acts, in the prodigious energy which it gives to vegetation. It is probably in this way that sulphate of lime acts; that is to say, by rendering the water a better conductor, though, in this case, the effects appear to me to be complicated, and to be worthy of direct experiment.

Thus far, for greater simplicity, we have considered lime as free, in speaking of the mixture of silica, alumina, and lime, which constitute a soil: now the lime is in the state of carbonate, but it does not, in that state, cease to be an electro-positive element in relation to silica and alumina. This circumstance allows us to explain an important vegeto-physiological fact. The carbon in vegetables is produced mostly, if not entirely, by the decomposition of the carbonic acid which they absorb not only from the air, but from the ground: such is the opinion of the celebrated Decandolle. This carbonic acid, furnished by the ground, appears to enter into the vegetable at the moment of its liberation, probably dissolved in the water which the soil contains. It is absorbed by the spongioles of the radicules; it ascends with the sap, urged forward as by a *vis à tergo*. But how is this carbonic acid produced? In certain manured soils, and in superficial portions of the earth, penetrated by the air, we may conceive it to be formed by the re-action of oxygen upon the carbon of organic detritus; but at those great depths which are attained by the roots of oaks and cedars of a hundred years old, how can the carbonic acid be developed? How can the oxygen and organic matter penetrate to such depths? In our theory there is no difficulty. Carbonic acid comes from the lime, on which the silica and alumina act slowly but continuously to form silicates.*

Thus, then, at certain depths, and under influences but little understood, silica would decompose carbonate of lime, while at the surface of the earth, and under the influence of exterior agents, the silicates would be decomposed by carbonic acid produced by the reaction of the oxygen of the air on organic detritus—an admirable and providential rotation, which re-establishes the equilibrium, and incessantly tends to the rejuvenescence of nature.

The last corollary of my theory—the decomposition of silicates by exterior agents, and particularly by carbonic acid, cannot be called in question. It has been established by M. Becquerel, under circumstances in which the force of cohesion might seem to present a serious obstacle. I allude to the decomposition of the feldspar of granite, and the formation of kaolin. The analogy is here so strong that I must render the homage of my first conception to the distinguished academician I have just cited.

The fact of the decomposition of carbonate of lime by silica in the interior of the earth is equally supported by experiment and observation. And, first, if, in proceeding to the analysis of a vegetable soil, when the coarser siliceous sand has been separated by agitation and deposition, and the carbonate of lime has been removed by weak acids, we examine the finer terrene substance which has resisted the weak acids, we find that it is not alumina, as Chaptal indicates, nor silica, as is stated in various works, but that it consists principally of veritable silicates of lime, of alumina, and of oxide of iron.

Still, it may be objected that these silicates are anterior to all vegetation; that to prove their recent formation and daily production, requires direct experiments. These direct experiments are among the objects which I wish to undertake. They require much time. But to prove truth, are we to depend solely upon new experiments

* Brochant's Mineralogy.

* Animal manures may contribute to the decomposition of silicates, not only by the carbonic acid which they form by absorbing oxygen from the air, but in producing such substances as the FAT ACIDS, which have a tendency to unite with lime and to eliminate the silica which is combined with it. M. Raspail, whose talents we are glad to acknowledge, without sharing in all his scientific opinions, appears to us to have explained the siliceous petrefactions that are found in chalk, in a very happy manner by the action of animals entombed in siliceo-calcareous beds.

[*Physiol. Vegetale*, t. 2. p. 339.

peculiar to him who advocates it, and are we forbidden to rely on the labors of our predecessors? Certainly not. I may therefore again refer to the interesting researches of M. Becquerel, and bring into view those mineral species which he has formed in his laboratory, and which present all the characters of their natural congeners. Neither can I omit to mention the important fact of the artificial formation of feldspar by Cagnard de Latour.

There is still another objection which may be made to the theory now presented. If, in this mixed state, the earth acts by virtue of electro-chemical forces, why are three earths requisite to the construction of a good soil? Ought not silica and lime, or lime and alumina to be sufficient to produce, in each element of the mixture, an opposite electricity? It is easy to answer this objection also, by a reliance upon facts well known to mineralogists: it is certain that the binary silicates are more rare in nature than the ternary silicates, and that their mass in particular is less powerful: silica has therefore a greater tendency to combine with lime and alumina together than with either of these earths separately. Hence, we may perceive, that the union of the three becomes necessary to constitute a soil endowed with the highest degree of vegetative power.

If the ideas which I now submit to the academy appear to deserve any attention, I propose, on the return of the favorable season, to renew the inquiry, and to devote myself to the labor of positive experiment—experiments, which, whatever may be their results in reference to my theory, will at least have the advantage of eliciting facts which may be friendly to agricultute, that science which is so prominently stamped with the character of utility.

THE SYSTEM OF PLUNDER PRODUCED BY THE SYSTEM OF IRRESPONSIBLE BANKING.

[The following letter, by Dr. Hagan, editor of the Vicksburg Sentinel, and a bank commissioner, presents a picture of effects which have not yet been produced so completely in any state except Mississippi, but which may be produced any where by the same cause, viz.: banking corporations not being held strictly responsible for all violations of their legal and moral obligations. And whatever may be the letter of the law for restraining bank frauds, the restrictions and penalties imposed are in fact made null and void, by the state and the bank being in any manner partners in trade. The partnership, and (supposed but not real) identity of pecuniary interest of bank and state, (for the state partner is sure to be the loser,) is the great evil of the system in Virginia. If banks were permitted to trade only on their own capital and credit, and without having the government for a partner and supporter, then there would be much less danger than now threatens, even if in that case they were to push their operations to the utmost wants of the trade, and judicious enterprise, of the country. Make them as much responsible for over-trading, and for incurring obligations which they cannot perform, as are all other corporations, and all individuals, and there would be no greater danger of their running into excess. But who is it, whether a private or corporate trader, who will not, for the sake of greater gain, incur obligations which cannot be redeemed, when knowing that so soon as the penalty is about to be incurred, the government, the strong partner in the firm, will step in to ward off the threatened blow, and annul the penalties incurred, and about to be incurred?—ED. FAR. REG.]

From the Mississippi Intelligencer.

We feel it to be a sacred duty that we owe to the cause of justice, to warn the public against the infamous schemes which are now being concocted for the unholy purpose of robbing the community of their honest earnings. Every hobby, from the theory of the alchymists to the charms of animal magnetism, has had its day of triumph; but the present seems to be the age and the supremacy of swindling in Mississippi. Unless the people arouse from their lethargy and put down the nefarious band of robbers who are now maturing the most extensive system of speculation and fraud that ever disgraced a civilized country, the character and the prosperity of the state will receive a fatal blow. A high-handed system of plunder has been carried on by most of the banks in this state for the last twelve months. The people begin to feel and understand the effects of this system; but they have no idea of the deep and damning conspiracy by which the swindlers contemplate the plunder of the community. We had but an imperfect idea of the extent and the enormity of the swindling and corruption of most of the banks in this state. The chartered, and real estate or unchartered joint stock companies for the issue of paper money, seem to vie with each other for supremacy in the base art of swindling the people out of their property; and we now call on the public, as they regard their own interests and the prosperity and honor of their country, to be on their guard. The banks swindled them out of the principal part of last year's crop, and they are bent on getting possession of the present. The people were deceived by the falsehood and knavery of the banks last year; but it will be their own fault if they permit the banks to rob them of this crop after this warning and past experience. The northern counties of the state are more cursed with banks than even the southern counties; they are springing up three or four in almost every county, and in many instances the unchartered or real estate banks seem to be more infamous than those that swindle under the *forms* of law. But it seems that this state is not sufficiently extensive for these plunders; and they have extented their operations to Texas. We have been credibly informed that the "Oakland Bank," "one of the machines for making money," has despatched a pair of saddle-bags full of their notes to Texas, in order to obtain the property of the people of that country for their worthless trash. It is said that the joint stock company of this county has passed off in Texas fifty thousand dollars of their paper, which is probably not worth more than a dollar a bushel. We know that it will not now pass in the very town in which it is issued, though travellers have it imposed upon them at a distance of hundreds of miles. Banks whose charters required the stock to be paid in "in specie or the notes of specie paying banks" have been organized without a single dollar of either having been "paid in," and now these same banks are issuing and flooding the country with thousands and tens of thousands of their notes. These notes are put in the hands of agents in every part of the country in order to be advanced on the present crop of cotton; and each agent exercises banking privileges! It is in this way that the banks intend to rob the country of the proceeds of its industry. They hold out the impression that as soon as they send the cotton to market they will redeem their notes with the good money which cotton will always command; but as soon as they get possession of valuable property for their false promises to pay, they laugh at their note-holders, and use the funds with which they ought to redeem their promises, in speculations in pork, bagging and bale rope, and in purchasing up their own or their neighbor's paper at 30 or 40 per cent. discount, or the lowest price for which it can be obtained in market, and the pork, &c., is again sold to the people at two prices.

Every class of men who can exercise an influence in pursuading the honest and unsuspecting planter to exchange his cotton for this irredeemable and worthless trash, will be sought by the banks to be enlisted in this unrighteous and unholy operation. Influential men of all parties are engaged in it. Whigs, Democrats, and we are sorry to say, even Nullifiers, from whom we would expect better things, are found playing this swindling game. Every sense of justice and lofty moral feeling seems to wither and die at the approach of this odious and avaricious spirit of banking. Members of the legislature, members of the church and ministers of the gospel may be found embarked in this infamous speculation. The saddle-bags full of "Oakland" notes, (already alluded to,) which are probably not worth more than as many oak leaves, have been entrusted to a distinguished reverend gentleman to be circulated in Texas. By prayer and the assumption of piety he will more effectually succeed in disarming suspicion and in imposing on the people. He will, unless this notice arrests his swindling career, soon obtain leagues of Texas land for the contents of his saddle-bags. Men who have heretofore borne good characters, and who would scorn to pick pockets or steal a dollar from their neighbor, have now no hesitation in swindling to the amount of thousands. What is the difference between picking a man's pocket of 50 dollars, and the directory of a bank conspiring together to render 1000 dollars of their issues worth only 500 dollars. If ten mechanics receive each one dollar of this money for their labor, or ten merchants the same for their goods, each of the ten directors might as well filch fifty dollars from the pocket of one of these note-holders. The moral turpitude is the same. The very men engaged in this business will acknowledge its impropriety; but justify themselves by saying others are engaged in it, and we must in self-defence take a hand in the game. If we do not we will suffer the loss without receiving any of the profits. Now if the whole world could live in prosperity and happiness, by swindling, this might be a very good argument. But the very idea is repugnant to every principle of common sense or common justice, without which the elements of society cannot cohere.

The notes of one of these establishments will not pass 11 miles from the place of issue unless at enormous discount. In paying for our dinner a short distance from Holly Springs, we had our choice to pay 50 cents in irredeemable shin-plasters issued hundreds of miles off, or 75 cents in McEwen, King & Co.'s notes! Those who issued this paper might with as much justice have stolen my property to the amount of one-third of their notes which I spent after taking them in payment of debt; and yet it is said that this institution intends to throw out two or three hundred thousand dollars more of its paper and exchange it for cotton!

Now as it is impossible for a cheap or spurious currency, and a sound one to circulate together, the above evils will curse the country, until public indignation shall have banished them from circulation, or until the laws of the country shall have provided apartments in the penitentiary for all men engaged in this nefarious swindling. As the latter is necessarily a work of time, we now call upon the people to adopt the former. Every honest man is interested in putting down this system of robbery. Let the honest merchant, mechanic, planter, and professional man meet and declare unanimously not to receive any of these false promises to pay either in payment of debt, or for cotton, or for merchandise. Now is the time to destroy these worse than Egyptian plagues. Let the planters refuse to take their paper in payment for cotton. If they are indebted to the banks, let them sell their cotton for good money, and purchase up the trash to pay the bank debts. This will be an effectual mode of disinfecting the country, and eradicating one of the most loathsome diseases that ever afflicted a people not under the special vengeance of the Deity. If the people do not pursue this plan, but place their cotton again in the hands of the swindlers, they may prepare to pay 40 or 50 dollars a barrel for pork next year. Their currency will also be worth about 50 cents in the dollar, and the banks will reap another glorious harvest, buying up bank notes, extorting from the planters and mechanics about three prices for provisions, bagging, bale rope, &c., and finally they will destroy the whole planting and mercantile interests of this country. The honest portion of the community is called on by every consideration of justice, of patriotism, of self-respect and self-defence, to consult together and unite in one solid phalanx to resist the desolating march of these bold and daring swindlers.

Some of the banks will resort to every trick and device to deceive the people this year and to get the control of the present crop of cotton. They took the lion's share of the last crop, and it will require some ingenuity to cheat the planter again. Last year they held out the idea that they would check on the north in a few weeks and make their paper good; this year they will be compelled to raise the value of their paper, which they will do about the commencement of the season. They will then induce the belief that they intend to resume specie payments every month. But let the people have nothing to do with their paper or their promises till they commence paying specie. They were deceived last year; this was the fault of the banks; if they are plundered this year, the fault will be their own. When the report of the bank commissioners shall appear, the oldest swindlers will be astounded at the scenes of speculation, corruption and fraud which modern banking has given rise to in this state.

JAMES HAGAN.

From the Farmers' Cabinet.

STATEMENT OF THE CULTURE AND PRODUCTS OF A LOT, THROUGH A SERIES OF YEARS.

Catawissa, Columbia county, Pa., Oct'r. 11, 1838.

Dear Sir—Knowing the deep interest that you have taken in the promotion of agriculture, and possessing something of the same spirit, induces me to communicate to you the manner that I have pursued in farming a lot, containing three acres and three quarters, adjoining our town. I have also farmed 130 or 140 acres to very good effect, a part of which has produced quite equal to the lot above mentioned. The lot is on the second rise from the river Susquehanna, and was formerly covered with yellow pine saplings—the soil is rather light—I purchased it 14 or 15 years since. I farmed it for seven or eight years with wheat and clover alternately, mowing the first crop of clover and ploughing down the second, and sowing wheat after one ploughing, and harrowing it in. I have had 40 bushels of clean wheat to the acre in this way of farming, and found my land to improve. In the autumn of 1833, I sowed timothy seed shortly after my wheat, and in the spring following clover seed also, and had a good crop of wheat in 1834.

In July 1835 I cut $16\frac{1}{2}$ tons of excellent timothy and clover hay from this piece of land, say worth $12 per ton, amounting to	$198 00
July 1836 cut $14\frac{1}{2}$ tons of hay at $12	174 00
July 1837 cut $15\frac{1}{2}$ tons of hay at $12	186 00
Oct. 1838 had 636 bushels of corn in the ear from $3\frac{1}{2}$ acres of it, say 318 bushels of corn at 75c. per b.	238 50
Oct. 1838 had from $\frac{1}{4}$ of an acre of headlands of lot, 30 bushels of potatoes at 75 cts. per bushel	22 50
Oct. 1838 had 200 pumpkins grown among corn at 1 ct. each	2 00
Prod. of $3\frac{3}{4}$ acres for 4 successive years	$821 00

In the statement of the corn I have not included 10 or 12 bushels of ears, sold or taken from the lot for boiling. The crop is rather extraordinary for the season. Last fall I ploughed down the sod that had been mowed for the three previous years, which sod had been well manured the spring before—early this spring it was well harrowed, and at planting time it was furrowed out three feet apart each way, and four grains put in each hill, and two rows of potatoes planted around the lot. The cultivator was principally used in dressing the corn, and at the last dressing, one half the lot was reduced to two stalks to the hill, leaving three stalks in the other half, and taking care to let the thriftiest plants remain. In furrowing out, care was taken not to turn up the sod.

On examination of the ears, it was found that where there were three plants to a hill they were more numerous, but where there were two only, the ears appeared to be larger. It was the large yellow corn that was grown, and some of the ears were eight inches in circumference, and many of them from 13 to $14\frac{1}{2}$ inches in length. The seed was taken from stalks that had two or three ears on each, taking the upper and the best one. The lot has been sown with wheat since the corn was taken off; it had been topped, and as the ploughing progressed, a man and boy pulled up the stalks and placed them in the furrows, with the but or root end towards the plough, and in this way the whole of them are completely buried, and if I mistake not, will decompose and make a good manure. The ploughing turned up the old sod which had not been disturbed during the season, and it presents at this time on the surface the appearance of a rich coat of manure, and I would not exchange the chance for wheat from this piece for that of any other of the same size—if I live till next harvest I will let you know the result.

I think there is an average crop of corn in the valley of the Susquehanna, from this to Wilksbarre, say 45 miles. The crop of hay never was exceeded; wheat excellent; rye and oats rather light, buckwheat very light, having been destroyed in most instances by the frost in the early part of September.

Respectfully, your friend,
JOSEPH PAXTON.

From the Library of Useful Knowledge.

FLEMISH HUSBANDRY.

Of the Cultivation of Roots, Potatoes, Turnips, Beets, Carrots, Parsnips, Chicory.

If we are indebted to the Flemish for the introduction of clover and turnips into our agriculture, they are equally so to us for the valuable potato. This root is now become a great substitute for corn throughout all Europe, and its influence on the population cannot be denied; when corn fails potatoes are generally most abundant, and thus prevent that distress, which is so great a check to population. In Flanders potatoes form a part of every rotation, the light soils being peculiarly adapted to the growth of this root; and as a great part of the produce is consumed by cattle, and thus gives an adequate return in manure, the objection often made to its extensive cultivation, that it exhausts the soil and returns little to it, is not well founded. Where it not for potatoes to keep the cattle during the latter part of the winter and beginning of spring, when the supply of turnips fails, a much smaller number could be kept; for hay is a dear fodder in most parts of Flanders.

Potatoes were at first only known as an esculent root in gardens; and it was a long time before their real value was found out. In 1740 they were for the first time sold in the market of Bruges, in consequence of the zeal of an individual of that town, Mr. Verhulst, who distributed some sets gratuitously to the farmers in the neighborhood. From that time the cultivation increased rapidly, and spread all over the country. The varieties which are mostly sold in the towns are the earliest and best flavored, which are chiefly raised in sheltered gardens. The plant being a native of a warmer climate cannot bear the least frost. It is therefore not safe to plant it in the fields before March or April. The sets which are planted to produce an increase, are not seeds but buds, and as such perpetuate the qualities, good or bad, of the parent stock. Each variety proceeds from some original plant raised from seed, and is subject to age and decay with its parent. Hence varieties continually degenerate or wear out, and fresh or new varieties must be produced by sowing the seeds; recent experiments and observations fully bear out the truth of this assertion. It is therefore not sufficient merely to find a superior variety, the age of the parent plant should also be noted. Some will last longer than others, but all old varieties sooner or later show marks of decay; and the sooner they are exchanged for younger and more vigorous the better. In Flanders the principal crop of potatoes is planted in April. Potatoes require much manure to give a great return, although those which grow in poor soils are much pleasanter to the taste. For cattle, however, quantity is of more consequence than flavor. The soil in which potatoes are to be planted should be well prepared by deep and repeated ploughing, or what is still better, by trenching with the spade. In Flanders the sets are planted in rows two feet wide or more, and the same distance between the sets, so that each plant may have the earth drawn up to the stem, and a small hillock made round it. Sometimes the land is ploughed and manured as for other crops, excepting that the quantity of manure is at least double the quantity usually put on for corn. The sets are then dropped into holes regularly made with a blunt dibble, and filled up with earth. These sets are either small potatoes picked out for that purpose, or larger cut into pieces, taking care that there shall be at least two eyes or buds left in each piece. When potatoes are planted to any considerable extent, the method is similar to that which we described for beans, the furrows being proportionably deeper; the sets are dropped upon the dung in every second or third furrow about eighteen inches apart, and covered by the return of the plough. In this manner nine or ten bushels of potatoes will plant an acre. The crop averages about three hundred bushels, if the land is well prepared, and the potato plants have been well hoed and moulded up. This is not a very great return, considering the quantity of manure. The quality of the potatoes depends on the nature of the soil as well as on the variety planted; in light sands the potatoes are small, and mealy when boiled; in good loams they grow large and more juicy, but are not so well flavored; the latter producing a greater bulk, are preferred for cattle.

There is a potato called *Schelde Windeke* potato, from the name of a village near Alost: they grow in a strong soil and are remarkably mealy and good; but they rapidly degenerate when planted in a different soil. The potatoes which are preferred for cattle are called *Elsen Motten* and *Kattenbollen*, both very large. A variety was introduced from England into the neighborhood of Ghent some years ago, by a gentleman of the name of Lankman, which are in great repute, and go by his name. It would be difficult to point out the variety from which these sprung, as the soil in which they are transplanted has, no doubt, had a great influence on their present quality. A few small Flemish potatoes, which we once sent to a friend at Kenilworth, produced in that rich soil some of the largest potatoes we ever met with. None of the original potatoes were so large as a hen's egg.

When we were on the subject of manures, we mentioned the pond weeds as highly useful in planting potatoes. Long litter and even old thatch is excellent to plant the sets in, if the soil is not very light. Potatoes are usually taken up in the end of September; this is done by means of a three-pronged fork, which is less apt to cut the roots than the spade. The ground is at the same time cleared of the roots of couch grass, and other perennial weeds; and when the harrows have gone over the field, and all the potatoes are picked up which had escaped the fork, no other preparation is required to sow wheat, or winter barley. When the seed is sown, the stitches are marked out by the plough, the intervals dug out, and the earth is spread over the seed, after the urine cart has deposited half the usual quantity of liquid manure in these intervals. This is sufficient on land which has had a double manuring for the potatoes.

Turnips are not often cultivated as a main crop, or a substitute for the old fallows, as it is in England and Scotland; but mostly as a second crop after barley or rye, which we call *eddish turnips* in England. But as the barley and rye harvest are early in Flanders, and not an hour is lost in getting the turnip-seed sown, they are often of a very good size before winter.* The crop, however, can bear no comparison in point of weight, with a turnip crop in Norfolk, still less in Berwickshire and Northumberland; but it is obtained at a small expense, and does not interfere with any other crop. In a farm of twenty acres, if five acres were set apart every year for turnips, the remainder would scarcely give sufficient occupation to the farmer and his family, and produce sufficient corn to feed them and to pay the rent. It is by quick succession of crops that a small farm is made to produce much more in proportion than a large one, and that every member of a family is constantly and busily employed. As soon as the corn is cut, the portion of the field which is cleared is ploughed and harrowed, liquid manure is poured over it, and the seed is sown; so that in twenty-four hours an acre, which was but just cleared, is again producing a fresh crop. The ploughing and sowing goes on every day, and follows on the heels of the reapers; of such consequence may be the delay of two or three days, that the seed sown first will be out and in the rough leaf, when that which was two or three days later is only just coming up, and is subject to all the depredations of insects. When the turnips are fairly up,

* Mr. Van Aelbrock sowed some turnips in May, 1837, and they were of sufficient size in August to be given to the cows. Large turnips are not thought so sweet as the smaller, which do not give that disagreeable taste to the milk, which prevents many farmers in England from giving them to milch cows. The introduction of early turnips in Flanders might be of great advantage. If winter tares were sown to be cut in May, and turnips to follow immediately, these two crops, with the intermediate ploughing, would prepare the land admirably for wheat or colza, and not only give two useful crops; but have all the meliorating and cleansing effect of a fallow.

they are watered with diluted urine; and their growth is rapid beyond belief. We have seen turnips sown in the middle of July, after barley harvest, which in the end of August already showed very promising bulbs. If it were not for this acceleration of the growth, no crop of any weight could be raised by the end of September, when they are usually pulled up.

The cultivation of the beet-root had been introduced into Flanders under the dominion of Bonaparte, for the manufacture of sugar; it was then a forced cultivation, and was abandoned as soon as peace had restored the usual supply of sugar from the colonies; and although the revival of this manufacture in France, where considerable fortunes have been lately realized by it, has induced several speculative individuals, and also a company with a large subscribed capital to re-establish manufactories of beet-root sugar in different parts of Belgium, the Flemish farmers in general are not much disposed to raise the beet-root for sale. They imagine, whether correctly or not, that the land suffers from this crop, when there is no return of manure, as much as it would from potatoes sold off the farm, while the latter are much more profitable; and the carriage of this heavy produce to any distance through roads almost impassable in autumn greatly diminishes the return. The manufacturers of sugar have found, in consequence, that they cannot rely on a longer supply from the farmer, and that they must enter into the cultivation of the beet-root to a large extent on their own account, to keep up a proper supply. The company established near Waterloo have purchased a large tract of land, a great part of which is in woods, which they are cutting down and converting into arable land for this purpose; on this fresh soil, which is by no means rich, the beet-root appears to thrive well. A large sugar manufactory is erected at Bruges, another near Ghent, and a smaller near Dixmude, and various other places, which will require many hundreds of acres for beet-root annually, and thus make this root an important article of cultivation. The mode in which this root is cultivated has nothing peculiar in it. The land is ploughed and well manured; the seed is dibbled, as in the garden, in rows a foot or eighteen inches wide and a foot asunder in the rows; when the plants are up they are weeded and hoed by hand; the seed is put into the ground in the beginning of May, and the roots taken up in September and October. A common crop is from fifteen to twenty tons of roots from an acre of land.

This cultivation has not been adopted for a sufficient number of years to ascertain what rotation is most profitable, where beet-root is the principal object. Those who are sanguine think that alternate crops of beet-root and corn may be kept up by good tillage and manuring. The old farmers are of opinion that there will soon be a great falling-off in the crops. Time will show who are right. In the mean time the cultivation of the white and yellow beet, which contain most saccharine matter, is extending rapidly. A small portion only of these useful roots is raised for the cows. They are not supposed to be so good for the milk as turnips, and they take up the whole season. Should the cultivation be greatly extended, it may have a great effect in causing a variation in the usual rotations of crops, now generally adopted. The advantage to agriculture of the beet-root sugar manufactory, where good land is not over-abundant, is still problematical.

The *ruta baga*, or Swedish turnip, which is so highly valued by the British farmer, is not generally cultivated in Flanders. If a few small patches of it are seen, it is only as an experiment made by some rich proprietor. It does not enter into the regular system of cultivation, and is not so well suited to sandy soils as the turnip.

Carrots grow well in light soils, which have been trenched to a good depth, and they consequently form a part of the regular rotations in all light soils; when they are sown as a principal crop, it is generally next after potatoes, buckwheat, or turnips. The land, having been well stirred for these crops, is ploughed before winter, and manured with half the usual quantity of cows' dung, or of the sweepings of streets, with which is mixed a third part of pigs' dung, from the notion that the smell of this dung keeps off the moles and field mice, who otherwise would injure the crop. This is ploughed in six or seven inches deep, and the land is left so all winter. In the beginning of April, a very deep ploughing is given, two or three inches deeper than the last; twenty hogsheads of liquid manure are then poured over this, and $2\frac{1}{2}$ lbs. of carrot seed are sown. The harrows reversed are drawn over the land; the intervals between the stitches, are dug out with the spade, and the earth thrown evenly over the seed. It is slightly rolled. Some put on no dung, but only liquid manure on the land intended for carrots. If the preceding crop was potatoes, the ground is already sufficiently manured, and any additional quantity would have a tendency to produce forked carrots, which is the consequence of over manuring; but if they follow buckwheat, which has had no manure, a fresh supply is necessary to ensure a good crop of carrots. The more the manure is decomposed and intimately mixed with the soil, the better for this crop. When the carrots come up, they require to be most carefully weeded; this is the principal expense. It is done by women and children, who go on their hands and knees and pull up every weed. If carrots were sown in drills much of this labor might be spared, by using horse-hoes between the rows, and small hand hoes between the plants in the rows. Should the carrots fail, turnips or spurry are immediately sown, that no time may be lost. In May the carrots are thinned out where they grow too close, and those which are pulled out are given to the cows; they are left about six inches apart.

There are two sorts of carrots sown in the fields; the one is the large Dutch orange carrot common in England, the other is a white carrot which is very hardy, grows to a great size, and is more productive in light sands than the orange. It has lately been introduced into England; some fine specimens of the root were exhibited at the Smithfield show in December 1836. From a trial on a small scale, we are inclined to think that it will be a valuable addition to our roots for cattle in winter. The white carrot is that which is generally preferred for sowing in another crop, as flax or barley, which is a common practice. In this case the carrot seed is sown a week or two after the principal crop. The flax or corn grows faster than the carrot, which is thus kept down, and only pushes its slender root deep into the ground without making much top, or swelling to any size. In weeding care is taken not to pull out the carrots, which are easily distinguished from weeds. After the flax is pulled, the ground is gone over and weeded again; liquid manure is then spread over, and the carrots soon begin to grow, and the roots to swell. If the main crop was barley, the stubble is carefully pulled up, and the carrots are then treated as before. Thus by the middle of October a good weight of carrots is produced on land, which had already given a profitable crop that season and a great supply of winter food is obtained for the cattle. Carrots are occasionally sown amongst peas. The peas ripen in July, and are pulled up; and then the carrots are treated as we have been describing. If the row culture were introduced, and the carrots and peas drilled in alternate rows, the success would probably be more complete. This is done in the intervals of the colza or rape with good success. About fifteen small cart-loads of carrots, or about ten or twelve tons per acre, is considered a fair crop. Judging from the produce of about one-eighth of an acre of good sand, in which the white carrot was sown in England, in March 1836, without manure, the rows a foot apart and well weeded and hoed, the crop would have reached twenty-two tons per acre; the common orange carrot in the same ground did not produce half that weight.

Parsnips are sown in land too heavy for carrots; and in a deep rich loam, the produce is very great. They have the advantage of bearing the severest frost, and therefore do not require to be housed, but may be left in the ground until they are required for use. They are not thought so good for milch cows as carrots, but superior for fatting cattle. The quality of the soil must decide which of the two may be sown to most advantage.

There is another root, the cultivation of which is often very profitable, although of comparatively small use on the farm. This is chicory, of which the dried roots are roasted and used instead of coffee. A considerable commerce in this root has sprung up lately, which has caused a duty of £20 per ton to be laid on its importation into Britain. It is the same plant which Arthur Young so strongly recommended for its leaves for cattle and sheep; but it has not been found to answer the expectation in this point of view. The roots contain a strong bitter, which may be extracted by infusion; it is also used in the brewing of beer to save hops. It is wholesome, and if it does not impart an unpleasant taste to the beer, there can be no objection to its use. At all events the cultivation of it, whether for beer or coffee, is a part of Flemish agriculture, and deserves to be noticed. The seed is sown in the end of March or beginning of April. It is treated exactly as the carrot, when sown alone. The ground should be mellow and deep, rather heavy than light, and ploughed or trenched to a good depth. It is sown broad-cast in Flanders, as every thing else is; but it would be much better if it were sown in rows eighteen inches apart. The leaves may be given to sheep or pigs; but they give a bad taste to the milk of the cows who eat them. The roots are taken up in September, and are then of the size of a small carrot; they are cut into pieces, and dried in a kiln. In that state they are exported. The price varies much, according to produce and demand. It is not an object of general cultivation, but only by particular persons and in particular soils; the market is overstocked at one time, and a great demand exists at another. Such a produce can never enter into a regular course, but may be raised as circumstances may afford a prospect of sale and profit.

From the Farmers' Cabinet.

BLUE MUD.

Mr. Editor—There is an article on our salt marshes called *the blue mud*, which doubtless possesses many fertilizing properties. Several farmers have endeavored to experiment with it in their agriculture, but these have been very few, and their experiments quite limited. Where the article has been exposed to severe frost, say one winter, (the object is to pulverize it) and applied to corn in the month of May, when it is two inches out of the ground, it has had a very fine effect. The corn being three times as good where this mud was applied, than in any other portion of the field. If this article is a valuable manure, we have an inexhaustible store—and need not fear the apparent increasing poverty of our lands. The probable properties are sea-salt, oil and sulphur. Some suppose it is the washings of the upper country, having a clay basis. This seems improbable, from the fact, that when a ditch is dug, where the tide has access, it will be filled in a very short time with this substance. But what renders it difficult to determine, is the clay accompanying it; it is affirmed that the sea does not deposit that. As it will be a cheap manure, and easily obtained by every farmer, whether proprietor or rentor of land, if found to be valuable, my object is to elicit information through the pages of the Cabinet. I hope some gentleman who is acquainted with the deposits of the flood-tide, (as this is the tide bearing to our shores) will give us an essay on the subject, and whether he has thoroughly investigated it or not, any additional knowledge of its properties will be gladly received by the farmers of Kent county, Delaware. If any gentleman, having experimented with it on his land, will give us the result of the same, it may help agriculture onward. At present there is a spirit of agricultural improvement in Kent county; and a dwindling away of that prejudice so long fostered against agricultural papers, in so much, that almost every farmer is patronizing or anxious to subscribe for some good practical journal. It is therefore a matter of interest to the proprietors of the Cabinet, as well as the farming community at large, to enrich the pages of their work with articles of utility. Your friend,

A SUBSCRIBER.

Dover, Kent Co., Del. Sep. 15, 1838.

From the Farmers' Cabinet.

THE MULBERRY—SILK, ETC.

Burlington, N. J. Aug. 1, 1838.

Your letter of the 11th ult., was duly received, in which a number of interrogatories on the subject of silk-growing, &c., were addressed to me, but, by reason of other engagements, I have been obliged to delay answering them until the present time. In replying to your questions, it will be necessary for me briefly to recapitulate them. "Question 1. Have you been long engaged in cultivating the mulberry? 2. What species of morus do you deem preferable, and what kind of soil suits it best? 3. What is the best mode of propagating, planting, and managing it? 4. What is the value, expense, and profit on an acre of mulberries for the first five years inclusive? 5. What kind of worm do you consider the most valuable? 6. What help does it require to raise one hundred pounds of silk? 7. What buildings, fixtures, &c., are necessary in this latitude to raise one hundred pounds of silk? 8. What bounty or bounties does the legislature of your state offer to encourage the growth of silk? 9. Is there a ready market for cocoons and reeled silk? Any other information you may be pleased to communieate in accordance with the foregoing questions, will be thankfully received and duly appreciated." I will endeavor to give each of these questions, in their order, a fair investigation.

First. "Have you been long engaged in cultivating the mulberry?" I am one of the number who first commenced the silk-business in this vicinity, and have devoted the two last years with close application, practically, to the culture of the morus multicaulis, and rearing the silk-worm.

Second. "What species of morus do you deem preferable, and what kind of soil suits it best?" I have taken much interest during the last few years, in comparing the relative qualities of the different mulberries; and at present I know of none I deem preferable to the morus multicaulis for this and the more southern latitudes, for the silk-business. The Alpine, the Canton, and the Brussa, are excellent species, and may be well adapted to the more northern latitudes; but they are slower of growth, and less productive of foliage. Most of the different species I have seen, which are fourteen or fifteen varieties, require four or five years' growth before having much foliage to part with; but the multicaulis will yield a large quantity the first year's growth without injury to the tree, and is eaten with great avidity by the silk-worm. The mulberry that is most productive of fruit, is less productive of foliage. The multicaulis produces very little fruit, and is not often grown from the seed. It will flourish well on all soils where the peach tree does. To select a location on which to plant a field for the silk-business, I would prefer undulating grounds, having a deep mellow loam, and mixed with sand and gravel sufficient to prevent the soil from baking or crusting.

Third. "What is the best mode of propagating, planting, and managing it?" After having the ground made mellow, lay out the field in rows about four feet apart, and the surest mode, by taking one season with another, is to lay the trees down full length and cover deep enough to keep moist. The time for planting in this latitude, I think, will be during the first and second weeks in April, in common seasons. By planting a field of mulberries in this mode they must be taken up in the autumn, as they will stand too near each other to remain in the ground. But to plant a field of mulberries not to be taken up in the fall, my views are, to lay out the rows about five feet apart, and plant, in the rows, roots or cuttings two feet apart, and in the autumn take up every other tree in the rows, leaving them standing four feet apart; the remainder to have the tops cut off near the ground in the fall. The following spring, many shoots from each stump will start up with vigor, and produce abundance of foliage, and easy to be gathered. Where the field is large, I think every fifth row may be omitted and not planted, but used as a passage for a cart or wagon, in which to transport the foliage to the cocoonery. Our experiments, made this season, have proved the feasibility, that mulberries treated in the above manner, will fulfil the most sanguine anticipations.

Fourth. "What is the value, expense and profit, on an acre of mulberries for the first five years inclusive?" To answer this, it will require some philosophical speculations, as the feeding of silk-worms from an acre of multicaulis of four or five years' growth, has not been done by me, or under my observation. At the rate of fifty pounds reeled silk to the acre has been produced from the first year's growth of trees. But from an acre planted in the manner I have described, thirty pounds the first year will be a fair production, and by leaving the roots in the ground and pruning the tops in the autumn, I deem it not extravagant to estimate one hundred pounds reeled silk yearly on an average, the four succeeding years after the first year's growth of trees. After the cocooneries and fixtures for feeding are prepared, we can feed the silk-worms and reel the silk at an expense not over two dollars and fifty cents per pound, and it is then worth from four dollars and fifty cents to six dollars a pound to the manufacturer.

Fifth. "What kind of worm do you consider the most valuable?" At present, I know of none I prefer to the white mammoth worm, so called; but we have a kind that spins a large yellow cocoon, and is a very good kind. The silk of the white is worth most. We have a kind called the two-crop kind, as it can be re-produced the same year, but they spin a small cocoon.

Sixth. "What help does it require to raise one hundred pounds of silk?" It requires a person having experience to take charge of the feeding, who can manage during the first week alone after the worms hatch, and the second week a boy or girl will be wanted to pick leaves, and after that another person, equal to a full hand, will be all that will be required to finish the crop, which will be about three hundred thousand in number. By this calculation I expect the cocoonery to be convenient to the mulberry field. It requires two hands to change the worms dexterously, but they can attend to that in the morning, when the dew will be upon the leaves, and to gathering the foliage after the dew shall disappear. A stock of leaves will always be wanted before hand, lest there should be rainy weather, when they cannot gather them.

Seventh. "What buildings, fixtures, &c., are necessary in this latitude to raise one hundred pounds of silk?" Common rough made buildings will answer well to feed in. I have seen a common barn used as a cocoonery, and the silk-worms do exceedingly well. They like a gentle current of fresh air to keep them healthful. The fixtures, &c., such as we have adopted in this place for feeding, I described to you in a former letter. [See Farmers' Cabinet, Vol. II, p. 331.]

Our fixtures for spinning, are common sawed lath placed about three inches apart on the under side of the shelves, and some simple means fixed for the worms to mount up on. They spin their cocoons in the corners, where the lath comes in contact with the shelf.

Eighth. "What bounty or bounties does the legislature of your state offer to encourage the growth of silk?" The legislature of New Jersey at its last session passed a law granting fifteen cents premium, per pound, on cocoons, the production of this state, and to be in force five years.

Ninth. "Is there a regular market for cocoons and reeled silk?" There are regular markets at fair prices for cocoons produced near where manufacturing silk has now begun. The transportation of large bodies of cocoons to a distance, is not practicable. The manufacturers are anxious to obtain all the good reeled silk our country can produce at present, and for some years to come, and pay a much higher price than for the best imported. Those who raise silk and wishing to sell it in its raw state had better reel it into skeins, and it is then in a merchantable condition.

Mr. Gamaliel Gay is the inventor of a set of machinery which is now in use in this place, that first spools the silk from the cocoons, and is then doubled and twisted into sewing silk, and is thought will answer a good purpose.

I have answered your interrogatories in a manner that appears most feasible to my views, but I do not pretend to lay down any particular modes or systems as applicable to all future generations.

Respectfully yours,

CHAUNCEY STONE.

Jos. S. Naudain, M. D., Middleton, Del.

From the Farmers' Cabinet.

DON'T FORGET TO LIME.

A short time since a farmer was inquired of why he didn't use lime as a manure? His reply was, "I can't afford it."

What, can't afford to make your fields produce twice as much grain and grass as they have heretofore furnished; I don't understand that kind of logic.

Well, I don't see how I could well afford to buy lime; it costs money, you know

Yes, it costs money, that is true; and what is the use of money but to lay it out in such way as to make it produce more, in the same way that we sow wheat and plant corn, in order that we may get more wheat and corn in return.

The true plan of using money is to vest it so as to make it as productive as possible; and there is no way that I know of by which a farmer can make his funds increase faster, than by so applying them as to increase the fertility of his farm.

That wise old farmer, William West, admonished his friends and neighbors "to be kind to the soil;" well knowing from his own experience that the result would be prosperity; but those who go on skinning and impoverishing it, are acting the part of the old woman who killed the goose that laid the golden egg; they soon arrive at that state when they think—

"They can't afford to lime."

There is a class of people in the world, and some of them are called farmers, who despise small things, and therefore they can never achieve great ones; they are too proud to thrive, and too lazy to grow rich; and because they can't do things on a large scale, omit to do them altogether, and these are the people—

Who can't afford to lime.

George Esher, the worthy and successful farmer and horticulturist, who is referred to under the heading of "More fruits of industry and intelligence" in vol. ii. p. 306 of the Cabinet; humble as was the commencement of his career in life, could always afford to buy manure, because he knew that if he enriched his soil, *it* would in turn enrich him, and in this way they have been going on for half a century, conferring reciprocal benefits on each other, and it is now a question not easy to determine which is the richer, George, or his farm, for—

He never said he couldn't afford to lime.

Those who think they can't afford to lime much, should lime a little; make a beginning, for there is nothing like commencing to do right. A farmer some years since was prevailed upon to buy lime enough to dress about ten acres of his ground; this gave him a start, and the increased produce gained by this trial, has induced him to continue it since, and from that time he began to thrive, and now he thinks—

He can afford to lime.

X.

POOR RICHARD'S ALMANAC.

*The Way to Wealth, as clearly shown in the Preface of an old Pennsylvania Almanac, entitled, Poor Richard Improved.**

Courteous Reader.—I have heard, that nothing gives an author so great pleasure, as to find his works respectfully quoted by others. Judge, then, how much I must have been gratified by an incident I am going to relate to you. I stopped my horse lately, where a great number of people were collected, at an auction of merchants' goods. The hour of the sale not being come, they were conversing on the badness of the times; and one of the company called to a plain clean old man, with white locks, 'Pray, Father Abraham, what think you of the times? Will not these heavy taxes quite ruin the country? How shall we ever be able to pay them? What would you advise us to?' Father Abraham stood up, and replied, 'If you would have my advice, I will give it to you in short, "for a word to the wise is enough," as Poor Rich-

* For many years Dr. Franklin published an almanac, under the fictitious name and authorship of Richard Saunders. It was distinguished for its proverbs, and old sayings, calculated to teach habits of industry and frugality, and addressed to the taste and feelings of common people. It was much valued, and gained an individuality of character, both for itself and for "Poor Richard," as its author. The following article formed the preface to one of the last numbers; in which the author, in a manner both amusing and impressive, brings together most of the old proverbs which had been scattered through the earlier numbers of Poor Richard's Almanac.—ED. FAR. REG.

ard says.' They joined in desiring him to speak his mind, and gathering round him, he proceeded as follows:

'Friends,' says he, 'the taxes are, indeed, very heavy, and if those laid on by the government were the only ones we had to pay, we might more easily discharge them; but we have many others, and much more grievous to some of us. We are taxed twice as much by our idleness, three times as much by our pride, and four times as much by our folly; and from these taxes the commissioners cannot ease or deliver us, by allowing an abatement. However, let us hearken to good advice, and something may be done for us; "God helps them that help themselves," as poor Richard says.

'It would be thought a hard government that should tax its people one tenth part of their time, to be employed in its service; but idleness taxes many of us much more; sloth, by bringing on diseases, absolutely shortens life. "Sloth, like rust, consumes faster than labor wears, while the used key is always bright," as poor Richard says. "But dost thou love life, then do not squander time, for that is the stuff life is made of," as poor Richard says. How much more than is necessary do we spend in sleep! forgetting, that "the sleeping fox catches no poultry, and that there will be sleeping enough in the grave," as poor Richard says.

'"If time be of all things the most precious, wasting time must be," as poor Richard says, "the greatest prodigality;" since, as he elsewhere tells us, "lost time is never found again; and what we call time enough always proves little enough;" let us then up and be doing, and doing to the purpose; so by diligence shall we do more with less perplexity. "Sloth makes all things difficult, but industry all easy; and he that riseth late, must trot all day, and shall scarce overtake his business at night; while laziness travels so slowly, that poverty soon overtakes him. Drive thy business, let not that drive thee; and early to bed, early to rise, makes a man healthy, wealthy, and wise," as poor Richard says.

'So what signifies wishing and hoping for better times? We may make these times better, if we bestir ourselves. "Industry need not wish, and he that lives upon hope will die fasting. There are no gains without pains; then help hands, for I have no lands." or, if I have, they are smartly taxed. "He that hath a trade, hath an estate; and he that hath a calling, hath an office of profit and honor," as poor Richard says; but then the trade must be worked at, and the calling well followed, or neither the estate nor the office will enable us to pay our taxes. If we are industrious, we shall never starve; for, "at the working man's house, hunger looks in, but dares not enter." Nor will the bailiff or the constable enter, for "industry pays debts, while despair increaseth them." What though you have found no treasure, nor has any rich relation left you a legacy, "diligence is the mother of good luck, and God gives all things to industry. Then plough deep, while sluggards sleep, and you shall have corn to sell and to keep." Work while it is called to-day, for you know not how much you may be hindered to-morrow. "One to-day is worth two to-mor[illegible]vs," as poor Richard says; and farther. "[illegible]ave that till to-morrow, which you can do [illegible]." If you were a servant, would you not be a[illegible]ned that a good master should catch you idle? Are you then your own master? Be ashamed to catch yourself idle, when there is so much to be done for yourself, your family, your country, and your king. Handle your tools without mittins; remember, that "the cat in gloves catches no mice," as poor Richard says. It is true, there is much to be done, and perhaps you are weak-handed; but stick to it steadily, and you will see great effects, for "constant dropping wears away stones; and by diligence and patience the mouse ate in two the cable; and little strokes fell great oaks."

'Methinks I hear some of you say, "must a man afford himself no leisure?" I will tell thee, my friend, what poor Richard says; "employ thy time well if though meanest to gain leisure; and since thou art not sure of a minute, throw not away an hour." Leisure is time for doing something useful; this leisure the diligent man will obtain, but the lazy man never; for "a life of leisure and a life of laziness are two things. Many, without labor, would live by their wits only, but they break for want of stock;" whereas industry gives comfort, and plenty, and respect. "Fly pleasures, and they will follow you. The diligent spinner has a large shift; and now I have a sheep and a cow, every one bids me good-morrow."

'II. But with our industry we must likewise be steady, settled, and careful, and oversee our own affairs with our own eyes, and not trust too much to others; for, as poor Richard says,

"I never saw an oft-removed tree,
Nor yet an oft-removed family,
That throve so well as those that settled be."

And again, "three removes is as bad as a fire;" and again, "keep thy shop, and thy shop will keep thee;" and again, "if you would have your business done, go, if not, send." And again,

"He that by the plough would thrive,
Himself must either hold or drive."

And again, "the eye of the master will do more work than both his hands;" and again, "want of care does us more damage than want of knowledge," and again, "not to oversee workmen, is to leave them your purse open." Trusting too much to others' care is the ruin of many; for, "in the affairs of this world, men are saved, not by faith, but by the want of it?" but a man's own care is profitable; for, "if you would have a faithful servant, and one that you like, serve yourself. A little neglect may breed great mischief; for want of a nail the shoe was lost, and for want of a shoe the horse was lost, and for want of a horse the rider was lost," being overtaken and slain by the enemy; all for want of a little care about a horse-shoe nail.

'III. So much for industry, my friends, and attention to one's own business; but to these we must add frugality, if we would make our industry more certainly successful. A man may, if he knows not how to save as he gets, "keep his nose all his life to the grindstone, and die not worth a groat at last. A fat kitchen makes a lean will;" and

"Many estates are spent in the getting,
Since women for tea forsook spinning and knitting,
And men for punch forsook hewing and splitting."

"If you would be wealthy, think of saving, as well as of getting. The Indies have not made Spain rich, because her outgoes are greater than her incomes."

"Away then, with your expensive follies, and you will not then have so much cause to complain of hard times, heavy taxes, and chargeable families, for,

> "Women and wine, game and deceit,
> Make the wealth small, and the want great."

And farther, "what maintains one vice, would bring up two children." You may think, perhaps, that a little tea, or a little punch now and then, diet a little more costly, clothes a little finer, and a little entertainment now and then, can be no great matter; but remember, "many a little makes a mickle." Beware of little expenses; "a small leak will sink a great ship," as poor Richard says; and again, "who dainties love, shall beggars prove;" and moreover, "fools make feasts, and wise men eat them."

'Here you are all got together to this sale of fineries and nick-nacks. You call them *goods*, but if you do not take care, they will prove *evils* to some of you. You expect they will be sold cheap, and perhaps they may, for less than they cost; but, if you have no occasion for them, they must be dear to you. Remember what poor Richard says, "buy what thou hast no need of, and ere long thou shalt sell thy necessaries." And again, "at a great penny-worth pause awhile." He means, that perhaps the cheapness is apparent only, and not real; or the bargain by straitening thee in thy business, may do thee more harm than good. For in another place he says, "many have been ruined by buying good penny-worths." Again, "it is foolish to lay out money in a purchase of repentance;" and yet this folly is practised every day at auctions, for want of minding the almanac. Many a one, for the sake of finery on the back, have gone with a hungry belly, and half-starved their families; "silks and satins, scarlet and velvets, put out the kitchen fire," as poor Richard says. These are not the necessaries of life, they can scarcely be called the conveniencies; and yet, only because they look pretty, how many want to have them? By these, and other extravagancies, the genteel are reduced to poverty, and forced to borrow of those whom they formerly despised, but who, through industry and frugality, have maintained their standing; in which case it appears plainly, that "a ploughman on his legs is higher than a gentleman on his knees," as poor Richard says. Perhaps they have had a small estate left them, which they knew not the getting of; they think "it is day, and it will never be night: that a little to be spent out of so much is not worth minding; but always taking out of the meal-tub, and never putting in, soon comes to the bottom," as poor Richard says; and then, "when the well is dry, they know the worth of water." But this they might have known before, if they had taken his advice; "if you would know the value of money go and try to borrow some; for he that goes a borrowing goes a sorrowing," as poor Richard says; and indeed so does he that lends to such people, when he goes to get it again. Poor Dick farther advises, and says,

> "Fond pride of dress, is sure a curse,
> Ere fancy you consult, consult your purse."

And again, "pride is as loud a beggar as want, and a great deal more saucy." When you have bought one fine thing, you must buy ten more, that your appearance may be all of a-piece; but poor Dick says, "it is easier to suppress the first desire, than to satisfy all that follow it;" and it is as truly folly for the poor to ape the rich, as for the frog to swell in order to equal the ox.

> "Vessels large may venture more,
> But little boats should keep near shore."

It is, however, a folly soon punished; for, as poor Richard says, "pride that dines on vanity, sups on contempt; pride breakfasted with plenty dined with poverty, and supped with infamy." And, after all, of what use is this pride of appearance, for which so much is risked, so much is suffered? It cannot promote health, nor ease pain: it makes no increase of merit in the person; it creates envy, it hastens misfortune.

'But what madness must it be to *run in debt* for these superfluities? We are offered by the terms of this sale six months' credit; and that perhaps has induced some of us to attend it, because we cannot spare the ready money, and hope now to be fine without it. But ah! think what you do when you run in debt; you give to another power over your liberty. If you cannot pay at the time, you will be ashamed to see your creditor, you will be in fear when you speak to him, when you will make poor pitiful sneaking excuses, and by degrees come to lose your veracity, and sink into base, downright lying; for, "the second vice is lying; the *first* is running in debt," as poor Richard says; and again to the same purpose, "lying rides upon debt's back;" whereas a free-born Englishman ought not to be ashamed nor afraid to see or speak to any man living. But poverty often deprives a man of all spirit and virtue. "It is hard for an empty bag to stand upright." What would you think of that prince, or of that government, who should issue an edict forbidding you to dress like a gentleman or gentlewoman, on pain of imprisonment or servitude? Would you not say, that you were free, have a right to dress as you please, and that such an edict would be a breach of your privileges, and such a government tyrannical? And yet you are about to put yourself under the tyranny, when you run in debt for such dress! your creditor has authority, at his pleasure, to deprive you of your liberty, by confining you in a gaol for life, or by selling you for a servant, if you should not be able to pay him. When you have got your bargain, you may, perhaps, think little of payment; but, as poor Richard says, "creditors have better memories than debtors; creditors are a superstitious sect, great observers of set days and times." The day comes round before you are aware, and the demand is made before you are prepared to satisfy it; or, if you bear your debt in mind, the term, which at first seemed so long, will, as it lessens, appear extremely short; time will seem to have added wings to his heels as well as his shoulders. "Those have a short lent, who owe money to be paid at Easter." At present, perhaps, you may think yourselves in thriving circumstances, and that you can bear a little extravagance without injury; but

> "For age and want save while you may,
> No morning sun lasts a whole day,"

Gain may be temporary and uncertain, but ever, while you live, expense is constant and certain; and, "it is easier to build two chimneys than to keep one in fuel," as poor Richard says; so, "rather go to bed supperless than rise in debt."

"Get what you can, and what you get hold,
'Tis the stone that will turn all your lead into gold,"

And when you have got the philosopher's stone, sure you will no longer complain of bad times, or the difficulty of paying taxes.

'IV. This doctrine, my friends, is reason and wisdom; but, after all, do not depend too much upon your own industry, and frugality, and prudence, though excellent things; for they may all be blasted, without the blessing of heaven; and therefore ask that blessing humbly, and be not uncharitable to those that at present seem to want it, but comfort and help them. Remember, Job suffered, and was afterwards prosperous.

'And now, to conclude, "experience keeps a dear school, but fools will learn in no other," as poor Richard says, and scarce in that; for, it is true, "we may give advice, but we cannot give conduct:" however, remember this, "they that will not be counselled cannot be helped;" and farther, that "if you will not hear reason, she will surely rap your knuckles," as poor Richard says.

Thus the old gentleman ended his harangue. The people heard it, and approved the doctrines, and immediately practised the contrary, just as if it had been a common sermon, for the auction opened and they began to buy extravagantly. I found the good man had thoroughly studied my almanacs, and digested all I had dropped on those topics during the course of twenty-five years. The frequent mention he made of me must have tired any one else; but my vanity was wonderfully delighted with it, though I was conscious, that not a tenth part of the wisdom was my own, which he ascribed to me, but rather the gleanings that I had made of the sense of all ages and nations. However, I resolved to be the better for the echo of it; and, though I had at first determined to buy stuff for a new coat, I went away, resolved to wear my old one a little longer. Reader, if thou wilt do the same, thy profit will be as great as mine.

I am, as ever, thine to serve thee,
RICHARD SAUNDERS.

From the Farmers' Cabinet.

INDUSTRY, PROMPTNESS AND PUNCTUALITY, CROWNED WITH SUCCESS.

Stephen Girard, the great merchant and banker, was also a great and successful farmer. He owned a farm of several hundred acres of land within a few miles of Philadelphia, the cultivation of which he superintended with his usual industry and acuteness. This farm was his principal hobby; for every day, at one o'clock precisely, his gig was in waiting for him at his counting-house door, and as soon as the clock struck one he started for his farm in the Neck, not suffering any matter whatever to interfere with his daily visit. During the afternoon he gave his personal attention to the various agricultural affairs requiring it, plying his own hands to any and every kind of business that was in season. In the evening he returned to the city to lodge, and the return of day light, the next morning, would find him again engaged in the labors of his farm, which he would intermit so as to be in the city by nine o'clock to attend to his extensive and well managed commercial and banking concerns, and at one o'clock he was again on his way to his farm. He followed out this routine for twenty or thirty years, permitting no part of his business to suffer from neglect or want of attention. His farm presented a perfect model for imitation. His grain fields, grass grounds, orchard, and garden exhibited the most luxuriant and perfect appearance, while his stock of every kind, and poultry in all their varieties, were the finest and most perfect that were to be found in the country.

A distinguished foreigner, then resident in this country, on a particular occasion, had some special financial business to transact with the great banker, and 12 o'clock was fixed upon for making his visit for that purpose, but he did not arrive till the clock had struck one, he was too late, the great banker was gone to his farm, and he followed after; on his arrival he was kindly and courteously received; he was waited on over the farm and through the barn-yard, but not a word could be extracted from Mr. Girard on the subject of his mission. He could now think or talk of nothing but agriculture and rural affairs, and his friend had to return to the city and learn to be more punctual to his engagements in future.

On an occasion, many years since, the city authorities were making an improvement at Market street wharf, and there was a large quantity of rich earth, that had been accumulating there for a long series of years, to be removed, and any person was permitted to haul away as much of it as he chose without charge. It was deemed a good compost or manure, and no person knew better the value of manure than the rich merchant: he soon had his team at work removing it to his farm; an acquaintance of his who saw him superintending his work, remonstrated with him on account of the avidity and industry with which he engaged in what his friend thought so small a concern;—"Oh," says he, "Mr.——, I work to-day, if I die to-morrow." S.

From the Farmers' Cabinet.

LIME—ITS APPLICATION, &c.

On looking over the 43d No. of the Farmers' Cabinet, I find some information is elicited from me relative to the application of lime and manure, &c. "How the lime is applied? the quantity per acre? the quality of the lime? and the nature and constitution of the soil to which it was applied."

In reply to the above queries, I may state that (with one exception) for the purpose of *improving* poor land so as to produce good crops, with as little delay as possible, I have thought it best to combine the lime and manure, by applying both for the same crop; that is, in preparing for a crop of corn I should put on about 25 ox cart loads of barn yard manure to the acre, spread it evenly and plough *late* in the fall, harrowing it well before winter sets in. In the spring I spread on sixty bushels of lime to the acre, again harrowing until the ground is in good order for planting, it is then struck out lightly for planting, so as not to turn up the sward, nor is it my wish in the cultivation of the corn crop through the summer to plough so deep as to disturb the manure, preferring that it should decompose without exposure to the sun and rain. By this means it is (I believe) in a better prepared state for the wheat crop that follows. After the corn crop is taken off. I have the ground ploughed deep so as to mix the manure well with the earth, sow broadcast and harrow in. By this course I have raised from sixty to seventy bushels of corn per acre the first year, and from twenty-five to thirty bushels of wheat, following the corn crop, and from land that would not previously produce oats worth cutting. I prefer ploughing in the fall as above stated, under the impression that the eggs of insects previously deposited are in a measure destroyed by being exposed to wet and frosts of winter. By adopting this course I have never had my corn injured with the cut worm—some farmers are opposed to ploughing in the fall, because (as they say) the ground becomes grassy and difficult afterwards to keep under—this I know by experience is the fact, and the reason is a want of proper attention on the part of the farmer—if he will harrow his ground *well* directly after it is ploughed, and again in the spring, he will not be troubled with grass—at least I find it so. In harrowing in the spring, I place a weight on so as to loosen the ground to the sward, or as deep as can conveniently be done; the ground by this means is placed in good order not only for covering the corn, but gives room for the easy spreading of its fibrous roots while young and tender, and of course comes up better and stronger than when the ground is not well pulverized.

In the exception alluded to above, the lime was applied by itself, not having any manure to spare at that time. It was a lot of eleven acres of poor worn out land, and not wishing that it should lie useless, I concluded to try the effects of lime by itself—for this purpose I had the ground prepared and ploughed in the spring, and understanding that poor land would not bear much lime, I determined to ascertain that fact for my own satisfaction. I commenced putting on at the rate of one hundred bushels of fresh valley lime per acre, gradually reducing; finished at sixty bushels—the lime was slacked, and spread immediately and sown with oats, harrowing it in. The crop was unusually large, and had to be cut with the naked scythe, being all laid, (or lodged.) Where the most lime was put the crop was best, and so continued to produce in succeeding crops for many years afterwards.

The lime used in the *improvement* of my farm was from the Great Valley (in Pennsylvania) near Downingtown, which is considered of good quality for land. Of late years I have used oyster shell and Schuylkill lime—the former I have had burnt on the farm, having a kiln for that purpose. The refuse wood only is used, say at the rate of 1½ cords for 600 bushels of lime—the cost when burned does not exceed eight cents per bushel—the quantity per acre, from 150 to 200 bushels, the latter quantity I consider fully equal to 100 bushels of stone lime, and the cost less, having to give with us 25 cts. for the Valley lime. Schuylkill can be had for 17 cts. burnt with coal, or 20 cts. burnt with wood, but it is generally too much slacked by the time it reaches us, and in some instances (on being analyzed) is found to contain too great a proportion of magnesia. It would be well for our agricultural societies to turn their attention to this subject, and publish the result of their labors.

The farm on which I reside is of primitive formation—situation high—the soil naturally poor, composed of clay, sand and gravel, varying as to mixture more or less in the different fields.

EDWARD TATNALL.

Brandywine, 10th mo., 9th, 1830.

Extract From the Edinburgh Farmers' Magazine.

EARLY SOWN GRAIN HAS LESS STRAW, COMPARED TO THE GRAIN, THAN LATE.

Early sowing produces less straw than late sowing, and that in exact proportion to the times (cæteris paribus).—The knowledge of this principle which has not been discovered, at least not attended to, till within the last twenty years, is of much importance to the farmer. Before it was known and practised, the hazard of sowing land in a very high state of cultivation was very great. Oats or barley sown in such condition, at the usual period of seed time as formerly, viz. oats, late in March, and barley about the term of Whitsunday, would have been often entirely ruined by being too strong. English barley (commonly from Lincolnshire) and Dutch and many other early kinds of oats, were adopted without changing the time of sowing: and as these have a tendency to produce shorter straw, they were found of much advantage in securing a full crop without lodging. But it is found that any of our oats sown early, produce a shorter and stiffer straw, which has the same effect. Early oats, however, are still much in vogue. The Lincoln barley is almost out of repute. It is well known to some farmers, that the common Scotch barley is the best substitute for it—as, when sown early, its straw becomes shorter, much stiffer, and less apt to lodge. Potato oats are a new species introduced within these very few years; and are said to be natives of South America. It appears they were first imported into some of our Midland counties of Scotland, in a quantity extremely small; and that they obtained that name from the circumstance of their arriving in a *package of potatoes*. This is a valuable kind of oats in point of meal, yielding two to three pecks per boll more than the Angus, which, in every other respect, we reckon our best oats. They appear to be again losing ground in the estimation of some people. They are more apt than any other kind to keep the soil, like wild oats, and thereby to annoy the succeeding crops. It seems to be apprehended that, were they to be frequently shaken and ploughed in dry, that they would be as a great a weed too. They seem to have another disadvantage, which in the present circumstances of our labor, is not a small one. They ripen along with the wheat; and that article being now more than ever the chief object of the farmer, it is in danger of occasioning very serious consequences as to the timeous cutting of that crop. Potato oats are also extremely apt to shake, and seldom fail to drop in shearing. All kinds of early oats are fit only for fine land, or land in a high state of cultivation; but upon inferior land, they are the best when a bad season has thrown the seedtime too far back for common ones. Blainsley oats are our native early, and have a finer meal as well as finer straw; but they seem mostly out of favor at present. These several varieties of oats and barley afford the farmer great advantages in securing his grass-seeds, as well as his corn crop, in certain seasons and situations.

From the Farmers' Cabinet.

COOKING GRAIN FOR STOCK.

In compliance with the suggestions made in the Cabinet, several farmers have procured and put up large boilers for the purpose of cooking corn and other grain for their stock, and so far as trial has been made, it answers expectation fully. In one case two bushels of the hard Dutton corn was subjected to the operation of cooking for several hours, until it was fully expanded; it was then measured accurately, and it was found to have increased in bulk to five bushels and half a peck. This was a greater increase than was anticipated, and it is thought that the softer, lighter kinds of corn would not increase so much, perhaps not more than double, but trial has not yet been made of it.

A cask perforated with holes in the bottom, it is found, may be placed on the top of the boiler, and filled with pumpkins or potatoes, and the steaming of them may go on at the same time that corn, buckwheat, or oats is cooking in the boiler below. One farmer has adopted the plan of breaking the ears of corn into pieces three or four inches long, and then boiling or cooking them without shelling, and in that way feeding corn and cob together: his success so far in feeding some fattening cattle has been very satisfactory and encouraging.

In order to economize fuel and to procure the full effect of the heat, it is very important to have a grate under the fire, with a door to shut close where the fire is put in, so that air to supply the fire may pass in under the grate only, for where a fire is supplied with air, which passes between it and the boiler, it is constantly carrying the heat up the flue, and tends to keep the boiler cooler than it ought to be from the quantity of fuel consumed; but when the air has to pass through the fire from below, it is thoroughly heated before it comes in contact with the boiler. After the fire has burnt down so as not to need ventilation for the smoke, the flue or pipe should be closed above, and the access of air under the grate prevented by a suitable stopper or door; this prevents the circulation of cold air from conveying off the heat from the brick work and boiler, and the process of cooking will be carried on for hours after the fire has burnt down, provided the access of cold air is prevented. The fire-place should not be made larger than that of a small stove, and the brick work should be brought pretty well up to the boiler, leaving but a small space around it for the smoke to pass up. A boiler of the kind referred to, is of good value to a farmer for other purposes than cooking grain, and one of them ought to be put up on every farm in the country, and to be considered as much a fixture as a corn crib or pig pen. B.

EGGS AND POULTRY.

Among all nations, and throughout all grades of society, eggs have been a favorite food. But in all our cities, and particularly in winter, they are held at such prices that few familes can afford to use them at all; and even those who are in easy circumstances, consider them too expensive for common food.

There is no need of this. Every family or nearly every family, can, with very little trouble, have eggs in plenty during the whole year; and of all the animals domesticated for the use of man, the common dunghill fowl is capable of yielding the greatest possible profit to the owner.

In the month of November, I put apart eleven hens and cock, gave them a small chamber in a wood house, defended from storms, and with an opening to the south. Their food, water, and lime, were placed on shelves convenient for them, with warm nests and chalk nest-eggs in plenty. These hens continued to lay eggs through the winter. From these eleven hens I received an average of six eggs daily during the winter; and whenever any of them was disposed to set, viz. as soon as she began to cluck, she was separated from the others by a grated partition, and her apartment darkened; these cluckers were well attended and well fed; they could see and partially associate through their grates with the other fowls, and as soon as any of these prisoners began to sing, she was liberated, and would very soon lay eggs. It is a pleasant recreation to feed and tend a bevy of laying hens; they may be tamed so as to follow the children, and will lay in any box.

Egg shells contain lime, and in winter, when the earth is bound with frost or covered with snow, if lime is not provided for them, they will not lay, or if they do, the eggs must of necessity be without shells. Old rubbish lime, from old chimneys and old buildings, is proper, and only needs to be broken for them. They will often attempt to swallow pieces of lime plaster as large as walnuts.

I have often heard it said that wheat is the best grain for them, but I doubt it; they will sing over Indian corn with more animation than over any other grain. The singing hen will certainly lay eggs, if she finds all things agreeable to her; but the hen is much of a prude, as watchful as a weasel, and as fastidious as a hypocrite; she must, she will have secrecy and mystery about her nest; all eyes but her own must be averted; follow her or watch her, and she will forsake her nest, and stop laying; she is best pleased with a box covered at top with a backside aperture for light, and a side door by which she can escape unseen.

A farmer may keep a hundred fowls in his barn, may suffer them to trample upon and destroy his mows of wheat and other grain, and still have fewer eggs than the cottager who keeps a single dozen, who provides secret nests, chalk eggs, pounded brick, plenty of Indian corn, lime, water and gravel, for them; and who takes care that his hens are not disturbed about their nests. Three chalk eggs in a nest is better than a single nest egg, and large eggs please them; I have often smiled to see them fondle round and lay into a nest of geese eggs. Pullets will commence laying earlier in life where nests and eggs are plenty, and where other hens are cackling around them.

A dozen dunghill fowls, shut up from any other means of obtaining food, will require something more than a quart of Indian corn a day; I think fifteen bushels a year a fair provision for them. But more or less, let them always have enough by them, and after they have become habituated to find enough, at all times a plenty in their little manger, they take but a few kernels at a time, except just before retiring to roost, when they will take nearly a spoonful into their crops; but just so sure as their provision comes to them scanted or irregularly, so surely they will raven up a whole crop full at a time, and will stop laying.

A single dozen fowls, properly attended, will furnish a family with more than 2,000 eggs in a year, and 100 full grown chickens for fall and winter stores. The expense of feeding the dozen fowls will not amount to 18 bushels of Indian corn. They may be kept in cities as well as in the country, and will do as well shut up the year round as to run at large; and a grated room, well lighted, ten feet by five, partitioned from any stable or other out-house, is sufficient for the dozen fowls, with their roosting place, nests and feeding troughs.

At the proper season, viz. in the spring of the year, five or six hens will hatch at the same time, and the fifty or sixty chickens given to one hen. Two hens will take care of 100 chickens well enough, until they begin to climb their little stick roosts; they should then be separated from the hens entirely; they will wander less, and do better away from the fowls. I have often kept the chickens in my garden; they keep the May bugs and other insects away from the vines, &c.

In cases of confining fowls in summer, it should be remembered that a ground room should be chosen: or it will do just as well to set into their pen boxes of dried sand, or kiln-dried, well pulverized earth, for them to wallow in, in warm weather.

UTILITY OF THE BRITISH COUNTY AGRICULTURAL REPORTS.

Extract from the address of Sir John Sinclair to the Board of Agriculture.

County reports.—The idea of ascertaining the agricultural state of every district in the kingdom, and of printing each survey, according to one uniform model, is the greatest undertaking ever attempted by any institution; and, though carried on with funds extremely inadequate to such an attempt, yet it is at last in a fair way of being happily accomplished. All the counties in England will be completed in the course of this year. Several will remain to be done in Scotland, for the execution of which fit persons can be procured, as soon as adequate funds are obtained for that purpose. In the course of this year, five reports have been already printed, and eight transmitted to the board in a state ready for publication; so that the progress has been considerable, and the termination of this most important undertaking, by which so large a proportion of the funds of the board has hitherto been absorbed is probably at no great distance.

The advantages to be derived from these reports, are universally recognized in foreign countries; for the same plan has been already adopted in France and Russia, and will probably be imitated in every other civilized country. A letter has lately been received from a celebrated agriculturist in France, in which he states his opinion, 'that such a measure is the most useful that can be undertaken, for bringing, in a short space of time, agriculture to a high degree of perfection.'* Indeed the information furnished by the various reports and communications published by the Board, far exceeds what is generally apprehended. Dr. Coventry, Professor of Agriculture in the University of Edinburgh, who from his situation, is led to examine every work connected with the subjects on which he lectures, has recently declared, 'that in these late reports and publications, there is detailed more useful and distinct information, on various branches of agriculture, and on rural concerns in general, *than was in print before these were drawn up.*'† What then may not be expected, when all these reports are completed, for little more than one half of them were printed, when this idea of their merit and utility was formed by Dr. Coventry.

REMARKS ON THE CULTURE OF THE MORUS MULTICAULIS, AND ON SILK-CULTURE.

To the Editor of the Farmers' Register.

December 14*th*, 1838.

Dear Sir—I take the liberty, through the columns of your valuable journal, to offer to the growers of the morus multicaulis a suggestion, which, if attended to next season, will save many young trees from destruction, and, if neglected, more I fear will be lost, than can well be spared. The management of about 60,000 trees having devolved on me the past summer, and it being an entire novelty, I was induced to observe, with minute attention, the peculiarity of their growth, and to note carefully the best mode of working them. The caution I am about to give, is, therefore, the result of experience, and some little practical knowledge of the subject. It has been said, that the cultivation of the mulberry is precisely similar to the cultivation of Indian corn; this, in the outset of its tillage, is an error, and proved so fatal a one to me, that I lost several thousand young trees before I found it out. There is no plant more delicate and tender than the young mulberry, and none that requires, at the period of its germination, a nicer and more cautious management. The perennial grasses and weeds, which, in early spring, shoot up on the most highly cultivated spots, give an immediate check to its growth, and unless removed, would speedily destroy it. To free it from this evil, without injury to the young plants, is the desideratum; and as hand-weeding (on a large scale) is inadmissible, the hoe is usu-

---

* The French expressions are, 'Je crois que ce travail est le plus utile de tout ceux qu'on peut entreprendre, pour amener, dans un tres court espece de temps, l'agriculture à un grand degrè de perfection.'

† See Discourses explanatory of the Object and Plan of the Course of Lectures on Agriculture and Rural Economy, by Dr. Coventry, 1 vol. octavo, printed at Edinburgh, 1808, p. 187.

ally employed to cleanse the crop. I found that instrument, (although placed in very careful hands,) far more destructive to the trees, than either grass or weeds. You are aware, that the cutting germinates by throwing out from its extremities small and delicate roots, at first not larger, and more brittle, than the finest cambric thread; before these are strong enough to sustain themselves, the slightest touch or even jar from the hoe, will snap them asunder; when the recuperatory process, (especially in dry weather,) is so slow, that the plant perishes before it can take root again. To avoid this danger, I would recommend, as a substitute for the hoe, an instrument made similar to a pitch-fork, but having a sharp blade, in lieu of prongs; or, if economy is to be considered, an implement used by the old fashioned Virginia gardeners for weeding gravel walks, which is nothing more than a foot or two of an old scythe blade, somewhat bent to make the edge cut upwards, and fastened, midway its length, to the handle of a rake or hoe, would be equally efficient. With such a hand-skimmer, the plants can be rapidly weeded without danger of disturbing them—but whatever substitute may be considered best, I can only say, that experience has taught me that the hoe cannot be used in the field culture of mulberries without great risk, until the roots attain strength enough to resist a blow from it. In conversation the other day, on the subject of the morus multicaulis, (the prevailing topic of the day,) with an eminent eastern culturist, he informed me of a practice successfully followed by him, which appears so plausible, that I propose the next year to adopt it. If it does no good, it at least has the negative merit of doing no harm, and is therefore worthy of trial. My informer, (who is, by the way, a most respectable man, and well versed in his vocation,) says, that it has been his custom, when preparing his cuttings for planting, "to make an incision through the bark from one extremity of the cutting to the other, taking especial care not to wound the bud—the result was, that from each side of the incision roots were thrown out as well as from the extremities, thus materially aiding the growth of the tree and greatly tending to its preservation, as every new root gave an additional assurance of its living. This fact, if not erroneous, and I see no reason to doubt it, would be especially advantageous with one-bud cuttings.

While on the subject of the Chinese mulberry, I trust it will not be trespassing too far on your time and patience, to hazard a speculation as to their present extravagant value, its tendency, and probable result. That no prudent man will, or ought to purchase trees at present high prices, with a view to engage in the culture of silk, is obvious to all—and that the mulberry must in a year or two depreciate, as an article of speculation, and be only sought for as the means of making silk, is likewise susceptible of demonstration. The temptation, however, offered by the hope of a continuance of high prices, and the prospect, (however dark it may be) of realizing great profits from the sale of trees, having induced many of our most intelligent and wary farmers to engage largely in their cultivation, is, I think, a most fortunate circumstance, and will eventuate most happily for the state, by opening a source of wealth equally as abundant, and more beneficial, than ever was her tobacco trade. Nothing but this unaccountable *morimania* (if I may coin a word) could have aroused attention and stimulated inquiry into the nature and practicability of growing silk in the United States. Committees of Congress might have issued reports, and writers on silk have published volumes on the subject; but our apathetic brethren of the plough would not have read either, or given a passing thought to the matter, until awakened by the astounding fact, that a shrub six or seven feet high, raised in eight months, from a cutting six inches long, actually sold for, and *was worth* a silver dollar. This came home—curiosity and inquiry are now on the "qui vive"—and now is the accepted time for the friends of the silk business to strain every nerve to push forward its introduction. This humbug, as it is called, even by those who have been seduced into it, is certainly the most fortunate delusion that ever arose in Virginia; it is the inscrutable working of Providence to convey a blessing, which is destined to redeem this ancient commonwealth from the state of decay into which she is rapidly falling; and when the bubble of high prices for trees shall burst, as soon it must, the question will then be presented to the agriculturists, who have engaged in it from motives of speculation, and are left in the lurch—what is to be done with the stock of trees on hand, for which there is no market? Are they to be dug up and thrown away, or shall they be used for feeding silk-worms? It is not difficult to anticipate the solution self-interest will give to this query. The farmer has but to learn the fact, that in conducting this new business (for which his soil and climate are peculiarly adapted) not a single efficient laborer will be abstracted from his farm—that his barns and other buildings, (not in use during the short feeding season) will, (for want of better) answer as laboratories—that he has on hand abundant food for his worms; and above all, that the product of his care and attention will find a ready market at his door. Moreover, to give it a political cast, this grave fact is worthy the consideration of the patriotic farmer, as well as the statesman and political economist. The market in Europe for raw and manufactured silks, exceeds forty millions, and in the United States twenty millions of dollars; and to this amount are we tributary to semi-barbarous Hindoos, indolent Turks, and imbecile Italians. Now, Mr. Editor, is the auspicious moment to draw the attention of the agricultural portion of the community to this important subject. To do this effectually, permit me respectfully to suggest the creation of a state society for the encouragement of silk-growers. Such an association, with an active, influential president at his head, with its committees of correspondence, premiums, &c., would do much towards exciting attention, disseminating information, and, finally, would pave the way for the introduction of silk-making, as one of the ordinary occupations of every farm. Had I the talent of an essayist, the field is most ample, and it might be indulged to satiety; but as I do not possess it, I will close this (as you perceive) hastily written and imperfect epistle, satisfied that in leaving the subject with you, I place it in far abler hands. I am, respectfully, &c. T. M. R.

———

From the Edinburgh Farmers' Magazine.

ON THE USE OF SOAP-MAKERS' WASTE ASHES, COMMONLY CALLED SOAPERS' WASTE, AS A MANURE.

Drawn up by order of the Board of Agriculture, and published by its direction.

Introduction.—The Board of Agriculture having found, upon inquiry, that the produce of soap-makers' waste ashes, in London and its immediate neighborhood alone, amounts to above 20,000 tons *per annum*, and is likely to increase, more especially from the use of kelp having been lately introduced into the London market, which furnishes a greater quantity of refuse ashes; and being convinced, from the most accurate information, and the experience of many of its members, that this quantity of valuable manure, if brought into more general use than has hitherto been the case, would be an object of considerable importance to the national agriculture, are desirous of giving all the publicity possible to a circumstance so well deserving the attention of farmers, gardeners, hop-planters, nurserymen and others employed in the cultivation of the soil, more especially those in the neighborhood of the metropolis, and on the borders of the navigations therewith connected; and, with that view, have resolved to circulate the following observations, collected from the best information which it has hitherto been in the power of the board to obtain.

Sort of ash.—The great distinction to be found in soap-ashes, depends upon the sort of alkaline salt used by the soap-boiler. When kelp and barilla are the materials, the ashes are found to be more than twice as strong and effective as a manure, than such as are the refuse of common potash; and to this circumstance may be attributed, not only the different quantities per acre that are recommended, but also the different results which have attended the use of this dressing in different parts of the kingdom, and any failures which may have taken place. The ashes to be procured at London are all made from barilla and kelp.

Analysis.—Mr. Davy analyzed two specimens of soapers' waste (sent him by Mr. Hawes), in the laboratory of the Royal Institution, and the following was the result.

The waste from barilla gave, in 100 parts,—

Of carbonate of lime, about	76 }	
Of quick-lime, about	15 }	
Total calcareous matter,		91 parts.
Of gypsum, about		5
Of common salt		$1\frac{1}{2}$
Of carbonate of soda		$1\frac{1}{4}$

The waste from kelp, in 100 parts, gave about 94 of calcareous matter, in the same state as that from barilla; about three of gypsum, and one and a half of soluble saline matter, containing, apparently, nearly the same proportions of carbonate of soda, and of common salt, as in the former instance.

It is obvious, from the chemical nature of soapers' waste, that it will be applicable wherever calcareous matter is wanted in lands, and that it will serve the purposes of liming.

The small quantity of alkaline salt and of gypsum that it contains, will likewise render it much superior to common calcareous matter, as a top-dressing for every kind of grass.

It seems probable, that these ashes will be found of most benefit on soils that abound largely with undecomposed vegetable substances, upon which the alkaline salt will act powerfully. Charcoal also, wherever found, may be rendered miscible with water, which will produce a considerable effect. The ashes proving highly beneficial on peat-moss, and on low spongy meadows, seems to be a confirmation of this fact. On calcareous soils they may not produce an equal result, as one third of the mass of these ashes is composed of lime. They can scarcely be recommended on dry burning sands.

Such farmers as are in the habit of making composts, will probably use these ashes as a material in forming the heaps; and so far as earth is concerned, there can be no objection to the practice; but, in respect of dung, it may admit a doubt. In proportion to the quantity of alkaline matter left in the ashes, it will tend to shorten the duration of the effect of the dung; and as the addition of ashes will render stirring and mixing necessary, it merits consideration, whether the better system be not to use these manures separately. It seems advisable, in the application of these ashes to arable crops, to sow and harrow them in previously to sowing the seed, which will prevent the action of any acrid or caustic quality on the germination of the young plants. The same circumstance will point out the autumn as the proper season for applying them on grass lands, though experiments may be tried with them early in spring. Mr. Hawes, from the information which he has received, particularly from Liverpool, where they are eagerly sought after, states, that they are mixed with pond, ditch, and river mud, and used in about four months. This also agrees with the practice of Robert Thornton, Esq. of Clapham, who has used them about four years, and has thereby greatly improved a very sour pasture. In Cheshire they plough them into the land; but an Essex farmer remarks, that these ashes are of so heavy a quality, that the tillage should be shallow.

Effect.—In Surrey, these ashes have been found infallibly to kill insects, (*Malcolm's Comp.* vol. ii. p. 173.) The effect of these ashes admirable both on grass and arable (*Adam's Essay on Agriculture*, vol. i. p. 167.) Destroys slugs and vermin of every description (*Museum Rusticum.*) Mr. Mansfield, near Epping, on a poor sour pasture that would not mow, nor would stock eat it, four wagon-loads per acre effected a total change; soil strong, wet, and heavy (*Essex Rep.* vol. ii. p. 246.) Mr. Sherwood, of Abbots-Langley, Herts, has used these ashes with very great success mixed in composts. They are very serviceable in new plantations, particularly where the soil is cold. A noble lord, a member of the Board of Agriculture, possesses a grass field in Wiltshire, which was manured with soap-ashes near twenty years ago, and the improvement was very great, and has continued so ever since. Two principal farmers near Ealing, Mr. Thorne and Mr. Knivett, have used them for many years for arable land, with great success and advantage. Robert Thornton, Esq. of Clapham, in some experiments amounting to seven acres, found that these ashes added a load of hay per acre to the crop. The Marquis of Abercorn's bailiff says, his father always considered one load of soap-ashes equal to five loads of rotten dung, and particularly improved the soil and verdure. The Reverend Mr. Dudley formed, in Essex, composts of these ashes with marsh banks, which were mixed well together, and spread on grass land with great effect. Hence there is considerable reason for believing, that there is scarcely a manure to be procured, that will be found so profitable (price considered) as these ashes, and that the farmers in the vicinity of London, and of all the navigations leading from it, may embark largely in the use of this manure, without the smallest apprehension of loss by so doing; but that, on the contrary, they will find the profit decidedly great, and, by the use of them, may prevent the continual advance of all sorts of manure. Barges bringing lime, chalk, timber, bricks, malt, and corn to London, can get a freight back at twelve hours' notice.

Conclusion.—It is evident, from the preceding observations, that the use of soapers' waste is well known in various parts of the kingdom; but as the quantity of this valuable manure is likely considerably to increase owing to the more extended use of kelp in the soap manufacture, it would be desirable to have the following particulars ascertained, in a more satisfactory manner than hitherto has been the case.

1. The soils and the crops for which this manure is best calculated?
2. The quantity that should be laid on each per acre?
3. The proper period of the year for laying it on?
4. Whether any mixture should be used with soapers' waste—what is the best mixture—and the best proportions?
5. What are the effects of this article compared with other manures, and its relative value?

Any information regarding these particulars, transmitted to the Board of Agriculture, 32, Sackville street, London, will be particularly acceptable.

SOME ACCOUNT OF THE SILK CONVENTION.

To the Editor of the Farmers' Register.

In advance of a more detailed report, I propose to give you a sketch of the proceedings of the late National Silk Convention, which met in Baltimore, on the 11th of the present month.

The convention was a numerous and highly respectable and intelligent body of men, composed of delegates from a number of states. Judge Comstock, of Connecticut, was called to the chair—the duties of which he discharged with promptitude and ability. His long devotion to the objects which brought the convention together, entitled him to this mark of distinction; and the dignity and amenity of his manners fully justified the propriety of the choice.

Previous to the assembling of the convention, it was supposed by many persons, and feared by a still greater number, that it would be mostly composed of speculators in multicaulis, anxious to keep up the mania which has for some time past astonished the sober-minded portion of the community. It was thought that the ruling passion would be a desire to reap another harvest from the sale of plants, which have been sought after with an avidity proportioned to the high prices which have been demanded for them. But though there might have been, and probably were, some members of this description; yet the great majority consisted of persons anxious to promote the culture of silk, and to introduce a new and useful branch of industry into our young and thriving country. The indirect effect may, and no doubt will be, to extend the demand for the multicaulis; for the two cultures are inseparably connected; but if the multicaulis can be beneficially appropriated to its legitimate purposes, instead of being made an article of speculation, its merits will then be appreciated as an auxiliary to the silk culture; and, however extensive the demand may become, its value will no longer be factitious. This is certainly the basis on which it should be placed.

After the organization of the convention, a committee was appointed to suggest and introduce proper subjects on which its action should be had. These will appear at full in the journal of its proceedings, which will be published in the course of a few weeks. There was one subject, however, which gave rise to considerable debate, and indeed to some feeling, which it may not be improper to advert to. This was the propriety of adopting a standard reel, and recommending it to the silk-growers of the United States. The importance of this was first suggested by G. B. Smith; and upon his explanation, and that of others, it passed the committee with entire unanimity; but it was opposed in convention for a length of time, and at last was only sanctioned after some modification of the resolution. It was contended by the opponents of this measure, that it would be restricting the exercise of American ingenuity, which was believed to be fully competent to invent any machinery which the future wants of the silk-grower might require. The propriety of the recommendation, however, was fully sustained by Mr. Smith and other practical men, whose arguments, it is hoped, will be reported in full, as a stenographer took notes of the debate. The reel recommended was the *Piedmontese*, or any other combining the same principles and dimensions. And now, in the infancy of the business in this country, before we have any long-rooted prejudices to contend with; and with a view to the ultimate export of silk to Europe, it was the proper time to fix upon a standard. It was shown that before such standard was fixed in France and Italy, reels of various dimensions were in use—the result of which was so much confusion, that it was impossible manufactories could flourish. Until some specific principle was recognized in the construction of reels, no set of manufacturing machinery could be adapted to such a total want of uniformity as the raw material exhibited. At length, the subject was acted upon by the government, and the Piedmontese reel was adopted and the use of it enforced upon silk-growers by legal penalties. So accurate is this reel in its proportions, and so simple in its principles, that it was contended by Messrs. Smith, Whitmarsh and Cobb, all of whom had invented some modification of that reel, and by other gentlemen who had also been exercising their ingenuity in making improvements upon it, that the wit of man could invent nothing more simple or more perfect. The hanks reeled upon it are all of the same size; the threads of every skein are precisely of the same length; the basin and furnace are at such a distance, that the silk becomes dry by the time it is wound on the reel; and by means of the traverse bar, each filament is laid on in such a manner that it never comes in contact with the preceding one, except in crossing it. A commodity is thus produced, which, in the factory is unreeled with the same facility that it was originally reeled, and without any loss to the manufacturer. An illustration of the importance of such a standard was happily adduced by Mr. Whitmarsh, who said that he recently saw a lot of silk in New York, of very superior quality, which was brought from Brussa near Constantinople, but for which no purchaser could be found, owing to the large size of the skeins. They were eight or ten feet in diameter, and so unwieldy that no machinery in this country could work it up.

One of the leading objects of the convention was to form a "National Silk Society," to hold its meetings annually at Philadelphia, Baltimore, Washington, or some other nearly central place. The next meeting is to take place in Washington, on the 2d Tuesday in December, 1839. All the members of the convention are entitled to membership in the national society, by the payment of one dollar per annum, or membership for life, by the payment of ten dollars at any one time; and, in future, members are to be admitted on the same terms on the recommendation of the executive committee. After the formation of the national silk society, and the appointment of the executive committee to prepare business for its action, a resolution was passed authorizing the establishment of a paper to be devoted to the silk culture, and to be called the "American Silk Journal." It is to be published in Baltimore, under the editorship of J. S. Skinner, Esq., so well and favorably known to the agricultural community, as the founder and editor of the old American Farmer. The first number will probably be issued during the winter; and as the members of the silk society will make it the medium of their communications on the subjects to which it is devoted, and as it will possess facilities for concentrating silk intelligence which no other paper perhaps can enjoy in the same degree, it is anticipated that its circulation as well as usefulness will be very extensive. It will probably be a monthly of 16 to 32 pages, at one dollar per year. The surplus funds, after paying the printer and paper maker, will, in the form of premiums, be devoted to the encouragement, under proper regulations, of experiments going to establish the value and practicability of various branches of silk industry. The question, however, whether there would be any "surplus funds," and, consequently, whether this mode of encouragement would not be very likely to fail, formed the subject of considerable discussion in the committee, as well as in the society. And to remove all doubt on the subject, and to attain the ends which the committee had so anxiously in view, a liberal and very responsible gentleman of Massachusetts authorized the committee to draw upon him for the amount of any deficiency which might be found to exist. The certainty, therefore, that liberal premiums will be offered in a short time, will serve, it is hoped, to stimulate many competitors to enter the lists, not only from the north, but the south also—where, if we have the disadvantages of inexperience, we have greatly the advantage in climate. If, in this laudable contest, a generous spirit of emulation should be excited throughout the country, a variety and extent of information will be elicited, which will be interesting not only to silk-growers, but to the community at large—and which will serve to dispel all doubts in regard to the value of the silk-culture.

In addition to the establishment of a journal and the publication of the proceedings, it was ordered that an address to the people of the United States be published, the preparation of which was entrusted to an able committee, of which Mr. Smith, of Baltimore, is chairman. From the character of Mr. Smith, as well as that of the other members of the committee, the public may expect not only a well written document, but one, in the arguments and statement of which, every reliance may be placed.

The subject of bounties offered by the state legislature was also discussed, and a resolution was passed, recommending the propriety of applications to that effect, in states where no encouragement has yet been given to the silk culture. It was conceded, on all sides, that it would be improper and inexpedient to make any application to Congress; and, amongst other considerations, perhaps not the least forcible which operated against an adjournment of the convention to Washington, was an apprehension, that it might be supposed there was a desire to solicit congressional action in furtherance of their object. But, whilst the propriety of congressional legislation was repudiated, the propriety and beneficial effects of state encouragement were concurred in with great unanimity. Not that the silk-culture is supposed to stand in need of permanent fostering and propping up; but now, in the infancy of the business, when there is not sufficient skill and experience in the country to insure, in all cases, successful results, it would be manifesting nothing more than a paternal regard for the promotion of important interests, if state governments were to enact such bounties as would provide against the discouragements of total or even partial failures. The operation of these bounties might and ought to be limited to a few years, by the expiration of which time, the necessary skill and information in conducting the business, would be acquired—and at the moment when the drafts on the treasury might begin to be felt, they would cease by limitation of the act. Such bounty laws have been passed by a number of state legislatures; and the good effects have been already felt in the attention and emulation which have been thereby excited, whilst the inconveniences to the state exchequers have been scarcely felt.

During one of the sessions of the convention, a resolution was offered in compliment to the pioneers of the silk culture; and particularly to G. B. Smith, whose services were admitted by all to be pre-eminent. This resolution was passed, not only with entire unanimity, but in a manner which must have been highly gratifying to the feelings of a man of Mr. Smith's disinterestedness and modest deportment. In connexion with this expression of gratitude, I take the liberty to advert to the deep interest which was manifested by many members of the convention, in the success of the "Smith fund," according to the proposition which you recently submitted in the pages of the Farmers' Register. This was a subject which could not properly be brought before the convention; but at an informal meeting of many of its members, an opportunity was offered of presenting it to the public attention; and several influential gentlemen have undertaken to obtain subscriptions. A very important point was gained in giving it a start, and a handsome subscription was made in the course of a few moments. It is now hoped and believed that a considerable degree of success will attend the efforts of those who have interested themselves in the matter; and that the growers of the multicaulis, who have realized so much, either directly or remotely, by Mr. Smith's writings and exertions, may not now withhold the manifestation of their gratitude, which the occasion so happily offers. If the subject could only be presented in a proper point of view to each individual who has been engaged in the culture of the multicaulis, it can scarcely be supposed that he would withdraw from all participation in the offering which it is proposed to make. Many of those who have but recently engaged in the culture, may not so readily appreciate the obligations they are under to Mr. Smith, from the fact that he was strictly a pioneer in the business—and his peculiar merits, therefore, are in a great measure unknown to such as have no correct historical information of the early efforts to introduce the silk and multicaulis culture into this country. But that they are as much indebted to him as the cotton planters are to Whitney, or the country at large is to Fulton, can admit of no doubt. Mr. Smith is emphatically one of those benefactors, who, with entire disinterestedness, have devoted their energies to the public, rather than to their own particular welfare. Let not those then, who have profited by his labors—who have grown rich by his exertions and discoveries—who have reaped full and abundant harvests where he has sown the seeds; let them not in the "pride of life," forget the true author of their prosperity, and turn away from him, but for whom they might never have had their days of rejoicing.

During the recesses of the convention, there were several meetings of the members for the purpose of imparting and collecting information on the utility, advantages, and practicability of the silk-culture. These informal meetings admitted of such a latitude of discussion, such a free comparison of opinions, and practices, and results, that they were undoubtedly the most interesting and most valuable seasons which the members had the pleasure of enjoying. Those who possessed practical knowledge and wisdom, "freely gave,"—whilst those who were inexperienced, were eager to catch every word, and as "freely received." The capability of the country to produce silk of a superior quality—the relative value of the several varieties of mulberry and of silk-worms—the proper management of the latter—the practicability of rearing successive crops—the product per acre of raw silk—together with a history of the early efforts of some of the pioneers in the cause, were all enlarged upon in a manner satisfactory, impressive and frequently eloquent. In addition to which, there was a considerable exhibition of some very creditable silken goods and fabrics, manufactured from American silk during the past summer. It were wished that many others could have been auditors and spectators, on these interesting occasions. But the addresses of the various members who favored the company with their knowledge and experience, will no doubt be given very fully to the public in the report of the proceedings, which will shortly be ready for extensive circulation, and probably contained also in first number of the Silk Journal. In this expectation, there is no necessity, even if the occasion were favorable, to give even a brief abstract of the contents of the addresses.

On the whole, there is every reason to believe, that this convention will be productive of great good—that an impulse will be given to the silk-culture which will be more or less felt in the remotest parts of our country—and that it will form an epoch in the history of silk-culture, which may be remembered with emotions of satisfaction and even pride. Its practicability has been fully proved—our soil and climate have been shown to be eminently adapted to its success—and the superior intelligence of our people will no longer permit it to remain a mere matter of theory and speculation. Already have cautious and not visionary men, fixed upon the time when we shall have silk for commercial export—for it will be a much longer period before we shall have manufactories of our own for its various manipulations—and some of our contemporaries may live to see the day when we shall receive the splendid fabrics of Lyons and Spitalfields, in return for the raw silk of America. ——— ———.

AN ESSAY, PRONOUNCED BEFORE THE CUMBERLAND AGRICULTURAL SOCIETY, NOV. 30TH, 1838.

By William B. Smith, M. D.

"Can the culture of Tobacco be dispensed with in Eastern Virginia."

Mr. President, and gentlemen of the Cumberland Agricultural Society.—Before entering fully on the subject proposed, I shall take the liberty of giving a history of the tobacco plant, Nicotiana Tabacum, its medical use, &c.

Secondly, a short account of the tobacco culture in the West Indies, about the beginning of the seventeenth century.

Thirdly, the demoralizing effects of the culture of tobacco, as a staple in Virginia.

Fourthly, an attempt to prove that the time has arrived when we are under the necessity of giving up the culture of tobacco.

1st. Tobacco is an annual plant in Virginia, but in the West Indies and some parts of South America, two crops are taken from one planting. "Nicotiana Tabacum" is a native of America, and was first introduced into Europe, about the middle of the fifteenth century, or, to be more accurate, in the year 1540. Since that period, tobacco has been cultivated in various parts of Europe, for medical use, chewing, snuffing, and smoking. It has also been cultivated on the coasts of Asia and Africa; indeed we find the plant cultivated more or less throughout the whole world.

Large crops of tobacco are grown in the U. States, and exported to Europe annually. According to the Philadelphia commercial list, October 13th, the stock of Kentucky and Virginia tobacco in Europe, on the 1st January, 1837, was 40,904 hhds. In 1838, 23,464 hhds., decrease 17,430. Stock of Kentucky and Virginia tobacco in the United States, 1st January, 1837, was 26,310 hhds., in 1838, 15,835 hhds., decrease 10,475 hhds. Total deficiency of stocks in Europe and the United States, of Kentucky and Virginia tobacco, January 1st, 1838—27,905 hhds. The quantity of American tobacco required by Europe annually is one hundred thousand hogsheads. Of this quantity, from thirty to thirty-five thousand hogsheads, are of the light descriptions, or Maryland and Ohio; consequently from sixty-five to seventy thousand hhds. of heavy or Kentucky and Virginia are required to meet the consumption in Europe."

Virginia has, for the last century, furnished the European markets with the richest and best tobacco, Maryland with the finest and most delicate of fibre, and the West Indies grow tobacco remarkable for delicacy of flavor. The leaves of a well-grown plant of Virginia tobacco, are from 2 to 3 feet long, of a pale green color when fresh; and when properly cured of a yellowish cast; having a strong narcotic smell and acrid burning taste. The active constituent or principle of the plant is an essential oil, obtained by distillation. When this oil is taken in the stomach or applied to the surface of the body, it produces nausea and vomiting; it often proves violently cathartic, attended with alarming vertigo, great debility and general relaxation.

The system, however, becomes easily habituated to the use of tobacco, and it is used in large quantities as a luxury, without experiencing any other bad effect than what arises from individuals being unable to relinquish its use, after the habit of chewing is formed. When chewed in substance, it causes an increased flow of saliva, and in many instances relieves sore eyes and tooth-ache. When reduced to powder and snuffed up the nose, it proves an excellent sternutatory. The tincture of tobacco acts powerfully as a diuretic and has proved successful in dropsy and dysuria. It is also applied externally for the cure of obstinate cutaneous diseases. In the form of smoke, and infusion, it has been used with great success by way of injection in obstinate constipation of the bowels, and in the reduction of scrotal hernia.

2ndly. As we are acquainted with the culture of tobacco, in Virginia, I will pass it by and give a short account of the West India culture, one hundred and forty years ago. I do this for the purpose of showing the great difference in the Virginia and West India mode of cultivation: the latter is cultivated with far less expense, inasmuch as it will be shown, that the tobacco crop in the West Indies requires no fire in the curing process.

"After sowing tobacco seeds, the ground is watered every day, and in hot weather covered to prevent its being scorched by the rays of the sun; and when the plants are grown to a certain pitch, they are transplanted into a soil well prepared for their reception: care is also taken to keep the ground clear of weeds, and to pull off the lower leaves of the plant, that fifteen of the finest leaves may have all the nourishment. When these leaves are ripe, which is known by their breaking when bent, the stalks are cut, and left to dry 2 or 3 hours in the sun; after which they are tied together two and two, and hung on ropes under the shade to be dried in the air: and when the leaves are sufficiently dried they are pulled from the stalks, and made up in little bundles; which being steeped in sea-water, or for want thereof, in common water, are twisted in manner of ropes, and the twists formed into rolls by winding them with a kind of mill around a stick: in which condition it is imported into Europe, where it is cut by the tobacconists for smoking, chewing, formed into snuff and the like."

3dly. I will now make some remarks on the demoralizing effects of the tobacco culture in eastern Virginia. What I might ask, has produced the wretched and deplorable state of things observation presents to our view in the tobacco region of Virginia? I speak with reference to the exhausted state of our farms; lands naturally the best in the world; have become worn and exhausted by the culture of tobacco. The bitter weed has laid the forest low and left us nothing but galls, gullies and dwarf pine! If our system of agriculture be correct, how does it happen that our lands have deteriorated; and how are we to account for the fact, that in the tobacco region of Virginia, we have much steril surface; one half being unfit for cultivation, and the other half affording a scant return to the agriculturist? Let those answer the question who have cultivated tobacco. The great object heretofore has been, to get as much forest cleared as possible, make a few crops of tobacco, to be followed with grain; until the soil by hard culture and frequent washings becomes exhausted, and the land abandoned. This Virginia can witness; the system, to say the least of it, is wasteful, unproductive and immoral. Cut down, wear out and walk off, has been the system pursued in the tobacco region for the last century. The cultivation of tobacco, has not only exhausted our lands; if this was all, we could bear it, but it has left us poor; its influence is felt in eastern Virginia, and extends to our slaves, horses, cattle, sheep and hogs, and I might say down to the cats and dogs. Our ridges have become so barren, that they do not afford cover for the partridges, and they have followed the soil down branches and creeks, hovering in the flats. We should all mourn over such a state of things. Poor old Virginia! She once stood high, the pride of man, the pride of fame; now fallen. She gave birth to all that was great and good in America, she gave birth to American liberty, history, eloquence and religious freedom, and shall Virginia, the mother of 25 states, the land of Washington, the boast of Jefferson, Monroe, Madison, Marshall, Henry and a host of worthies, be reduced by injudicious culture to a CAPUT MORTUUM? Her forest has been swept away, and her great men of genius and worth, together with the hard cultivators of the soil, the bone and sinew of the land, have, by thousands and tens of thousands, been driven out of the state, in search of better lands.

Where are the talented sons of Virginia now? a few linger in the state unnoticed, many have wended their way to the north, south and west. New Jersey can boast of an Alexander, one of the most distinguished theologians in the United States. Pennsylvania can boast of a Chapman, a Gibson, and a Horner, men that do honor to the state, and the profession to which they belong, Ohio can boast of a Harrison, Kentucky a Clay, South Carolina a Waddill, and Tennessee, and all the western states, are indebted to Virginia for their distinguished men.

But we can only boast now of what Virginia has been, and the remains of her Washington and other worthies. They rest in her lap, entombed in her soil; yes, their bones are now mouldering in silent clay, and when we forget Virginia and her distinguished sons, we shall cease to live; for we are bound to the old Dominion by the tenderest ties of love and affection; the mind dwells on her scenes, with mingled sensations of pleasure and pain; but as near our hearts, and as tender as these recollections are, like all temporal things, they must be dissolved.

Perhaps Virginia has answered the great purposes for which she was intended; she may have effected her object in raising up distinguished sons, for great and mighty purposes; some of whom are now adorning other states. I am constrained to say that if a correct system of agriculture and education could have been kept up in Virginia, emigration would have been trifling in comparison to what it has been, and the old Dominion would number at this time between two and three millions.

Virginia has lost her forest, and exhausted her lands. Since the declaration of independence, 62 years ago, she has perhaps grown two millions six hundred thousand hogsheads of tobacco,* which would, if placed lengthwise, touching each other, form an extended line from New York to Liverpool, and if the average be $50 per hhd., the gross product will amount to the enormous sum of one hundred and thirty millions of dollars; deduct half for cost of culture, and there will remain sixty-five millions net. A very large portion of this money has been paid out of the state; while Virginia was engaged in making tobacco, neglecting her institutions of learning, other states were educating her sons, and the hard earnings of the planters have gone to northern schools and colleges. The old Dominion has paid in the last 50 years five millions of dollars for the education of her faculty, every dollar paid out of the state; half has been given to the Jefferson college and University of Pennsylvania; and the other half to medical schools throughout the United States and in Europe. If Richmond 50 years ago had had a university, the high character of the state would have filled the various chairs with distinguished professors; Virginia's sons would have been educated at home, the northern drain cut off, and emigration stayed, and why? Because the university would have had the support and patronage of Virginia, North Carolina, South Carolina, Georgia, the western states, and indeed the whole union; millions would have been saved, and the population of Richmond this day would exceed one hundred thousand souls.

But let us turn from this gloomy picture; has Virginia fallen never to rise again? I am not entirely prepared to answer the question, but this I will say, that the old Dominion can yet boast of distinguished, enterprising sons, men that would do honor to this, or any other age; and although she has fallen from her high estate, I say high, for her soul reached high, notwithstanding she has fallen apparently; I look forward to the time when she will rise again with renovated soil, and her worn hills and dales, galls, gullies and steril fields yield, in abundance, wine and oil, milk and honey, the finer fabrics of cotton, flax, wool and silk, together with grass, grain and lowing herds, giving to the agriculturist "a feast of fat things." Yes, this great revolution will take place; the tide of emigration will roll back, and the tobacco region in eastern Virginia, become studded with manufacturing villages and towns, and Norfolk the New York of the east. But it may be asked, what will bring about such a revolution? I answer internal improvement. Our numerous rivers, the finest in the world, connected with railroads throughout Virginia, extending their branches and arms into other states, giving facilities of travel throughout the extended bounds of the union, all connected directly with the great Atlantic seaboard, must and will produce a wonderful revolution, and that in a short time. Independent of this, eastern Virginia was intended by nature for farming and manufacturing purposes; for surely no part of the habitable globe is more highly favored with water power, or more favorable to the production of grass, grain, vines, pulse, roots and fruits. Manufacturing establishments are found at this time throughout eastern Virginia; they have taken root in Petersburg, Richmond and Alexandria, and we can but hope their march will be onward.

4thly. We come now directly to the subject before us, can we dispense with the culture of tobacco in eastern Virginia? My answer to the question is, that we can, and must give up the tobacco culture; the time has arrived when we are under the necessity of looking out for a new staple. What shall we substitute for tobacco? If called on to answer the inquiry, I would say that the silk culture in all probability will succeed the tobacco culture, and become the staple in eastern Virginia. We are in want of a permanent staple, one that will support us and reclaim our own worn and exhausted farms. I know nothing better calculated to effect this great object than the silk-culture and growing the Chinese mulberry, the MORUS MULTICAULIS.

I will now attempt to prove, that in the present exhausted state of our lands, little or no profit is derived from the cultivation of tobacco.

I shall confine myself principally to one acre of ground, and one laborer, and in making my calculations, have not taken any account of plantation tools, teams, or the value of land. Tobacco will be credited at $8 per cwt. lugs $4 50, wheat $1 per bushel, corn 80 cts. per bushel, potatoes 75 cts per bushel, pork $7 50 per cwt. beef 750 per cwt., silk $4 per lb., labor 25 cents per day.

I am aware that the prices and calculations will be found incorrect, they are given for what they are worth, with many grains of allowance. My tobacco, wheat and corn calculations are taken with alterations from similar estimates made by an able intelligent writer over the signature of "E," in the April No. of the Farmers' Register for 1837.

* Three millions hhds. is probably nearer the truth than the above statement, the gross product of which would be, at the same rate, one hundred and fifty millions of dollars. Deduct one half for cost of culture, there will remain seventy-five millions of dollars net profit. W. B. S.

I will now make an estimate of the probable expense in cultivating one acre of ground in tobacco.

Calculation 1st.

Expense of tobacco culture.

To clearing ground for plant bed 20 yards square and cutting wood four days' labor, at 25 - - - -	$1 00
To burning plant bed, hoeing, manuring and covering, four days' labor, 25	1 00
To one day's labor in fallowing -	25
To one day's labor before hilling -	25
To making 4000 tobacco hills -	1 50
To drawing 4000 plants, cutting off 4000 hills and planting, three days' labor - - - -	75
To one day's ploughing - -	25
To two days' weeding - -	50
To two days' hilling - - -	50
To one day's ploughing - -	25
To worming, three days' labor -	75
To two days' hilling - -	50
To three suckerings, three days' labor	75
To topping and priming, two days' labor - - - -	50
To cutting 4000 plants, hanging on sticks, scaffolding and housing, six days' labor - - -	1 50
To cutting and hauling wood, three days' labor - - - - -	75
To four days' firing - -	1 00
To striking down and bulking two days' labor - - - -	50
To stripping 900 pounds of tobacco eight days' labor - - -	2 00
To re-hanging, two days' labor -	50
To re-striking two days' labor -	50
To prizing 900 pounds of tobacco, six days' labor - - - - -	1 50
To carriage to market - - -	6 50
To one tobacco cask - - -	2 00
To warehouse expense - -	75
To nine cords of wood at 60 cents -	5 40
To board and clothing laborer sixty-eight days at 13 cents - -	8 84
	$40 49

Credit.

By the sale of 750 lbs. of tobacco, at $8, is	60 00	
By sale 150 lbs. of lugs at 4 50	6 75	
		66 75
Deduct expense of culture -		40 49
Net profit		$26 26

Calculation 2d.

Expense of wheat culture.

One acre of ground that will produce 900 lbs. of tobacco, will yield 20 bushels wheat.

To fallowing one acre of ground, one day's labor - - - - -	25
To harrowing same, half a day's labor	13
To one bushel seed wheat - -	1 00
To cutting and shocking, one and a half day's labor - - -	38
To hauling to barn, one day's labor	25
To threshing and fanning 20 bushels of wheat, two days' labor - -	50
To marketing 20 bushels of wheat, at 12½ cents - - - - -	2 50
To boarding servant six days -	75
	$5 76

Credit.

By sale of 20 bushels of wheat, at $1	20 00
By sale of straw and chaff from 20 bushels, at $1 - - -	1 00
Deduct cost of culture -	5 76
	$15 24

Seven acres in wheat, can be cultivated with less labor and expense than one acre in tobacco.

Calculation.

To seven acres in wheat at $5 76 expense per acre, $40 32 cents.

By yield seven acres, 20 bushels per acre, is 140 bushels, at $1 per bushel, is - - - - -	140 00
Straw and chaff from 140 bushels, at $7 - - - - -	147 00
Deduct expenses of culture	40 32
	$106 68

If the price of wheat be reduced to 90 cents per bushel, the product, including chaff and straw, will be - - - 92 68

Calculation 3rd.

Expense of corn culture.

One acre of ground that will produce 900 lbs. of tobacco, will yield 40 bushels corn.

To one day's fallowing, one day's labor - - - - -	25
To one day's ploughing before planting, one day's labor - -	25
To one day's ploughing, at the time of weeding - - - -	25
To one day's labor in weeding -	25
To one day's labor in hilling -	25
To one day's labor in ploughing -	25
To two days' labor in pulling fodder and securing - - -	50
To one day's work in cutting and securing tops - - -	25
To two days' labor in pulling and hauling corn - - - -	50
To shucking eight barrels corn, two days' work - - -	50
To carrying 40 bushels corn to market, at 12½ cents per bushel -	5 00
To boarding laborer 14 days -	1 75
	$10 00

Credit.

By sale 40 bushels corn, at 80 cents	32 00
By sale fodder from eight barrels corn	2 00
By sale shucks and tops from same -	2 00
Amounts to gross - -	$36 00
Deduct expense of culture -	10 00
Leaves net profit -	$26 00

Four acres in corn can be cultivated with less expense and labor, than would be required to cultivate one acre in tobacco.

Calculation.

To four acres in corn $10 expense per acre is $40.

By yield of four acres, 40 bushels per acre is 160 bushels at 80 cents per bushel, is - - -	128 00

Fodder, shucks and tops from same -	16
	$144 00
Deduct cost of culture [four acres]	40 00
Leaves net profit -	$104 00

If the price be reduced to 70 cents, the product, including fodder, shucks and tops, will be $88.

Calculation 4th.

Expense of potato culture.

One acre that will produce 900 lbs. tobacco, will yield 100 bushels potatoes.

To one day's fallowing - -	$00 25
To two days' preparing ground and planting - - - - -	50
To six bushels potato seed (cut) at 75 cents - - - - -	4 50
To two weedings, two days' labor -	50
To two ploughings, two days' labor -	50
To two day's labor in digging -	50
To carrying 100 bushels potatoes to market, at 12½ cents per bushel -	12 50
To boarding laborer nine days -	1 13
	$20 38

Credit.

By sale 100 bushels potatoes, at 75 cents - - - - -	75 00
Deduct expense of culture -	20 38
	$54 62

Two acres in potatoes can be cultivated with the same expense and labor that would be required to cultivate one in tobacco.

Calculation.

To two acres in potatoes, at $20 38 expense per acre, - - -	40 76
By yield of two acres, 200 bushels, at 75 cents, is - - - - -	150 00
Deduct expense of culture -	40 76
	$109 24

If the price of potatoes be reduced to 63, the product will be $85 24.

Calculation 5th.

Swine husbandry.

Expense of swine husbandry, connected with root and grain culture.

One hundred bushels of potatoes, will, with 40 bushels corn meal, fatten 12 hogs, allowing eight and a third bushels steamed potatoes, and three and a third bushels corn meal to each hog, which is more than the northern allowance.

To expense in cultivating one acre of potatoes, carriage to market deducted - - - - -	7 88
To expense in cultivating one acre in corn, carriage to market deducted -	5 00
To 12 hogs, eighteen months old, if raised on the farm, may be charged $3 50 - - - - -	42 00
	$54 88

Credit.

By sale 12 hogs, weighing 200 lbs. each, 2400 lbs. at $7 50, is -	180 00
By sale 120 lbs. lard, at 10 cents, is	12 00
	$192 00
Deduct expense - -	54 86
	$137 12

If the price of pork be reduced to $6 per cwt., the product will be, including lard, $101 12 cents.

Calculation 6th.

Beef husbandry.

Expense of beef husbandry, connected with grain and grass culture.

One acre of ground that will produce 900 lbs. of tobacco, will yield between three and four thousand pounds herd's grass hay; which will, with 40 bushels of corn meal, bring five beeves taken from the grass to market; allowing eight bushels corn meal and 800 pounds herd's grass hay to each beef.

To one day's fallowing - -	25
To one day's sowing and harrowing	25
To one bushel herd's grass seed -	75
To two days' mowing - -	50
To six days' securing and shocking, at 25 cents - - - - -	1 50
To board laborer 10 days - -	1 25
To expense in cultivating one acre in grass - - - - -	4 50
To do. do. do. one acre in corn -	5 00
To five beeves, if raised on the farm, may be charged $20 each -	100 00
	$109 50

Credit.

By sale five beeves weighing 500 lbs. each, is 2,500 lbs. at $7 50 per cwt.	187 50
By sale 150 lbs. tallow, at 13 cents	19 50
By sale of five skins, at $3 - -	15 00
By sale five tongues, at 50 cents -	2 50
By sale five heads, five viscera and 20 feet - - - - -	12 50
	237 00
Deduct expense - -	109 50
	$127 50

If the price of beef be reduced to $6 per cwt., the product, including offal, will be $90.

Silk culture.

As I have ventured the opinion that the silk-culture in Virginia, will be substituted for the culture of tobacco, I beg leave to give the following statements from the most intelligent and distinguished silk-raisers in Europe. Average gross product of an acre of ground, according to Count Dandolo, is as follows:

To 198 pounds silk at $4 per pound -	792 00
Cost of culture - -	85 10
Net profit - - -	706 90

Average gross product from an acre of ground, according to Mr. John D. Homergue, is as follows:

To 243 lbs. silk at $4 per pound is -	972 00
Cost of culture - -	111 94
Net profit - - -	860 06

The following calculation, is predicated upon the statement of Gideon B. Smith, Esq., of Baltimore, that a full grown tree, (morus multicaulis) will yield foliage enough for 5,000 worms, and as 108 trees at 20 feet square apart will stand on an acre, so will that number of trees support 540,000 worms, and as 3,000 worms will make a pound of silk, so will 540 thousand make 180 pounds at $4, which gives $720, the gross average of an acre.

We will now state an account current, by which the net profit of an acre will be clearly demonstrated, and we beg leave to make this explanation, that with a view of providing against all possible contingencies, we have taxed 540,000 worms, with the expense of the labor of one million, which will more than cover all drawbacks arising from mortality among the worms or any other unforeseen casualties.

Expense of silk culture.

To interest on one acre land, valued at twenty dollars - - - - -	1 20
To interest on laboratory valued $500	30 00
To hire two men five weeks at $6 per month - - - - - -	15 00
To their board one and a half weeks	15 00
To hire two women four weeks at $3 per month - - - -	6 00
To board two women at $1 50 per week - - - - - -	12 00
To hire four women three weeks $3 per week - - -	9 00
To their board $1 50 per week -	18 00
To hire 12 children from 7 to 14 years old, two weeks, at $1 per week -	24 00
To their board at $1 per week -	24 00
	154 20

Credit.

By sale 180 lbs. silk $4 per lb. -	720 00
Deduct cost of culture - -	154 20
Net profit - - - - -	565 80

As the above product of $720 gross is the work of five weeks only with two men, six women and twelve children, three crops of silk can be made in one year, if the culturist has 3 acres in morus multicaulis and supplies of eggs, kept in an ice-house, or some low temperature in order to prevent them from hatching until wanted.

To expense of three acres 154 20 per acre - - - - - -	462 60
Yield of 3 acres, at 180 lbs. per acre is 540 lbs. at $4 per lb. - -	2160 00
Deduct cost of culture - -	462 60
Net profit - - - -	1697 40

A table showing the actual profits of the mulberry culture, upon one, five and ten acres of ground according to the estimate of Mr. John D. Homergue.

Gross product of one acre - -	972 00
Cost of culture of one acre - -	111 94
Net profit - - - - -	860 06
Gross product of five acres - -	4,860 00
Cost of culture - - - -	559 70
Net profit - - - -	4,300 30
Gross product of 10 acres - -	9,712 00
Cost of culture - - - - -	1,119 40
Net profit - - - -	8,592 60

Estimate according to Count Dandolo, the Italian silk culturist.

Gross product of one acre - -	792 00
Cost of culture - - - -	85 10
Net profit - - - - -	706 90
Gross product of five acres - -	3,960 00
Cost of culture - - -	425 50
Net profit - - - -	3,534 50
Gross product of 10 acres - -	7,920 00
Cost of culture - - - - -	851 00
Net profit - - -	7,069 00

In a letter of the Hon. Ambrose Spencer of Albany to S. M. Hopkins, Esq., dated 7th April, 1835, he states, on the authority of the Burlington Free Press, that raw silk was produced in the town of Mansfield, Connecticut, to the amount of over $60,000 in 1834, and that the county of Windham produced silk annually valued at 500,000, and if reeled would be worth double that sum. This statement the judge believes to be substantially true.

"Near Boston, 420 pounds of silk, worth $3 50 per pound amounting to $1470 was raised by four girls, whose attention to this culture required but a small portion of the year. So says S. Blydenburg of Albany, New York. This fact contains one of the most powerful arguments in favor of the culture which we have yet seen. We find four girls—farmers' daughters, or helps, as hired persons are called to the eastward—successfully attending to four acres of mulberry trees, gathering the leaves, feeding the worms and performing all the labor incident to the business, and what is the result? Why at the depressed price of $3 50 per pound they made silk enough to bring $1470 or $367 50 to each hand; now if the present price which prevails in Massachusetts, $4 per pound from the purchaser, and 50 cents from the state, had then prevailed, each of these females would have averaged $472 25, or the whole have made, in the aggregate, $1,890, and independent of the state bounty, the 420 lbs. of silk would have brought $1680 or $420 to each of the females engaged in the feeding of the worms. And as on an average 3,000 worms completing their cocoons, will make a pound of silk, there were but 1,260,000 worms—thus it is evident, that the produce here recorded is far from being a large one, for had the orchard been planted to the extent of the capacity of the ground, 720 lbs. of silk might just as readily have been raised as the 420 lbs." But it may be said $420 to the hand is a high estimate, be it so, let us take half, which will give $210, if this is too much divide again and we have $105 to the hand, this is better than the culture of tobacco, more particularly when we consider that our worn lands are daily improving. A crop of silk is made in 5 weeks and will not interfere much with the regular business of a farm. In the silk culture all the members of a family may be employed, the young, the old, the maimed, the halt, the blind, all can gather mulberry leaves. Our tobacco barns throughout eastern Virginia will make the best laboratories or cocooneries, and nothing is wanting to prevent us from going heart and hand in the silk culture, but a few thousand mulberry trees (morus multicaulis) which may be propagated from cuttings in two years. The climate of Virginia is more favorable to the culture of silk than that of Europe, indeed it is as favorable as that of China, and the immense wealth of that country, by this culture is sufficient to convince every intelligent individual of the propriety of going into the silk culture in the tobacco region of Virginia. "We are told by a gentleman of good intelligence that the whole charge of making a pound of silk in China does not exceed more than five shillings, and almost every person, man, woman or child, may work at it, and a man or woman with a child to assist in directing the thread of the silk may with a proper machine reel from the cocoon or silk bag, 1 lb. in a day." "Now I should think the labor of slaves employed in this work would produce above twice as much as those that are employed in making either sugar, tobacco, or cotton." I wish it to be borne in mind the culture of silk in America first had its origin in Virginia, the attention of the colony was called to the subject by the British government early in the sixteenth century, and it is worthy of remark that the connoisseurs of Europe pronounced Virginia silk to be the best in the world; more glossy, soft and of a better staple than the silks of Europe or Asia.

"Mulberry trees, and printed directions were early sent to Virginia, to encourage the silk culture, and as the king, James I. had 'understood that the soil naturally yielded stores of excellent mulberries,' he gave special instructions to the Earl of Southampton to urge the cultivation of silk in the colonies in preference to tobacco 'which brings with it many disorders and inconveniences.' In accordance to which the earl wrote a letter on the subject to the governor and council of Virginia, in which he desired them to compel the colonists to plant mulberry trees. In 1623, the colonial assembly directed that they should be planted, and in 1656 the culture of silk is described as the most profitable commodity for the country, and a penalty of three lbs. of tobacco is imposed upon every planter who should fail to plant at least ten mulberry trees for every hundred acres of land in his possession. A premium also of four thousand pounds of tobacco was at the same time given to a person as an inducement to remain in the country, and prosecute the trade in silk, and the following year a premium was offered of 10,000 lbs. of tobacco to any one who should export two hundred pounds worth of the raw material of silk, and five thousand pounds of the same article to any one who should produce one thousand pounds of wound silk in one year. The act coercing the planting of a given number of trees was repealed in 1656, and renewed two years thereafter; but the system of bounties and penalties was continued until 1666, when, owing to the success of the culture, they were deemed unnecessary. While Sir William Berkley was in England on the occasion of his re-appointment as governor, in conversation with the king, his majesty strongly recommended the culture of silk, and as an inducement to the colonists to attend to his advice, mentioned that he had formerly worn some of the silk of Virginia, which he found not inferior to that raised in other countries. The encouragement given by the colonial legislature had the desired effect, a spirit of generous enterprise and emulation was infused into the minds of the agriculturists of the old Dominion, mulberry trees were generally planted and the raising of silk worms was made a part of the business of many of the farmers. Indeed so zealously did the larger planters and farmers enter into it, that many were found to come forward and claim the premium offered by the legislature; and among them was a Major Walker, a member of that body, who produced satisfactory testimony of having seventy thousand trees growing in the year 1664. The eastern part of the state abounds with white mulberry trees at present, thus affording the inhabitants the means of promptly taking up the silk culture as a portion of their system of husbandry."

Silk has been cultivated more or less in every state in the union (except Maine.) Early in the seventeenth century, silk was exported to Europe from Virginia, North Carolina, South Carolina, Georgia, Maryland, Pennsylvania and the New England states, and in 1750, two thousand five hundred lbs. of silk were raised in the neigborhood of Philadelphia.

In conclusion, I would respectfully suggest the following, for the consideration of the cultivators of tobacco in eastern Virginia—viz.: Curtail the tobacco crop one-third in 1839, two-thirds in 1840, and continue one-third for the purpose of paying for taxes, smiths' bills, iron, salt, sugar, coffee, &c. Let each tobacco culturist purchase 1000 cuttings of the Chinese mulberry (morus multicaulis) which will cost $40, to be planted as we do corn, the 1st of March, in good ground, and as there are two eyes to each cutting, under the most favorable circumstances, those cuttings will become 2000 trees from 4 to 6 feet high in November following, yielding 20 cuttings to each tree, amounting to 40,000; and if planted in like manner in March, 1840, there will be an ample supply of mulberry trees for the purpose of feeding and raising silk worms. Go into the silk culture in 1839 with the native mulberry (morus rubra,) which will give the young tyro a useful lesson in the management of silk worms. In 1840 the leaves from the scions of 2000 roots with the leaves of the native mulberry, will give a good crop of silk. In 1841 the supply of leaves will feed millions of worms and the culturist may go largely into the silk business.

MORE OF THE INTRODUCTION OF THE MORUS MULTICAULIS.

To the Editor of the Farmer's Register.

Linnæan Garden and Nurseries,
Flushing, Nov. 1, 1838.

My attention has been this day called to an article in the Richmond Enquirer, of the 12th inst., on the introduction and dissemination of the morus multicaulis.

My father, Mr. Wm. Prince, more than half a century ago, devoted great attention to the silk culture, and having, at that early period, reared many bushels of cocoons—a pair of gloves manufactured from which he still possesses—and, on my part, having imported the morus multicaulis *before it had a name*, and having urged the subject of the silk-culture for the last fourteen years—combatted its revilers in every stage, and contested for its adoption as part of the *true American system*, besides losing about $5,000, in one importation of the morus multicaulis trees, I am not content to let such flimsy statements as the one referred to, pass without a suitable rebuke; and you may calculate on receiving, in due course, a full and explicit communication on the subject.

Yours, most respectfully,

Wm. R. Prince.

December 22d, 1838.

P. S. Since writing the preceding short letter, touching the morus multicaulis, I have seen Mr. John Carter of Richmond, who, in a conversation with Mr. Garretson of this place, and myself, and without our introduction of the subject, explained to us how he first obtained the morus multicaulis. He stated, that Dr. Norton received *a tree from us in the spring of* 1838—that during the summer, he spared him a branch, with which he budded some white mulberry trees—and that this was his commencement of his culture of the tree. This is precisely as I some time since suggested to Gideon B. Smith, Esq. At that period, we were in the habit of receiving from Dr. Norton, and his friend, Dr. Hening, many native plants, collected in the vicinity of Richmond, and of transmitting them. in return, such trees or plants as they desired; and I believe I can produce from among our old papers, the original invoice of trees sent them in the fall of 1828, or spring of 1829, in which was comprised the "Philippine Island mulberry," it not having, at that early period, received the title of "morus multicaulis." Most respectfully yours,

Wm. R. Prince.

The first portion of the foregoing communication, was held back, in expectation of the more full statement, therein promised, being furnished for publication. That not having been received, the piece is now inserted, together with the postscript of a much later date. The piece in the Enquirer, which called forth this letter, was that signed "J. W.," which gave to Dr. Norton so large a share of the merit of introducing and spreading the morus multicaulis; which pretension was examined in a former article of the Farmers' Register, (No. 8,) and its total emptiness then fully exposed.

But though Mr. Prince was fully justified in his expressions, upon all the lights before him, it is proper, and but doing justice to Dr. Norton, here to state, that we have heard from a private source of a fact, of which neither Mr. Prince nor any other person who has engaged in this controversy had heard, until after the last article referred to had gone to press. This fact is, *that Dr. Norton received his first tree direct from France, in* 1828, as we understand he stated to a highly respectable gentleman, in answer to the inquiry, as to the manner by which the first plant came into his possession. This fact is one of some interest in the history of the introduction of the tree; but, if ever so well established, it would not add one particle to the strength of the claim of merit before made for Dr. Norton, if the importation was not ordered by him upon *knowledge of the plant and its value*, or if it remained long afterwards in his possession before he knew either its character or value. On these points, information is desired from Dr. Norton, or others; and if it should appear that he has not received his due credit in our former remarks and deductions from the then known facts, we shall take pleasure in rendering to him full justice.

There was an evident mistake of the pen, in the latter part of the foregoing letter, where the time of sending Dr. Norton his tree is stated by Mr. Prince to have been in "1838." The time meant to have been written, was doubtless 1828; and even in this, we infer that Mr. Prince was mistaken, as was Mr. Smith, in his former statement of the time of receiving his first tree. On this subject, the following explanation was sent, and which now can be appropriately offered.

Baltimore, Nov. 20, 1838.

I have to ask the favor of you to correct my statement as to the year when I first received the morus multicaulis. My former statement was made from memory, not supposing at the time I had any paper by which I could ascertain the exact date; but on looking over a large bundle of old letters last night, I found the letter from Mr. Prince, containing *the invoice*, in which the multicaulis tree is included. The letter is dated 11th November, 1829, and the following is the invoice:

"Morus Tartarica
"Morus alba lucida lobata
" latifolia obscura lobata
" constantinopolitana
" ovalifolia
" *Chinese*, (very large and new.)"

The "Chinese" is the one now called morus multicaulis. I was strongly under the impression that it was first sent to me under the name of "Philippine Island mulberry" by Mr. Prince; but it seems that name was given to it afterwards; and that even after that the name "morus multicaulis" was given to it. That it was not known *then* as morus multicaulis, and that its good qualities were not then known, is proved by the following remark of Mr. Prince in a letter dated October 21, 1829, advising me that he intended to send me the above trees.

"I hope, however, I may be able to aid you a little in the *silk cause*, by sending you some of the finest sorts of mulberries, particularly the celebrated *Tartarian*."

The packet that brought these trees to me sailed from New York on Saturday the 7th of November 1829; I consequently received them about the middle of that month. But you see that Mr. Prince does not allude to the Chinese tree, except in the invoice, as being any thing extraordinary; but particularly mentions the Tartarian. My old tree, therefore, has been in my possession but nine years instead of ten, (as I supposed,) and therefore it is now but ten years old.

On the 12th July, 1830, Mr. Prince wrote me as follows:

"I should have been pleased if you had stated that your Chinese mulberry tree came from me. I don't believe one tree exists in the country but yours and mine—we have about twenty."

On the 17th September, 1831, Mr. Wm. Kenrick, of Massachusetts, wrote me as follows:

"I notice you cultivate the morus multicaulis. Mr. P. wrote me last spring, (spring of 1831,) to the same purport. I have or rather am beginning to cultivate them since—*since last spring*—(spring of 1831,) otherwise except Mr. Cobb procured two plants last June of Messrs. P., it is not in New England. * * * Do you then really think that this people will ever enter into the business of raising silk?"

The above, my dear sir, fixes the date of my reception of the trees exactly. It takes off one year from the date fixed upon in my former statement, or rather makes the date one year later. I regret having fallen into the error, and hope it may be attributed to the proper cause—I could have no motive in misstating the date; and I hope this prompt correction of it will be received as evidence that I had no desire to do so. I have quoted Mr. Kenrick's letter merely to show at what time he commenced the culture of the tree.

GIDEON B. SMITH.

In addition to the above new, or supposed facts, as to the early introduction and early want of knowledge of the morus multicaulis in this country, we have obtained information of another, and previously unknown source of supply, from which alone the southern states might have been already stocked, if the value of the plant had been better known. The statement is in the following extract of a letter received from a correspondent in Georgia, dated November 11th.

"Some 8 or 10 years since, a gentleman who commenced a vineyard in Harris county, 22 miles above Columbus, sent to France for a vine-dresser; and the person engaged, M. Besson, thought it would not be amiss to bring out a few morus multicaulis, which he planted adjoining the vineyard. Owing to the worthlessness of the vines, or want of proper energy, or both, or some other cause, the vineyard was suffered to go to decay, and the Frenchman to other business. The plantation was subsequently sold to various persons, till it fell into the hands of Dr. J. W. Turner, who being a man of some taste and zeal in such matters, has revived the place to some extent, and propagated the mulberry trees left by the Frenchman, until there are 100,000, or more. A short time since, the owner's zeal growing cold, and not finding a market for his trees, he sold the land, consisting of 1000 acres, with three improvements (or settlements,) thereon, including the old vineyard and the mulberry trees, for $16000, to a gentleman of Columbus, who has a brother in Baltimore, and therefore was better informed as to the then demand for the trees. The purchaser will shortly leave here for Baltimore, to make sale of his trees, thinking he will get more there than here. Many of our citizens have lately become very anxious to procure the trees, and there is no telling where the excitement will end.

"Poor Besson is dead, and his widow lives in obscurity and indigence. So goes the world. I like your suggestions relative to G. B. Smith, and the "Gratitude" farm, and hope our fortunate citizen may be induced to contribute something; at least I hope he will not forget the poor widow of the man who laid the foundation of his fortune."

PREPARATION OF METALLIC CANDLE WICK.

Melt 100 parts of tallow, or wax, or any mixture of these, and add 5 to 10 parts of carbonate of lead well pulverized. The materials easily unite by stirring. Steep the wicks in this composition while warm and fluid. When cold the candles may be made upon them by dipping or moulding. In burning these candles, the carbonate of lead is decomposed by the heat, and little globules of lead collect on the top of the wick, which bend it out of the flame and thereby increase the beauty and brightness of the light.

[*Jour. de Conn. Usuelles.*

For the Farmers' Register.

ROUGH FIELD NOTES.

No. III.

Philadelphia and Columbia Railroad.

This work is highly important, being a link of the great improvement which is now in successful operation, connecting Philadelphia with the west. It is 83 miles long, and connects the waters of the Schuylkill at Philadelphia with those of the Susquehanna at Columbia. The highest summit crossed in this distance is the Mine Ridge, elevated 600 feet above tide, and distant 54 miles from Philadelphia. The descent to each river is made by means of an inclined plane worked by stationary power. The one at Columbia rises ninety in 1980 feet, the other at the Schuylkill is 180 feet high and about half a mile long. At the latter place the stationary engine with its room, is a model for neatness and order. The train is let down gently and safely by means of a rope three inches in diameter. The Schuylkill is crossed by a handsome covered bridge 900 feet long, on which are laid no less than four rail-way tracks.

A double track has been laid throughout the entire length of the road. The superstructure consists principally of the edge rail, supported every three feet on stone blocks, about one foot cube. Wooden sills are substituted for these cubes of stone, at intervals of 15 feet, which pass under both rails and act as ties. At each point of support the rail rests in a heavy cast iron chair, and is fastened in it by means of a small iron wedge on each side. The chair is previously fixed to the block, by means of wooden plugs driven into holes drilled into the stone. The sills and blocks are all firmly bedded on broken stone. On many of the high banks, the blocks of stone are entirely replaced by sills of wood, no doubt, to prevent inequality in settling. A portion of the road which was once laid with stone and iron plate, they are now ripping up, and substituting the superstructure just described, except that the ties are made of stone instead of wood. Though many errors of location, as well as of construction, are perceptible, yet this work may justly be placed in the first class of railroads.

The Philadelphia and Columbia railroad belongs to the state. The state owns also all the motive power. Individuals or private companies put their own coaches and burthen cars on the road, and pay to the state tolls, just as boats do on a canal. The state owning the engines which propel these wagons, has of course the regulation of the hours for starting, &c. so as effectually to guard against accident from the meeting of trains. The transportation on this road is immense. In passing over it, we met two long trains of coaches filled with passengers, and two heavy produce trains—we also overtook two long trains laden with produce and merchandise. According to the last report of the canal commissioners, this road yielded 5 per cent. while the canals of the state yielded only 3 per cent on their cost, and in addition to this the engines on it cleared $20,000 in 12 months.

It is worthy of note, that a locomotive manufactured by Norris of Philadelphia, ascended the inclined plane near the Schuylkill.

Lancaster and Harrisburg Railroad.

This road is 36 miles long, and, as its name indicates, leaves the Columbia railroad in the vicinity of Lancaster, and strikes the Susquehanna at Harrisburg. It is remarkable only for its tunnel near Elizabethtown, which is 900 feet long, and intended only for one track. This tunnel has only one shaft, which is 90 feet deep. It passes through a soft red sandstone, and is arched with brick and stone its whole length. There is evidence of much carelessness in its construction. The superstructure of this road consists of sills, bedded 5 feet apart, with rails of pine and oak, measuring 9 by 5 inches. The iron plate is $\frac{3}{4}$ inch thick. The whole road is much out of order.

In going from Philadelphia to Harrisburg, the traveller passes through the finest, and most highly cultivated portion of Pennsylvania. The fertile fields, and large substantial barns, bear mutual evidence of the annual use and convenience of the one, and great productiveness of the other.

Stonington Railroad.

Stonington is hardly known in the south, and was but little talked of, until the projection of its railroad. It is a beautiful village, containing more than 3000 inhabitants, and situated nearly in the south-eastern corner of Connecticut, on the sound opposite the eastern extremity of Long Island, and is distant 120 miles from New York. Its situation is highly pleasing. Fisher's Island is in sight to the south, and to the south-east is seen the "ocean's wide expanse." The coast is completely rock-bound, and hence the name of Stonington.

The traveller from New York to Boston has the choice of two routes. He may either take the steamboat for Providence, in which case he doubles point Judith, and encounters the roughness of sea peculiar to that promontory, or he may take the steamboat for Stonington, and thence go by the Stonington railroad to Providence, and thus avoid all the *disagreeables* of Point Judith. From Stonington to Providence the distance is 48 miles. Only one track is down, though the grading was done with a view to two. There are no large structures, though many small bridges. For twenty miles, the road passes over rocky barrens or uncultivated marshes. The country, however, improves, and thence to Providence, presents the appearance of being moderately well cultivated; the soil being light and sandy, without much scenery that is very interesting. The grading, after passing through the rocky country near Stonington, is light until the road approaches Providence. This is a new road, and the superstructure is in excellent order. It consists of the T rail, supported every three feet on wooden sills. The cross section of the rail presents a base 4 inches wide—the rail is 3 inches high.

Probably the stock of no railroad in our country is more variable than that of the Stonington road.

Boston and Providence Railroad.

This road receives all the travel both from the Stonington road and from the New York and Providence boats. Large passenger trains pass each way three times every day, and the stock is considered a permanently good one—it is paying now 12 per cent. This road is 41 miles long, with one track, laid on the same plan as the Stonington road. The chair on which the rail rests is a flat piece of iron $5\frac{1}{2}$ by 8 inches, and the rail is let into it 3-8 of an inch and confined by 4 spikes, 2 on each side. Both these roads are free from bold curvature, and no pains are spared to keep them well drained. Besides the longitudinal drains on the sides, there are little cross grips every 15 or 20 feet. Besides the wooden bridge across the Pawtucket near Providence, and a stone one about 14 miles from Boston, there is no other structure of moment. The grading is light, through a soil generally sandy. I passed from Stonington to Boston, 89 miles, in four and a half hours, and never travelled more smoothly. The railway throughout is in the finest order. After leaving Providence, the country continues uninteresting, until near Boston, elegant country houses and fine gardens are seen all around.

Boston and Lowell Railroad.

The Massachusetts railroads are decidedly the finest in this country. The necessity of obviating the ill effects of the severe frosts, causes them to be built in the heaviest and most permanent manner. Like all the other railroads leaving Boston, this crosses the marsh, which makes Boston so nearly an island, by means of long trestle work. From Boston to Lowell, the distance is 26 miles, and there are two tracks nearly all the way. Both the T and fish-bellied rail is in use; the former preferred. The rail rests on stone sills, firmly bedded, 3 feet apart. These sills or sleepers are 8 to 10 inches wide, and at the joints of rails as much as 12 inches, and in some cases, rest on parallel walls of masonry, sunk sufficiently low not to be affected by the frost. The sleepers sometimes alternate with cubes of stone, but not often. When the fish-bellied rail is used, it rests in chairs on every sill, like those used on the Philadelphia and Columbia railway. The T rail is let into the stone sill 3-8 of an inch, and confined by spikes. Between the chair and stone, thin slips of wood have been introduced, but this does not prevent the disagreeable jarring which seems incidental to all stone and iron roads. All the road bridges across this road, as well as the Stonington and Providence roads, have expensive abutments of masonry. There is no viaduct or other structure of moment. The grades are very gentle, probably in no case exceeding 10 feet to the mile.

The income of this road is derived from travel, and from the transportation of the raw material to, and of the manufactures from Lowell. An idea of the business of this road will be best formed from the statistics of Lowell.

Lowell is a new looking town, with unpaved streets, which has sprung up on the banks of the Merrimack, to the water-power of which it owes its origin, as well as its rapidly increasing population. Its manufactures are so extensive that it has been termed the "Manchester of America."

There are not fewer than 26 extensive establishments for the manufacture and printing of cotton goods, and the manufacture of carpets and other woollen goods, whose agregate capital is not much short of $10,000,000, and which engage not many less than 10,000 operatives and superintendents. There are nearly 5000 looms and more than 160,000 spindles in continual operation, which produce, annually, the rise of 51 millions of yards, and consume more than 16 millions of pounds. Nearly 4,000 barrels of flour are annually consumed to make starch, of which 500,000 lbs. are used in sizing, &c. The wages of the operatives amount each month to more than $100,000. The manufacture of locomotives and divers other smaller matters is also carried on. Lowell now contains upwards of 20,000 inhabitants, and it was only about 16 years ago that the first factory was established.

Query. Had Richmond, with its unlimited water-power, (a water-power as far superior to that of the Merrimack as the energy of the people of the north is to that of the people of the south,) been in the hands of the citizens of Massachusetts for the last 30 years, what would now be its extent, its wealth, its resources, its population?

At Lowell a stranger, particularly a southerner, meets with no difficulty in gaining admission into any of the factories. I found this the case throughout the north. The general appearance of good health and happy looks among the hands are no less a source of gratification than the extensive factories themselves.

When we consider the immense intercourse which must exist between Boston and a place of this sort, only 26 miles distant, the quantity of material and manufactures, and merchandise, which must be carried from one to the other, we may form some idea of the business of the Boston and Lowell road. It is regularly dividing 12 per cent. and could easily divide more, but for the folly of the state legislature, (fully exemplified in this case,) which requires that the dividends shall be limited to 12 per cent. and that all over and above that amount shall be paid as a tax to the state. The company, however, waste all the surplus revenue in making alterations, &c., in their road, which are not called for, or so little so that they would never be made, were the stockholders permitted to pocket what they justly consider ought to be their own.

Lowell and Nashua Railroad.

On arriving at Lowell, I found this road just opened. It extends from Lowell along the southern bank of the Merrimack, 15 miles to Nashua, which is a village just within the southern border of New Hampshire. The lattice bridge by which the road is to cross the river to reach Nashua, which is on the opposite side of the river, is not yet finished.

This road, 15 miles long, cost $300,000 and is built on an excellent plan, and is now in good order. The superstructure consists of wooden sills, placed as cross ties, 3 feet from centre to centre, and resting on two parallel string pieces of 3 inch chestnut plank, placed longitudinally beneath each rail. Where these planks abut one against the other, the joint comes over the centre of a board four feet long, giving a lap of two feet to each plank, and thus effectually preventing the extremity of one string piece from settling below that of the other. On the cross sills rests a heavy T rail, the cross section of which is 4 inches high, and has a base 4 inches wide. This rail weighs at least 2 lbs. to the lineal yard, more than any rail which has been yet imported. The chair by which it is confined to the sills is the same as that used on the Providence and Stonington roads. The grading was light, and there is no heavy structure besides the bridge mentioned at Nashua.

Boston and Worcester Railroad.

Like the other roads radiating from Boston, this ranks with the first class of railroads in this country, both in point of construction and the amount of its business. It is 42 miles long—route direct—curvatures easy, with some deep cuts, but principally through sand. The edge rail is used, supported every 3 feet, generally on wooden sills, but sometimes on stone blocks. The rail rests on a chair similar to that in use on the Philadelphia and Columbia road.

From Worcester, the present termination of this road, a railway by next summer will be in operation, extending westward to the banks of the Hudson, by which means a new route will be opened for travellers from New York to Boston, viz. by steamboat up the Hudson to the terminus of this new road, (which will most probably be Hudson City,) and thence by railway through the heart of Massachusetts to Boston. By this means the Boston and Worcester road will be enabled to come into competition with the Boston and Providence road for this immense travel, and its revenue, already large, will be greatly increased. The eight-wheeled coach does not seem yet to be much in use in this state, but on all the roads the coaches, though on the four-wheel principle, are elegant in point of style, and delightful in point of comfort.

The three great and important roads, namely, the Providence, Lowell and Worcester, were chartered in 1830 and 1831. They cost a great deal of money, but have been completed in a style which will render them permanent and useful. They do credit to their projectors and constructors, and are justly the pride of Massachusetts.

ANSWER TO "PRINCEANA." REMARKS ON MULBERRY AND SILK-CULTURE.

To the Editor of the Farmers' Register.

It was not until to-day that we saw the article in your paper, signed "Anti-puff," and which bears some marks of having emanated from a source, where the writer was not disinclined to benefit your sales of trees, &c. A question may, perchance, arise in some minds, whether it is the most especial duty of an editor to admit communications to his paper, which are particularly calculated to advance his own personal interest, by attacking those of his subscribers and advertisers, whose business avocations may happen to come into collision with his own; as there may be some persons so ill natured as to presume, that he is not totally adverse to their admission. Your paper has always received from us what little aid we could bestow by recommending it to our friends, and it has been with pleasure that we have marked its rapid advancement—but permit us to say, that since its editor has entered the arena, as a vender of mulberry trees, we have had a suspicion that he did not manifest quite as much of that absolute disinterestedness for which he was formerly so distinguished. One might suppose that with his commendable spirit, he would feel contented at pressing forward so rapidly to the goal, and with being on the point of seizing the golden prize, without caring to cast any Parthian arrows on his less worthy and less successful competitors, who seem almost concealed by the obscurity of their distance. Permit us, sir, in illustration, to quote from the advertisement in your "Country Advertiser," in which you say as follows: "The great superiority of the multicaulis plants and cuttings, (referring to those you advertise,*) in luxuriancy of growth and as stock to raise from, is now universally acknowledged by the northern dealers, and that ground of preference is stated in their advertisements of southern plants for sale." Now, sir, we will not adopt the words used in your paper, and state that this assertion "is grossly and manifestly false," but we do appeal to the silk culturists of Burlington and Philadelphia, and to other northern dealers generally, whether it is not notorious that the southern trees offered for sale the last season, could not be sold for near the price of northern trees, arising from the great preference given to trees of northern growth, and so far from its being stated in the advertisement of southern trees "as a ground of preference," it would have been a manifest injury, and we have never yet seen any but *southern* advertisements that ventured such an assertion. We wish not to undervalue the trees grown in Virginia, they are among the best of their kind; but it is yourself, who, from erroneous conceptions, have become the aggressor, in seeking to benefit your own sales, by depreciating, as you say in your advertisement, "the whole crop raised north of Philadelphia;" whereas, for our part, we act only on the *defensive*, and seek but to counteract your erroneous denunciations, made in the double capacity of advertiser and editor, and this we do without attacking any one, and without entitling them ***Ruffiniania.*** In our plantations, which the last season covered about twenty acres, we did not use one southern tree or cutting, and the southern plantations, we presume, have all originated from the trees first imported, propagated, and disseminated by us. Now, sir, as to the wager and competition, which "Mr. Anti-puff" might much better have accepted than to have ingeniously eluded by an attack, we are willing to meet him on what he declares to be the worst position. We will take 2000 trees of one year's growth, without any selection, from a parcel *grown in Connecticut*, and which are now just as they grew; and he may take a similar number of trees, of the same age, grown in your state by him, by you, or any of your friends, he also taking them as they grew, without selection; and we will agree to measure the average girth and height of the main stalk or body, and the length and number of buds on the branches, and the parcel which possesses the superiority in a majority of these points, shall be entitled to the benefits of our proposition. This is a plain offer, and although we may be unsuccessful, it will at least serve to show that the valley of the Connecticut is not to be despised, and that the writer in your paper is ignorant of the fact, that the average growth of the morus multicaulis, in that valley, the present season, was equal to the growth in Maryland and Virginia. You will perceive we spoke but of Rhode Island and Connecticut in our notice, but he equivocates and contrasts *all New England* with Virginia, to give a semblance of what is not the fact, that we had included it all in our assertion.

Having now gone through the actual business part of our communication, we will make some few general remarks on the mulberry culture. It is well known that climate is greatly ameliorated when in proximity with the ocean, and our remarks relative to Rhode Island, Connecticut, and Long Island, were based upon this fact. We did not at all refer to the country in the interior, and you will perceive, therefore, that there is not so much difference in our views, as might at first be supposed. The peach, which is a native of Persia, has made growths here of 9 feet in a single season. Trees of the morus multicaulis, planted in our grounds after the 10th of June, attained in many instances a height of 6½ to 7 feet, and although our trees and cuttings were planted very late, and not completed till the middle of June, we have raised above 200,000 trees, measuring from 4 to 7 feet in height, and there were several other plantations in this vicinity in which the trees were 6 to 7 feet in height. Trees, like mankind, become by degrees acclimated, and we, this summer, saw some large morus multicaulis trees in the garden of Mr. Bestor of Suffield, Connecticut, which occupied a high exposed position, and had been growing there for years, without the least injury, and we witnessed the same fact at Mr. Kenrick's nursery, near Boston. The more completely a tree becomes hardened to climate, the more sure it is to succeed. The Catalpa, Ailanthus, Pride of India, &c., brought from the south, are prone to continue their growth to a much later period than the same kinds of trees of northern growth, and consequently are injured by our frosts before their wood is matured. But northern trees sent to the south are sure to succeed, and to attain their utmost development. The difference between the climate of Maryland and Virginia, and of this vicinity, is very trivial, and we refer more particularly to South Carolina, Georgia, and the states south of them in our preceding remarks. In those states where the contrast of climate and seasons is very great when compared with the north, the multicaulis will of course attain a greater height and development than in the more northern states. This is a point on which I presume there exists no actual difference of opinion.

* *None* were advertised for sale, and therefore the writer's shaft is entirely misdirected. In the advertisement in question, (which may be seen also on the covers of the 7th and 8th Nos. of Far. Reg.) it was merely proposed to cultivate buds or cuttings on shares for the owners—offering to return either 3 for 1 furnished, certain, or two-thirds of the whole crop. Either of these bargains Mr. Prince would do well to make for his own cuttings with any careful cultivator in lower Virginia; and we suspect that there would be insuperable objections, with both parties, to such a contract being made for cultivation in the *Linnæan Gardens and Nurseries.*—Ed. Far. Reg.

We will now conclude, by a word to our fellow-laborers in the same pursuit, the silk culture; the field for our operations is immense and wide enough for us all. The object is a great national one, and forms part of the *true American system*. We approve of the argument recently advanced, that every one who derives profit from the cultivation of his trees, is bound to do more, and to expend a portion of earnings in a cocoonery, at least, if not in a manufactory. *We intend to do both*, and we wish none other but that friendly and rational competition which shall develope itself by presenting the most plainly and satisfactorily to the American people, the ease and simplicity of every department of the silk culture. You have yourself been a most efficient and valuable pioneer in the cause, and no one is more willing to render you homage therefor than ourselves. Your paper has diffused the most useful information far and wide, and has awakened in enlightened Virginia, that spirit which was but latent, and which it required only your pen to illume. Our friends Gideon B. Smith, Dr. Norton, T. S. Pleasants, John Carter, General Cocke, Luther J. Cox, E. P. Roberts, Rev. D. V. McLean, the Messrs. Cheney, and a host of others have thrown the whole weight of their talents into the general cause, and what results may we not anticipate from their exertions, and from the spirit which now pervades all classes? Do Americans, when they undertake a great object, allow themselves to be surpassed by any other nation. Does our mighty country, embracing every variety of climate that all the silk countries of the world can boast, shrink from a competition calculated to develop her immense advantages, and to render her independent of foreign importations, which have in a single year drained her of above twenty millions of dollars? We answer firmly in the negative, and declare our absolute conviction, that such are the advantages of our climate, such the energy and industry of our citizens, such their tact in the invention of suitable machinery, and last, though not least, such the advantages of the multicaulis tree over every other variety in accomplishing that most important point, *the economy of labor*, that within five years our country will command the balance of the silk trade in its favor, and become a great silk exporting country.

Yours, most respectfully,

WM. PRINCE & SONS.

Linnæan Gardens, Flushing, Nov. 17, 1838.

P. S. We hope soon to have a paper on the silk culture published here, and we are preparing a lengthy article explanatory of the silk culture, *to be distributed gratis*, in which we shall comment also on the introduction and dissemination of the morus multicaulis, and show the immense numbers we have imported and propagated, including 54,000 that were thrown into the New York dock, in the winter of 1835—36, on account of their being totally rotten from the voyage.

To the Editor of the Farmers' Register.

THE MARL INDICATOR.

I beg leave to call your attention to a striking difference between the drawing, in your November number, of the plant which you call "*The Marl Indicator*," and the decription of it by one of your botanical friends. It seems that both he and the artist who drew it had the plant itself before them. One or the other, therefore, must have examined it too carelessly, or such a mistake could not possibly have happened. But the consequence is, that those who never saw the plant are no wiser now, than they were before your paper came out. Again, your friend, Mr. Gideon B. Smith, has made the matter rather worse, by declaring, (as you quote his letter,) that "*the description of the plant and the drawi g agree perfectly*," &c. Now, what is the fact? Why, the description says, it has "*leaves opposite amplexicaul*," whereas, the drawing shows leaves connected with the stalk or stem, in the common way, at a point.

Probably, my good sir, I should never have found out this blunder, but being no botanist myself, yet very desirous of knowing every thing about this extraordinary plant which I could understand, I set to work, with a botanical dictionary, to hunt out, as well as I could, the meaning of all the cramp, puzzling words which I found in your friend's description. When I came to "*amplexicaul*," the dictionary thus explains: "*having the base surrounding or embracing the stalk;*" but on turning over to the drawing, I could make out nothing like it—unless, indeed, the words "*surround*" and "*embrace*" mean something very different in botany from what they do in common parlance. In this annoying quandary I have deemed it best to submit the matter to your arbitrament, in the confident hope that you will beg your botanical friends, in behalf of all who have no knowledge of their truly delightful science, to take a little more pains the next time they undertake to indoctrinate such ignoramuses as your old friend COMMENTATOR.

[The error stated above really exists; but it was not made in the botanical description of the plant, nor by the engraver, but by the artist who designed and colored the picture. The very slight difference (to the view, though important as a botanical characteristic,) escaped his observation, as it did in the engraving that of all other persons, until subjected to the microscopic scrutiny of our friend Commentator.]

TO SUBSCRIBERS, AND THE PUBLIC.

The attention of the subscribers to the Farmers' Register, and of the agricultural community in general, is respectfully requested to be given to the annexed conditions of publication, for Vol. VII; and especially to the reduction of the cost of subscription, by one half, to every individual who may choose to comply with the easy conditions annexed to that benefit. Each subscriber now on the list, who has paid \$5 in advance for Vol. VII, or who shall pay in due time and the manner specified, may order, and have sent to the address of a *new* subscriber, a second copy of the same volume, without further charge. And for a like remittance of $5, made in advance, or at the time of the order, any two new subscribers will be furnished with a copy for each. Thus, while no single subscription or payment will be for less than $5, the price, in effect, will be reduced to $2 50 the copy, to every subscriber, old or new, who will unite with one other new one in a joint payment for two copies.

This offer, if ineffectual, will be the last of several different attempts made by the proprietor, for the purpose of inducing the agricultural public to aid his efforts to furnish the Farmers' Register at a lower price than any valuable publication has ever been issued in the southern states. Heretofore these offers and efforts have met with no effectual response. This one will, and must be, final. If fully availed of by subscribers now, and also hereafter, upon similar conditions, the proprietor will be sufficiently compensated for the great reduction of price, by a greatly increased issue, and the publication can be continued to be obtained hereafter, on the like conditions, at half the regular cost, heretofore. To furnish the new subscribers now expected, it is necessary to commence, and continue, even if that expectation should not be realized, an additional and extra impression of the work of more than double the amount of its present and usual issue; and it will require that all this additional supply shall be absorbed by additional and increased demand, to prevent loss to the publisher from the change. Nevertheless, he has determined to encounter the risk of such loss; and having commenced the course, and taken the first step, he is fully committed to the completion; and cannot, without still greater loss, retrace his steps, or avoid bearing the full expense. Should the offer be properly appreciated by the agriculturists of the southern states, and the necessary support be offered for so cheap a publication, then both its permanency and its continued cheapness will be secured. But if less should be the result, it will be the last of the risks and many and heavy personal sacrifices made by the editor and proprietor, for the purpose of bringing into existence, and establishing, and maintaining the usefulness of the Farmers' Register, through all difficulties, and all the numerous sources of vexation and annoyance which can scarcely be compensated by pecuniary profit, and which have been increasing more and more from the commencement of this enterprise to the present time. The most important of these inflictions, the costly and most disagreeable connexion with hundreds of non-paying subscribers and "*patrons*," it is hoped will be effectually removed by the sacrifice now offered to be made in greatly increased expenditure for advanced or prompt and sure payments.

From the first commencement of this publication, reduced prices have been fixed for joint and advanced payments, and especially for such as brought in new subscribers. The last and most considerable reductions, offered last year, were by some old subscribers so misconstrued, as to be considered as bearing unjustly and disadvantageously on their class. As the like misconception, however groundless, may attend the still more liberal, and more easily available deductions now offered, the editor asks leave, for full explanation, and for the first, and as he hopes, the last time, to obtrude upon his readers in general, some of the small matters of personal and private interest and concernment, which must necessarily, and at length, he brought forward.

Ever since this publication has been in existence, it has been the object of its conductor, to extend its circirculation, by every honorable and proper means. But he has not resorted, and will not resort, to other means that are deemed almost essential to the prosperity, if not existence, of many periodical publications. He has scorned to beg or buy, or exchange or sell puffs and undeserved praises; and therefore has gained nothing in popularity, or extended circulation, from the operation of that very general system, and nothing of favor or of money has been gained in the still more dirty profit that would have been perfectly available, by making this journal a puffing machine for all who would pay, directly or indirectly, for its use.

Neither are regular travelling agents employed to procure subscriptions by personal solicitation, and who, for some periodicals gain a hundred names by such importunity, where one would have voluntarily offered his support, upon mere knowledge of the existence and character of the works. There is nothing in the business itself of an agency to procure, in a proper manner, subscriptions to any publication, which is otherwise than respectable and honorable, or wanting in delicacy and propriety. But so many persons totally deficient in these qualifications, have been employed by northern publishers, and they have acted so much more like sturdy beggars, (to whom the solicited subscription money would be given as alms, and merely to get rid of their importunity,) than like gentlemen offering an exchange of equivalent values, that this kind of agency business has been long stamped with discredit; and few persons who have a proper degree of self-respect will risk incurring the suspicion and odium now attached to the business, by seeking subscriptions to any work, amongst strangers. Hence, the market is open only to publishers and agents who have no such scruples; and accordingly they profit well by the virtual monopoly. For such is the indolence of most men, and their unwillingness to refuse what is asked; (and especially does the remark apply to the people of these southern states,) that twenty subscriptions are made to publications, which are neither wanted or prized, because urgently begged for, face to face, where one would be gained without such personal solicitation.

Being debarred, by proper and sufficient considerations, from these modes of obtaining support for, and extending the circulation of the Farmers' Register, there remained one other, which is also usual, and which seemed free from any objection, save the cost in money, or possible risk or loss, to the publication. This was to spread abroad gratuitously specimen numbers, and to offer inducements to subscribers themselves, old and new, to render this good service, and to accept the profits, (for themselves or for others,) of the agents and the collectors whose employment for this publication has been abandoned. In many cases, the putting out some one volume as a specimen, even at a loss if considered alone, may gain subsequent and profitable circulation to a number of volumes. Acting upon this plan of making known the work to persons who would not of themselves seek the knowledge, thousands of separate numbers have been distributed gratuitously; and in pursuance of the same system, and from the beginning, and in the earliest and all the publications of conditions, new and joint subscribers have been invited by reduced terms, upon the expectation that all such who, after trial, might approve the work, would continue as subscribers at the regular and necessarily higher price of single subscriptions. Independently of the private interest and gain of the publisher, it is manifestly a gain to the public, and of course to each individual subscriber, that the circulation of the work, (if it be valuable,) should be extended as far as possible, to insure its stability and increase its usefulness.

But because the work has been, in this manner, and for these reasons, offered on certain conditions at prices much reduced below the regular and usual rate of single subscriptions, it has been erroneously and strangely inferred that the publication could have been afforded to all paying subscribers at the lowest named rate; and that those who did not choose to avail of the conditions of reduction, suffered the injustice and disadvantage of being over-charged.

If the means proposed and offered, had, before the commencement of the printing of vol. vii, induced a quadrupled or even trebled subscription, then, indeed, the price might have been reduced, and profitably, by one half to all subscribers, and with no other conditions than the making the reduced payments all advanced, and all sure, and thus relieve the publication of the heavy charges of collectors' commissions, postage, discount on uncurrent paper money, and all the numerous other pecuniary losses which are of daily occurrence, and enormous in their total amount. Such a change would be a most happy one, for the interest of the publisher, as well as for that of all his *paying* subscribers. It was in the hope of reaching this desirable end that the latter offers of deduction were made, and that a still more liberal offer is now risked. And without succeeding in some means of making payments more prompt and secure, the publication must sink—not for want of subscribers—but for the entire disregard of so many of them of their obligations to the publisher. Had no subscribers' names been stricken from the subscription list, except by their own proper order of discontinuance, the number would have been every year still increasing, and the publication would have been thrice as rich as it is, *in debts* from its negligent patrons. But the list has been diminished and would continue to be diminished under the former system, by the publisher's erasure of the names of debtors.

There are circumstances, not sufficiently (if at all) considered by the public, which cause heavy expenses to a magazine like this, which is and ought to be taken by subscribers only in entire volumes, which do not attend newspapers. Subscribers to the latter begin and discontinue at any times; and the publishers can expand or contract their issues precisely to suit the most fluctuating demand. Not so with this and similar publications. With the printing of the first sheet of each volume, the entire number of copies must be fixed; and the opposite dangers are threatened, of printing too few, or too many copies, for the subsequent demand. Heavy losses from both these opposite causes have been already sustained in conducting this publication; and were necessarily incurred, to make sure of supplying the actual demand. It will be plain enough to any who will reflect, that to supply a certain and previously known demand, 4000 copies of a volume could be afforded to be printed at a rate of subscription price, which if doubled, might be less profitable, for an impression of 1500 or 2000 copies, issued for an uncertain demand.

Upon all the grounds stated and referred to, it is earnestly desired by the publisher that every individual subscriber will avail of the offer made to him; and thus bring to the work directly a doubled subscription, and probably, indirectly, twice as many more.

Before quitting this subject of personal and private interest, the writer will use the occasion to remark on another erroneous opinion, which he has reason to believe is prevalent. This is, that this publication has been very profitable to the proprietor, and so much so that a large abatement from the former price and income, would still leave abundant profit for the capital invested, labor and risk.

It is very true that, if considered alone, and as a mere publisher's speculation, and not in its bearing on any other business or capital of the actual proprietor, this publication has been throughout productive of good profits upon its cost. And much larger have these profits been than the early expectations of the proprietor, or those of any of his friends, when he first proposed, and when he commenced the work. No one with whom he consulted then expected any considerable profit to be reaped, and nearly all predicted that loss would be the almost sure result of the undertaking. This is certain—that not another individual in Virginia would have incurred the actual and great risk of failure, and pecuniary loss, by making such an attempt. The incurring of such risk should not be overlooked in the estimate of what profit is justly due to the adventurer; but it is not denied that the pecuniary returns from the publication, if considered alone, have amply compensated both the risk and the expenses. If the public pay a sufficient price for the publication itself, the publisher has no right to count on more, upon any other account. He has no claim on the public for losses incurred thereby in other things. But these losses are not the less important to himself; and he will presume here to say, that if he had attended properly to his private affairs and previous employments, (which have been necessarily and greatly neglected,) and had never commenced the business of editor and publisher, he would have made much more profit and with much less toil and difficulty. He will never cease to prize highly the honor of having been the editor of the Farmers' Register—nor to value, beyond any amount of private profit, the public services which that work has been enabled by its supporters and contributors to perform. But so far as *money* is the value in question, the conducting of the Farmers' Register has not brought enough profit to pay for losses in other business thereby neglected, and the waste of other funds, caused by the necessary change of residence and of habits, as well as of pursuits.

RECEIPTS FOR THE SMITH FUND.

The subscriptions already made towards the "Smith Fund," proposed at page 500 of this volume, amount to about $1200. The editor will acknowledge in the Farmers' Register in the following manner, the several sums as received, and for which he will be accountable, until expended under the direction of the committee.

Subscribed and paid by

ED. RUFFIN, Petersburg, Va.	$100
GEN. JOHN H. COCKE, Fluvanna, Va.	75
THOMAS S. PLEASANTS, Chesterfield, Va.	100
REV. SIDNEY WELLER, Halifax, N. C.	100
WILLIAM J. DUPUY, Petersburg, Va.	30

Committee to manage the Fund.

EDMUND RUFFIN
JOHN H. COCKE
THOMAS H. PLEASANTS.

The fund, to the extent received, will be disposed of, without much more delay; and therefore those who may design to aid the object, are desired to act speedily. All contributions must be placed in charge of Edmund Ruffin, Petersburg, Virginia.

LEGISLATIVE AID TO AGRICULTURE.

No. 3.

Agricultural periodicals and school books.

According to the test which was adopted in the first of these numbers, which merges all the proper governmental action for aid of agriculture, into the providing and conveying of instruction, there can be few better modes than the causing the publication and general diffusion of cheap books and papers on agriculture. It is not designed here to argue in support of the value of reading, to all practical cultivators—nor to defend what is contemptuously called "book-farming." The observations which will follow are offered on the supposition that the value of the knowledge of agriculture to be derived from books, and the improvement to be achieved by the aid of the press, are fully acknowledged by all. The question is merely as to the cost at which such advantages may be conferred; and in this respect of cheapness, this mode of governmental action will bear comparison with any other.

Most of the agricultural reading furnished in this country is by periodical magazines and newspapers; and this is decidedly the most attractive and cheapest, and altogether the best mode for the small proportion of the agricultural community who have enough of the desire to be thus informed, to pay even so small a price for the benefit. But, in Virginia and the south, this demand is so limited, that probably not three individuals in a hundred landholders, either enjoy or have learned to appreciate this advantage. In the northern states, the more general demand has rendered printing much cheaper than in the south, and the consequent greater cheapness of agricultural papers serves to induce a greater number to buy and to read. But here, there exists not enough public spirit to cause a large demand, and without such demand, no periodical publication can be issued at less than double the price which would be ample under opposite circumstances. If the state government could beneficially aid in producing here the desirable results of a very cheap and very abundant supply and wide diffusion of such works, there would be few more efficient means for spreading the knowledge and stimulating the improvement of agriculture. A mere insurance against loss for a year or two, might be sufficient to induce a publisher to issue a journal at the lowest price: and when the large issue was once taken up by subscribers and readers, the measure might be safely left to its own support. There might, however, be difficulties in adopting measures for such a scheme: and there is an obvious difficulty in discussing them in this place. This branch of the subject will therefore be dismissed from further notice.

But there is another mode by which the state might well and easily interpose, by spreading abroad agricultural and other useful publications, to great extent, and with the most sure operation, and yet save money to the treasury, or to the fund for education, by the measure, instead of paying more for the benefit so derived.

For a long time there has been paid from the Literary Fund, for the expense of tuition in the primary schools, $45,000 annually. More recently, the annual appropriation for this object has been raised to $70,000, which sum is pledged to be continued. The school commissioners are limited to an expenditure of five per cent. of the whole appropriation, for the purchase of books for the pupils, which is $3500 a year; and, from that limitation having been found necessary, it is fair to presume that the whole of the five per cent. has been, and will be, generally so expended. Now the books bought for this purpose are, of necessity, of the same kinds of northern publications which are used to supply all the other schools of Virginia—proceeding from the fertile sources which every year send forth new editions, (or at least new title pages so marked,) and for which perpetual changes, as well as for the distinct works, every parent is taxed so heavily and incessantly during the time of the tuition of each of his children. These books must also be bought by the school commissioners at retail prices; and these prices, as will be afterwards shown, are at the least four times as high as the like or better selected works could be printed and sold for in Virginia. This last assertion, will, at first, appear incredible; nevertheless, its truth shall be clearly established.

Of the $3500 of the Literary Fund thus expended annually, one half may be supposed to be for books designed for pupils to learn to read. For this, the main object in view, they serve as well as any would. But the subject matter contained is generally useless, and in some cases hurtful; for this is one of the channels through which northern abolitionists have distributed their false doctrines, and endeavored to impress them upon the tender feelings and weak minds of young children. But put aside this ground of objection, and let it be supposed that no more evil than good matter of instruction is conveyed by these books, and that, in these respects, the opposite sides of the account stand balanced; still, their only good purpose, that of enabling the pupil to learn to read, could as well be effected through other books which would also convey useful information, and instruction. For example, suppose that all the reading books used for the younger pupils in the primary schools, were on subjects of practical agriculture, the mechanic arts, and things useful in domestic economy. The subjects read and studied in books during childhood and youth make the most lasting impressions; and while the boy was learning to read as well as by any other means, he would also be storing up information which would be of value to him throughout his future life and labors, and which might otherwise never come within his reach. But this would not be all. The attendance and devotion to study of the pupils who are sent to schools at the expense of the state are, unfortunately, very slight, and their services very irregular and short. Their books cease to be school-books as soon as the owner leaves school; and this probably happens in every case on the average, after one year's tuition. At present, the books are then useless; but in the supposed case, they would continue to be useful, in whosever hands they might fall. Even when carried home by a diligent and continuing pupil, the contents might attract the curiosity, and serve to instruct the father, as well as the son. In this manner, the waste and loss of the books so furnished by the state, (and such waste and loss must always be great under the very bad existing school system,) would conduce much more to the general good, than the direct and designed uses, as mere school books, have ever done. If only half of the appropriation, or $1750, were expended in the kinds of books recommended, small as that amount is, it would be as the distribution of widely but regularly dispersed seed, which would produce a future growth of knowledge, (which is both power and wealth,) exceeding in value a thousand fold, all the cost of the sowing. Even the amount of agricultural reading which this small annual expenditure would pay for, when fully used and well studied, (which this mode of distribution would insure,) could not fail to cause a great increase in the spreading of agricultural knowledge. But this gain will be the more highly appreciated, when it is considered that the whole of this new supply of instruction, would be furnished to a class of cultivators who otherwise would read nothing on the subject. In this manner, to create and diffuse a new desire for such reading would be another important operation of the plan; for when an interest was once felt, and an appetite for information excited in such readers, they would, at their own cost, continue to seek and to profit by the instruction which is to be gained from similar sources, and at so cheap a rate.

So much for the worth of the results of this humble plan; now for its expense and its economy, considered merely in a pecuniary point of view.

Because books printed in the northern states, especially school-books, almost exclusively supply the demand of Virginia, and because the few books which are printed in this state are usually higher priced, and yet yield but little (if any) profit to the publisher, it is therefore, and generally inferred and admitted that books cannot be here printed and furnished with fair profits, as cheaply as is now done by northern publishers. This is very far from being true. The only reason why books are not printed in Virginia, at lower prices than those of the like kinds sent here from the north, is because there is not sufficient sale to pay for the enterprise, whether at the lowest or the highest prices. The principal publishing booksellers of the north possess a virtual monopoly of all the southern market—a monopoly, which, though created by circumstances, and not by law, is much more operative, and will be more difficult to break down, than any made by legal enactments and designed governmental policy. The manner in which this monopoly is fixed and operates upon the consumers, has been already treated of in a former part of this journal, (at page 263. Vol. VI,) to which the reader is referred. It will be enough here to show, and that will be done clearly, that if sufficient demand of purchasers existed, such as the northern publishers for southern supply now enjoy, that printing, and the manufacture of books, can be executed so cheaply here, as to furnish like work at prices far below those now paid for the present and usual supplies, and for which hundreds of thousands of dollars, are every year paid from the south to the northern publishers.

It is not necessary to fatigue the reader with explanatory details of the business of printing, to obtain his conviction, and ready admission, that the cost of printing books will be diminished, and in a greatly increased ratio, according to the extent of the impression, or number of copies printed for each edition. The "composition," or arrangement of the types, and putting them in proper manner on the press, in a small edition, or number of copies, forms the far greater part of the whole cost. But that element of cost is precisely the same for an impression of 300, or for 30,000 copies of the work. Therefore, the item which makes the principal part of the expense of each copy of a small edition, sinks to the least, and to almost nothing, in one of a very large edition. Thus, a volume, for which the mere printing would cost 50 cents, if one of an edition of 500 copies, would be as well paid for at 5 cents, if 20,000 had been contracted for.

For the purpose of making these statements more clear to the readers who may be well inclined to aid in correcting the existing evil—and also the more open to correction to any others who may be disposed to question or deny the results—some particular estimates have been obtained from a printer of the best qualifications, so as to show at how much lower prices the cheapest of northern books might be printed here, provided there existed a certain demand for editions of 10,000 copies.

One of the ordinary reading books now in common use in the English schools of Virginia, was taken, at hazard, for the purpose of estimate. It is the 'Eclectic Reader' of 324 pages. It is plain print, (without illustrations or engravings;) and in plain binding, it sells in our bookstores, at retail, at $1 the copy. This particular description of so unimportant a book is deemed necessary, because, according to usage, it will scarcely remain in existence a year hence. It will by that time have performed its intended office, of being *sold* to supply every school whose accommodating teacher will require its purchase; and it will then be superseded by a newer edition, or some other compilation of like purpose and value, and of like transient reign. We speak not of its contents, which probably, like its price, are about a fair average of the general supply. Of this work, to be printed as well and on as good paper, a printer in Virginia, could furnish in sheets an edition of 10,000, for $1527, which is less than half a mill per page, or per copy, about - 15 cents.

Add for binding, suppose - -	12
	27
Retail price of the northern copies -	100
Difference per copy - -	73 cents.

Another still more striking comparison will be offered with other northern publications which are universally known, and which have been generally supposed to be sold at a loss by the religious and benevolent institution which furnishes them, and to have reached the *ne plus ultra* of cheapness. These are the religious tracts published by the American Tract Society, in Philadelphia. The standing price of these publications, in pamphlet form, in small quantities, is 1 cent for 10 pages; and by large quantities, 1 cent for 15 pages. Similar work can be executed in editions of 10,000 copies, under all the present disadvantages of the printing business in Virginia, and would afford ample profit to the printer, at the still lower price of 1 cent for every 20 pages. When it is considered that the heretofore limited and uncertain demand for printing in the south necessarily makes the labor more costly to the undertaker, and the best services and talent more difficult to be obtained—and that with enough enlargement of business, the expenses of printing could be as much reduced as they already have been in the northern cities—the foregoing comparison of prices will be still more remarkable. The estimate of expense and of pri e, here, is made at the necessarily higher rates heretofore and usually charged for book-work in Virginia, executed by small hand-presses; and the northern editions, and particularly those of the American Tract Society, are produced at less cost by one third, by means of cheaper materials and better and cheaper workmen, large presses, worked by steam or by horse-power, stereotype plates, and editions which sometimes extend to 100,000 copies, or more. A printer in Virginia, after acquiring these additional and great facilities, (which certainly will follow sufficient increased demand for his products,) could, in proportion, still more reduce his prices, without lessening his profits. But at present, and under all the existing disadvantages caused by the peculiar existing circumstances, a printer in Virginia could make greater profits than any of his brethren here have ever done, by printing and selling works in the form and manner of the publications of the American Tract Society, at prices lower than these are sold for. Thus will appear, (what few persons who have subscribed to aid this great benevolent and excellent plan would have suspected,) that the works of this society are, or ought to be, very profitable to the publishers, as well as benefical to the consumers.

From these general statements, (to which no contradiction is feared, and of which the truth can be tested by reference to any intelligent printer,) it will sufficiently appear, that nothing but sufficient demand is required to make the trade of manufacturing books in Virginia highly profitable. But it is impossible, in the present state of things, for any individual to break through the existing monopoly possessed by northern publishers, or even to venture to compete with them. Suppose one were so bold and imprudent as to incur this risk, and were to publish some good school-book, which is the kind for which there would be the best chance for selling. If he prints a small edition, the price must necessarily be higher than the prices of those already in possession of the market; and of course his work could not come into competition. If he issued a very large edition, and with the view of being enabled to sell at a lower price than any other, still, for want of all the arrangements and means so long and systematically used by others, he could not by possibility sell as many copies as would pay half the cost. These truths are so well known to all connected with the trade, that it is very rarely, and under some very peculiar circumstances, that any printer in Virginia will dare to publish a book for sale; and even every southern author, to get his work before the public, either for his honor or his profit, must, of necessity, submit to have it issued, and introduced to his own state, by a northern publisher, even though he could have the printing done as cheaply, and more faithfully, at home.

It may be considered that the means of remedy proposed for this evil condition of things, are very feeble, and would be but slightly operative. This is admitted; but nevertheless, as an auxiliary or even single means of diffusing agricultural knowledge, the measure would be as important as its exercise would be cheap. Suppose the exercise of governmental encouragement and economy united, was limited to the expenditure of the regular annual cost of books, of $3500, which might serve to supply enough agricultural reading books to all the primary schools for four years use, and (supposing books for reading to be one-half of all furnished,) this would save to the fund just half that amount, or $1750. So much of the effect, the saving of expense, it is presumed would not be objected to by the most frugal and sparing, or most fastidious of legislators. Suppose for greater cheapness, the agricultural tracts to be issued in the usual form of the religious tracts, or as neat and well covered pamphlets, and at the ample price of half a mill per page, and $3500 would pay for 10,000 copies of as many works as would amount to 500 pages altogether; or any one book of 100 pages would cost only five cents the copy. This would be for one, and so small a matter, a great saving to the education fund, and to agriculture a great benefit, in the wider diffusion of so much instruction.

Further: if the books to be thus republished by order of the state, were judiciously selected by a competent tribunal, (which of course ought to be done,) and were as suitable for the use of schools as any others, their great cheapness and high character would insure their being received into all schools of the state, if not of other southern states. And for the chance of meeting this additional supply, the publisher could afford to issue many thousands of copies more than the state had contracted for. Thus the joint benefits of spreading agricultural instruction, the guarding against unnecessary expense on the part of thousands of private individuals, and the building up a profitable manufacture, and both a home and export trade, would all be aided, by the same measure, and more and more with the continuance of the system. Views of economy and profit would alone soon make manifest the advantage of extending such a mode of publication to the best of other kinds of books needed in schools; and even if public spirit did not forward the result, private interest and economy would soon cause these cheap and standard books to be sought for, and used in every southern school. Putting aside the more important considerations of aiding the diffusion of knowledge, and especially of agricultural knowledge, this anticipated result would be highly important and valuable to the manufacturing and trading interests of the state. In very large editions, the mere cost of the blank paper becomes the greater part of the whole expense; and, therefore, if the gross amount of $100,000 should ultimately be so received by the publishers of cheap books, more than $50,000 of that amount would be paid to our paper manufactories. This is also a matter of no small importance to the manufacturing and commercial interests of Virginia; and well worth the consideration and care of the legislature, even if the interests of education and of agriculture are altogether disregarded.

EXTRACTS FROM THE ADDRESS TO THE AGRICULTURAL SOCIETY OF FREDERICKSBURG, ON ITS 21ST ANNIVERSARY.

By James M. Garnett, President.

* * * * * * * * *

Another experiment was with the Irish potato, by drawing the shoots from the whole tubers when they were about four or five inches long, and setting them as is now generally done in the Carolinas, with the sweet potato. The drought and heat again prevented me from ascertaining more than the following facts: that the shoots or sprouts will grow with as much certainty as cabbage plants—will produce quite as much (at least they did so in this trial,) as the whole roots; and that the practice will save both some seed and labor; for the shoots can be drawn and set somewhat sooner than the whole potatoes can be cut into small pieces, dropt and covered. In regard to this crop it is worth mentioning, that it failed in every part of the state from which I have received any accounts, except in two cases in my own neighborhood. In both these, after the ground was well prepared, the potatoes were deeply covered with straw or leaves, and left undisturbed until they were dug. Both produced, as I have been assured, quite as well as usual, and the fact, I think, proves conclusively, that this method is best; at least to the extent to which our own farms will furnish straw and leaves enough to cover the potatoes, since the mere labor of collecting and covering will not exceed, if indeed it will equal, that of the culture usually given in any of the other methods. The covering plan saves all work, but the first, at the same time that it manures the land, and secures that degree of moisture without which no cultivated crop can long withstand the effects of those frequent and excessive droughts to which our climate has been subject for several years past. Our sufferings from this agricultural scourge, especially during the past season, have thoroughly convinced me of the following facts: that guinea-grass, lucerne and orchard-grass, (as in the order named,) resist drought better than any others yet known to me; and that the single coulter, freely used, during the early growth of corn, is worth all other implements in present use, put together, for protecting it against the destructive influence of long continued dry and hot weather.

The experiment from which I expected most advantage was made with six varieties of white corn—all said by their respective admirers to be "the best in the world;" and one variety of the yellow kind called "Dutton," which seems to have borne off the palm of superior excellence "down east," and as far south as New York. All the kinds were planted alongside of each other, on the 10th of last April, and as well as I could judge, in similar soil of equal fertility. Although I knew they would mix from such proximity, and of course that the least productive would derive some benefit from that which was most so; yet I did not believe it would be so great, in one trial, as entirely or very nearly to equalize their products, or prevent a satisfactory development of their characteristic differences. But here again the excessive drought and heat disappointed me. All suffered so much that no conclusive comparison could be made in regard to more than one or two of their peculiar qualities. The Dutton corn showed tassels and shoots on the 20th of June and silks on the 29th. None of it grew more than four or five feet high, and gave so little promise for a general crop that all of it was used at our table. This single trial, I acknowledge, is insufficient to justify an unqualified condemnation; but so far as it goes, it authorizes the conclusion, that it will be far less productive in our climate than any of the large varieties yet cultivated among us. It is certainly what we southerners call a "dwarf corn,"—none of which kinds, although numerous, have ever yet proved very prolific, and are not cultivated, except for early use in the unripe state. The golden Sioux, first introduced among us by Mr. Skinner, the editor of the American Farmer, has heretofore proved the *earliest*. But the Dutton, for aught I know, may have a better claim to preference, and therefore I will say nothing to impede a fuller and fairer trial of a corn with such high pretensions—only adding the caution, not to try it on a large scale.

As to the white varieties tried in my experiment, a few tassels were seen, on the 9th of July, upon what I shall call the Carmichael corn, that being the name of a gentleman in Queen Ann's county, Maryland, who sent it to me, and who is the same that first brought into notice the twin-corn, which I have cultivated for three or four years, in preference to any other I know. This kind also began to tassel and shoot on the same day—the other four varieties not until seven or eight days later, and then so nearly together that I did not mark the difference in time, it being too small to be worth noticing. Of these last four, it is proper, by way of caution, to mention, that the Baden corn was one. It is the kind so widely distributed last spring by members of Congress, under the one name of "*Baden*," although in the parcel sent to me, I counted four distinct varieties, showing that little or no care had been taken in selecting the kind so called, although all perhaps had been sold, in the first instance, under that name, and at a higher price than common. I know well the difficulty of keeping any variety pure, for no grain mixes so readily nor at so great a distance as corn, but I also know that it may be done, as I have seen several instances of it, and the Dutton corn is one, for out of a quart of seed sent to me I did not find a single grain of a different kind.

I made no attempt to ascertain, as I had first intended, the relative productiveness of the different kinds used in my experiment—the drought having rendered it impracticable, as it did every other fair comparison I wished to make of their other qualities. In regard to the Dutton corn, I was satisfied from this trial, as well as by several others reported to me last year, that it never probably can become a general crop in Virginia. To judge however, from appearance, it is heavier than any of our white corns, except the Madeira, so called from the circumstance of its being cultivated many years ago, chiefly for the Madeira market. Why the culture is not continued, I cannot imagine, as it is a variety which is both very early and very productive, at the same time that it bears thicker planting than our common kinds. But since corn is the chief staple in the greater portion of Virginia, *the greatest produce per acre* is evidently the principal, although not the only thing to be diligently sought after and ascertained, for the most productive will always be found the most profitable. That this variety will be known in the course of a few years, I think there is every reason to hope, from the numerons trials now making to determine this point; and that it will be found among the white kinds, I have no doubt. All of these are early enough for the tide-water portions of the state, which is the corn region; and most of those that I have noticed are more productive than any yellow variety of which I have any knowledge. Those kinds have never, I believe, sold more than ten per cent. higher than the whites, and that only in the northern and eastern markets, whilst the best of the latter kinds will be found, unless I am greatly deceived, to exceed the yellow in productiveness, more than twenty per cent.; and in *taste*, (if southern palates were to be the standard,) double or treble that amount. Suffer me here, to give a word or two of caution to buyers, against those who claim to be the lucky discoverers of the best kinds of corn. If *they* ask some two or three hundred per cent. more than the general price of our common varieties, the purchasers may be perfectly sure—either that they are humbugged, or that the seller is one of those Shylock fellows who would see you and yours starve to death, without the least compunction, if he could only make money by it, and escape being tried for murder. * * * * *

(To be continued.)

For the Farmers' Register.

MONTHLY COMMERCIAL REPORT.

The business of the past year has terminated much more satisfactorily than that of its predecessor.

The commercial operations in Virginia have been peculiarly fortunate. Shipments of its principal staple, tobacco, yield larger profits than have been realized for any previous year since 1820, and more than counterbalance the heavy losses attendant on the convulsions of 1837. This result has been produced, however, by the extensive failure of the crop of 1838, and, from present appearances, the small quantity produced will yield as much money as a full crop would in ordinary times. The present range of prices is \$7 to 16, including all sorts.

Cotton has advanced about one cent in price; and the present quotations in Petersburg are $11\frac{1}{2}$ to $12\frac{1}{2}$ cts., including none of fine quality—the crop being inferior. A similar advance has taken place in all southern markets, founded on a belief that the crop will prove 200,000 to 300,000 bales less than the returns of last year exhibit. Foreign markets have also improved, but are not yet such as to warrant the prices paid here.

There has been little variation in wheat and flour. The former commands 160 to 170 cents. Flour (canal) \$7⅞ to 8. Petersburg mills \$8¼ and Richmond city 8⅜. Although prices are advancing in England, with a prospect of low duty, little disposition is evinced to venture to so precarious a market, where a slight decline in price subjects the importer to an enormous increase of duty. The product of the last crop in Virginia considerably exceeds the estimates which were formed at the period of harvest.

Corn is worth about 75 to 80 cts. Pork \$8¼ to \$9. X.

January 7, 1839.

CROPS ON THE EASTERN SHORE OF MD.

Queen Ann's county, Md. Dec. 14, 1838.

To the Editor of the Farmers' Register.

As you express a desire to know the state of the products of the year, in the different sections of the country, I can say that the crop of wheat, in the few upper counties of the Eastern Shore was good, as far as it was sown, perhaps above the ordinary product. The crop of oats very short—the crop of corn diminished by more than a half, and the root-crop hardly worth gathering.

TO CORRESPONDENTS AND CONTRIBUTORS.

It is unnecessary to repeat here what the editor has so often stated in former volumes, and which, moreover, is manifest to every reflecting reader, that the great and main value of the Farmers' Register has throughout consisted of the original communications of the many and intelligent contributors to its pages. Whatever the editor has written or done, or whatever any one man can do, even if possessed of far greater abilities, but confined and oppressed by the like unceasing toil, is comparatively of small account, and utterly insufficient to maintain, for a single year, the proper value and interest of an agricultural journal. All those readers who have so essentially aided this work formerly by their writings, and the very far greater number who *ought*, but have failed to render such service to the public, are earnestly requested to give full and proper consideration to these truths; and then to glance over the table of contents of this now closing volume, and see how little has been done, compared even to the former and always too scant aid of the fellow laborers of the editor in the great work of diffusing agricultural instruction, and thereby improving the condition and profits of agriculture. Those who have formerly so ably, and profitably to the public, offered to their brother farmers their lights and experience in agriculture, through the pages of this work, but who have since relaxed or suspended their exertions, must return to the task; and also invite, and bring in, new hands to share with them the labor and the honor. If every subscriber to this journal, would freely communicate whatever useful facts he knows, and which are not generally known to others, and if such course were pursued regularly, nothing more would be wanting to raise the Farmers' Register to the highest rank of public utility and value; and no greater benefit could possibly be conferred on agriculture, and agricultural interests, by any action of private individuals. Yet how easy would be the performance of such duty; and every one would be speedily and fully compensated for his own share of the labor, in the new value he would derive from the communications of others. Without such assistance, liberally furnished, no agricultural journal of character can long maintain its usefulness, or even its existence.

In looking back on the labors of the last year, the editor has not to reproach himself on the score of failure to do his part of that labor which he had hoped would have been, but has not been, fully shared in by others. The more that others have relaxed their efforts, the more has necessity required that he should exercise his pen; though without the encouragement and cheering aid of companionship in labor, or of any sufficient evidence of concurrent interest, or sympathy, on the part of those for whose benefit his efforts were made.

In addition to the seemingly growing apathy of most of the former contributors to this work, several among the most valued have been recently removed by death, within the space of a single year—and all from the generous south, to the liberality of which the Farmers' Register owes *so much*—but for literary or other labor, *so little*. One of these was that warm hearted and public-spirited old man, Nicholas Herbemont, whose kindly and benevolent feelings, no less than his intelligence, were conspicuous in all his writings. The fate of two others to whom this work also owes much, was the more to be lamented on account of the peculiarly distressing and horrible circumstances of their deaths. Both fell victims to that system of wholesale exposure and sacrifice of life, for private gain, which has been established by the owners of steamers. Hardy B. Croom, with his family, perished at sea by the shipwreck of the Home. Farquhar Macrae met a like deplorable death in the destruction of the Pulaski; and his life was sacrificed by his generous self-devotion, which made him yield his place of security, on a fragment of the wreck, (yet in vain,) for the purpose of saving an aged and feeble stranger and fellow-sufferer.

CONDITIONS OF THE FARMERS' REGISTER FOR VOL. VII. PRICES STILL MORE REDUCED, FOR PUNCTUAL OR ADVANCED PAYMENTS.

I. The Farmers' Register is published in monthly numbers, of 64 large octavo pages each, and neatly covered, at \$5 a year, payable in advance. Or, for \$5 may be purchased *two copies* of the same current or forthcoming volume, if so ordered and paid for in advance, (or at the time of making the subscription,) in current money, (as described below,) and without loss or deduction for postage, or any other charge to the publisher.

II. Subscribers now on the list, who have already paid the regular subscription price of \$5 in the manner above required, for a single copy, shall have the privilege, upon sending a *post-paid* order, of having a second copy of the same volume sent to any NEW subscriber, without further charge, for that volume.

III. A like privilege will be allowed to every old subscriber who has not yet paid, but who shall do so, as above, before the issue of the 2d number of the 7th volume; thus in effect REDUCING TO HALF PRICE THE COST OF THE WORK TO EVERY SUBSCRIBER, OLD OR NEW, WHO MAY CHOOSE TO AVAIL OF THE OFFER.

IV. If, however, no more than one copy is ordered, the subscription price will still be, as heretofore, $5 the volume; as it is not designed to permit any subscription debt, or payment, to be made for less than $5. And if an order is sent for two copies, without compliance with the conditions annexed, only one will be sent.

V. The price of back volumes, as heretofore, is $5 for one alone, $10 for any three together, and in the same proportion ($3.34 cents for each,) for any number of volumes, except vol. I., which is at $6, and to be furnished only as part of a full set.

VI. ALL MAIL PAYMENTS MUST BE MADE IN NOTES, OR CHECKS, OF PAR VALUE IN VIRGINIA, or of a CITY and SPECIE-PAYING bank of the state in which the subscriber resides.

VII. The risk of loss of payments for subscriptions, sent free of postage, which have been properly committed to the mail, or to the hands of a postmaster, is assumed by the editor.

VIII. All letters to the editor in regard to the Farmers' Register must be post-paid—except such as contain articles for publication.

IX. If a subscription is not directed to be discontinued before the first number of the next volume has been published, it will be taken as a continuance for another year. Subscriptions must commence with the beginning of some one volume, and will not be taken for less than a year's publication.

X. The mutual obligations of the publisher and subscriber, for the year, are fully incurred as soon as the first number of the volume is issued; and after that time, no discontinuance of a subscription will be permitted. Nor will a subscription be discontinued for any earlier notice, while any thing thereon remains due, unless at the option of the editor—(or in obedience to the regulations of the Editorial Convention, copied below.)

General Regulations adopted by the Editorial Convention.

The following resolutions of the Editorial Convention of Virginia, will hereafter form part of the Conditions of the Farmers' Register, and will be strictly observed.

1. "All subscriptions shall hereafter be considered as incurred and due in advance, and for a year's publication, unless specially ordered for a shorter time, and paid for in advance for that shorter time, when so ordered.

2. "No publication shall be sent to the order of any new and unknown subscriber, unless paid for in advance, or satisfactory reference be made to some known and accessible person in regard to the subscriber or his payment. But, in case of an order for a publication, without payment, from a new subscriber who is unacquainted with the conditions, a single number may be sent, containing, or accompanied by, a copy of this regulation.

3. "The names of all subscribers, whose ability to pay may be unknown to the publisher, and who may remain indebted on open account at the end of two years, from the time when the advanced payment was due, shall be erased from the list of subscribers."
